ABSTRACT

The Illinois Department of Transportation (IDOT) and Federal Highway Administration (FHWA) propose a transportation solution to improve regional and local travel, improve access to employment, improve safety for all users, improve modal connections and opportunities, and improve facility deficiencies on Interstate 290 from west of Mannheim Road on the west to Racine Avenue on the east, located in Cook County, Illinois. This Final Environmental Impact Statement (FEIS) considers four build alternatives, along with a No Build Alternative. The alternatives are identical in length at approximately 13 miles. There are no impacts to wetlands, High Quality Aquatic Resources, or federal- or state-listed species for any of the build alternatives. No displacement of residential or commercial structures would result with any of the build alternatives. There would be 0.40 acre of incremental permanent impacts to Waters of the United States, located at the Addison Creek and Des Plaines River crossings, for all build alternatives. A Section 4(f) *de minimis* finding at three public parks and a Section 4(f) exception at one public park were approved with receipt of written concurrence from the Officials with Jurisdiction.

Based on the analysis and evaluation contained in the FEIS and after careful consideration of all the social, economic, and environmental factors contained in the FEIS with input received from other agencies, organizations, and the public, it is the decision of the FHWA to approve HOT 3+ & EXP & HCT (also referred to as HOT 3+), which is one High Occupancy Toll Lane and three General Purpose lanes in each direction, with provisions for Express Bus service and High Capacity Transit (Blue Line Rapid Transit or Bus Rapid Transit extension) as the Selected Alternative.

June 30 2017
Date of Approval of FEIS and ROD

For Federal Highway Administration

[1] IDOT's signature commits it to implement the project as described in the FEIS, including all mitigation measures contained therein, and serves to recommend to FHWA to approve the FEIS and ROD.

3.18 Permits and Approvals 3-314

3.19 Summary of Environmental Commitments and Mitigation 3-315

4.0 AGENCY COORDINATION AND PUBLIC INVOLVEMENT 4-1

4.1 Outreach Requirements 4-1
4.1.1 Federal and State Requirements 4-1
4.1.2 Stakeholder Involvement Plan 4-2
4.1.3 Project Study Group 4-2

4.2 Corridor Advisory Group/Task Force (CAG/TF) Meetings 4-3

4.3 Stakeholder, Community, and Agency Coordination 4-10
4.3.1 Stakeholder Outreach 4-10
4.3.2 Community Coordination 4-13
4.3.3 Agency Coordination 4-15

4.4 Public Hearing 4-18

4.5 Summary of Comments and Responses on the DEIS 4-19
4.5.1 Federal Resource Agency Comments 4-20
4.5.2 Local Governments 4-22
4.5.3 Public Organizations 4-23

4.6 Conclusion 4-23

5.0 COMPARISON OF ALTERNATIVES SUMMARY 5-1

5.1 Alternatives Carried Forward 5-1
5.1.1 Accommodation for High Capacity Transit 5-5
5.1.2 Comparison Matrix of Alternatives 5-6

5.2 Performance Comparison 5-12

5.3 Social/Economic and Environmental Impacts Comparison 5-14
5.3.1 Social/Economic Impacts (including Environmental Justice) 5-14
5.3.2 Section 4(f) Resources 5-17
5.3.3 Visual Resources 5-19
5.3.4 Air Quality 5-20
5.3.5 Special Waste 5-21

5.3.6 Natural Environment 5-22
5.3.7 Traffic Noise 5-22

5.4 Other Considerations 5-24
5.4.1 Tolling Revenues 5-24
5.4.2 Tolling and Pricing Policy and Strategies 5-24
5.4.3 Construction Staging 5-26
5.4.4 Construction Cost 5-26

5.5 Preferred Alternative 5-27
5.5.1 Achievement of Stakeholder Goals and Objectives 5-27
5.5.2 Quantitative Comparison of Alternatives 5-32
5.5.3 Implementation Flexibility 5-35
5.5.4 Refinements to HOT 3+ Included in the Preferred Alternative 5-36
5.5.5 Conclusion 5-37

Record of Decision on the Interstate 290 (I-290) Eisenhower Expressway Project in Cook County, Illinois by the Federal Highway Administration

1.0 Background

The Eisenhower Expressway (I-290), originally constructed as the Congress Expressway, was one of the first multimodal facilities in the United States. Opened to traffic in sections beginning in the mid to late 1950s, this facility was designed and constructed according to early standards that were newly created for the interstate highway system.

During the original construction of the Eisenhower Expressway, the Chicago Transit Authority (CTA) Garfield Park rapid transit branch was removed and replaced with what is now known as the Blue Line Forest Park Branch. This heavy rail transit line was constructed parallel to the Eisenhower Expressway, running along the south side of the roadway or in the median. As part of the construction of the Eisenhower Expressway, the freight railroad owned by Baltimore & Ohio Chicago Terminal Railroad, which ran at-grade along the current alignment of the Expressway, was grade-separated and relocated adjacent to the south side of the CTA tracks, sharing the same "cut" with the CTA and the expressway from east of DesPlaines Avenue to Central Avenue. This freight rail line is now owned and operated by CSX Transportation. This section of rail is part of CSX's Altenheim Subdivision and includes the right-of-way for three tracks, including two continuous tracks and a third intermittent track. A portion of the former Chicago, Aurora and Elgin electric interurban railway was also relocated at Forest Park as part of the original expressway construction, but passenger service on that line was discontinued in 1957.

West of Mannheim Road and east of Austin Boulevard, I-290 has four lanes in each direction. Between Mannheim Road and Austin Boulevard, I-290 has three lanes in each direction. This reduction in lanes and reduced capacity has been a long-standing source of safety, operational, and capacity concerns.

Since its original construction, I-290 has undergone periodic resurfacing and maintenance throughout the corridor. In 2001, the Hillside Interchange Reconstruction Project, located on the west end of the Study Area, was completed. This project was a spot improvement that addressed weaving and access to the Mannheim Road Interchange, and in doing so, addressed safety and operations at I-88's connection with I-290 and improved connections with Mannheim Road. While weaving conflicts on eastbound I-290 were removed by the addition of the eastbound collector-distributor roadway, the project did not address capacity needs along the I-290 mainline. In 2010, 27 miles of I-290 from Thorndale Avenue to I-90/I-94 were resurfaced and 37 bridges were repaired.

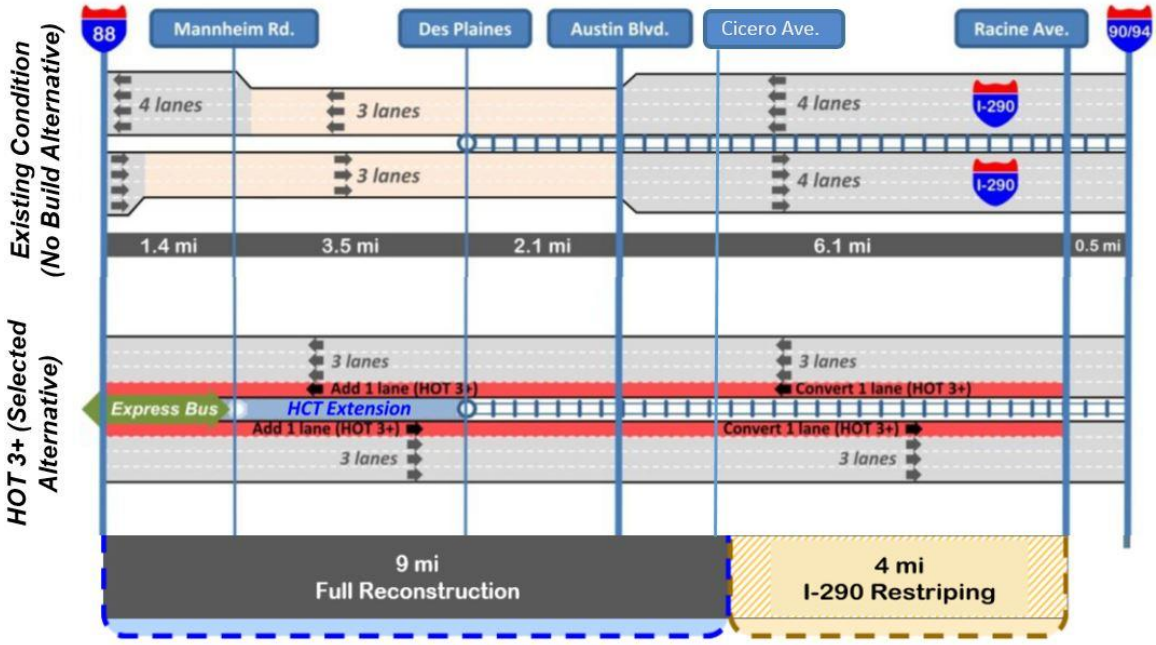
In 2012, the Illinois Department of Transportation (IDOT) initiated a Phase I preliminary engineering study for the I-90/I-94 and I-290 Jane Byrne Interchange, whose western study limits extend to Racine Avenue on I-290. This improvement project includes widening of the northbound-to-westbound ramp from I-90/94 to I-290 and the eastbound-to-northbound ramp from I-290 to I-90/I-94 from one to two lanes, as well as multimodal transportation system improvements, including wider sidewalks and improved access to public transit.

The I-290 Eisenhower Expressway is identified as a fiscally constrained major capital project in the region's metropolitan transportation plan adopted by the Metropolitan Planning Organization (MPO) Policy Committee, which is the designated MPO for the northeast Illinois region.

2.0 Decision

This Record of Decision (ROD) is the official decision document that concludes the National Environmental Policy Act (NEPA) process. Through this ROD, FHWA grants the state of Illinois approval to proceed with final design, completion of acquisition of needed right-of-way, and construction of the I-290 Project. This ROD is executed in conformance with the Council on Environmental Quality (CEQ) regulations implementing NEPA (40 CFR Part 1500) as well as Federal Highway Administration's (FHWA's) own regulations (23 CFR Parts 771 and 774). This ROD documents FHWA's compliance with NEPA and identifies additional requirements that must be met to proceed with the project. The decision is based on analyses contained in the Draft Environmental Impact Statement, issued December 30, 2016, and the comments of federal agencies, members of the public, and elected officials.

This ROD approves HOT 3+ & EXP & HCT, as described in Section 3.0 of this ROD and Section 5.0 of the Final Environmental Impact Statement (FEIS), as the Selected Alternative. It was selected following the evaluation of four mainline build alternatives in addition to the No Build Alternative and was identified as the Preferred Alternative in the DEIS, located generally within the existing I-290 right-of-way. Several key factors were taken into consideration for the alternatives evaluation, including socioeconomic and environmental impacts, travel performance, and stakeholder and agency input.



The Selected Alternative is an approximately 13-mile long, east-west oriented, eight-lane divided limited-access roadway with a western terminus west of Mannheim Road in Hillside, and an eastern terminus at Racine Avenue in Chicago. FHWA, in cooperation with IDOT, determined that the Selected Alternative accomplishes the project Purpose and Need as identified in Section 1.0 of the FEIS, has lower overall socioeconomic and environmental impacts as compared to the other three build alternatives evaluated, and incorporates stakeholder input.

In the event of any differences in wording, the ROD takes precedence over the FEIS.

3.0 Description of the Selected Alternative

The Selected Alternative is **HOT 3+ & EXP & HCT.** This alternative consists of adding one High Occupancy Toll (HOT) 3+ (three or more occupants per vehicle or transit vehicle required for non-tolled use, or one/two occupants per vehicle paying a toll) lane in each direction to I-290 between 25th Avenue and Austin Boulevard. The Selected Alternative also includes conversion of one existing general purpose lane in each direction from Austin Boulevard to west of Racine Avenue to HOT 3+ use, and provisions for express bus service (EXP) and high capacity transit (HCT), which includes a heavy rail or bus rapid transit extension. Figure 1 shows the configuration of the Selected Alternative as compared to the No Build Alternative.

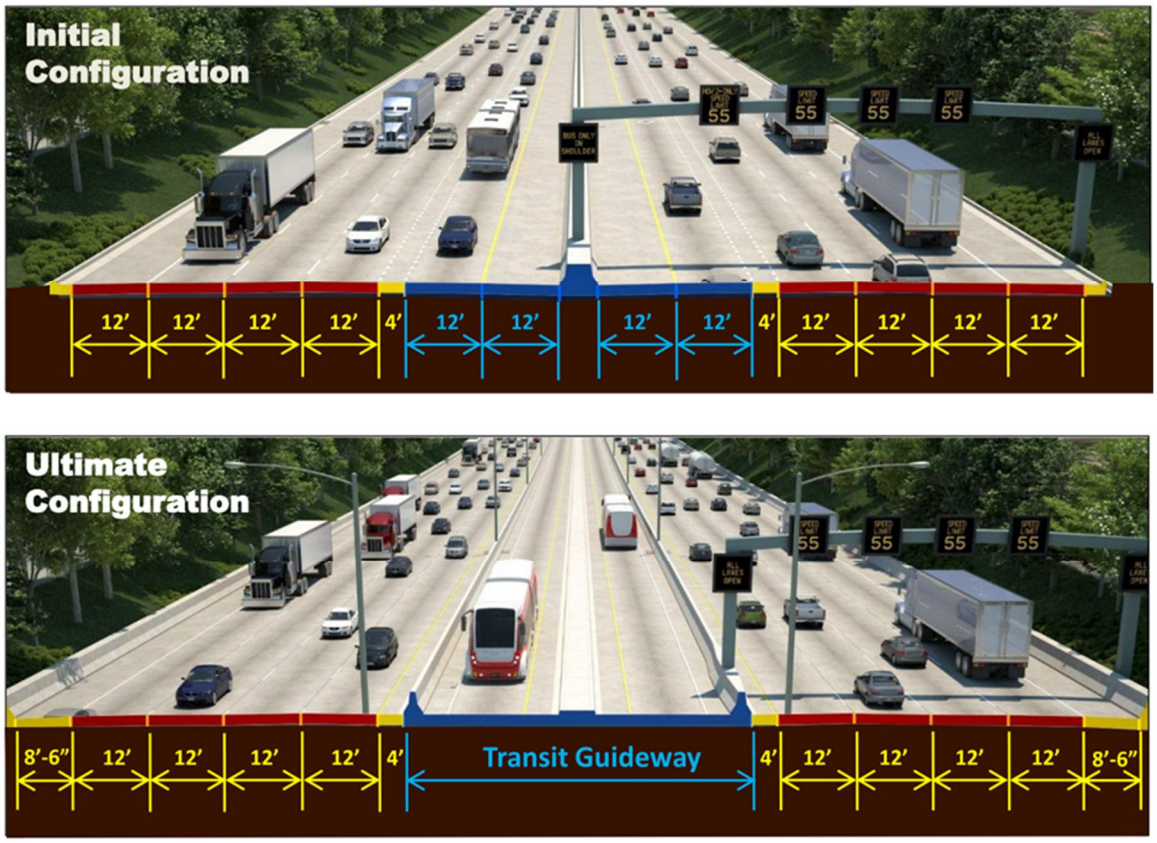


Figure 1. Selected Alternative

The 9-mile section from west of Mannheim Road to east of Cicero Avenue will require full reconstruction of the existing I-290 mainline pavement to address the purpose and need and to accommodate additional lanes. All existing interchanges and overhead highway and railroad bridges would be reconstructed, with the exception of the Mannheim Road interchange and Westchester Boulevard bridge which would remain in their current configuration. Existing bridges over Addison Creek and the Des Plaines River would be reconstructed, and an additional HOT 3+ travel lane in each direction would be constructed between east of Mannheim Road and Austin Boulevard. A new east-west shared-use path running parallel to I-290 is proposed from DesPlaines Avenue to Austin Boulevard, and improved pedestrian and bicycle accommodations are included in the reconstructed overhead highway bridges as well as reconstructed bicycle and pedestrian crossings at Home and Lavergne avenues.

Provisions are included in the I-290 median for initial accommodation of express bus service in the inside HOT 3+ lanes, and future conversion of the median space to accommodate a high capacity transit extension from DesPlaines Avenue to Mannheim Road (Figure 2). Improved connections to public transit, including station access and bus connections to the CTA Blue Line are included. Cross-road bridge clearances over the CSX Railroad between Circle Avenue and Austin Boulevard shall be improved to a minimum 21-feet 9-inches. A total of 5.972 acres of new right-of-way (ownership) and permanent easement is required for the improvements, comprised of acquisitions of property near 25th, 1st, DesPlaines, Circle, and Harlem avenues, as well as obtaining a 10-foot-wide strip of right-of-way from the CTA from west of Circle Avenue to east of Austin Boulevard; otherwise, the proposed improvements are contained within existing public highway rights-of–way.

Figure 2. Convertible Expressway Section – Initial and Ultimate Configuration

In the 4-mile section from Austin Boulevard to Racine Avenue, one lane in each direction would be converted from general purpose use to HOT 3+ use. Reconstruction of the 8-lane section is required from Austin Boulevard to east of Cicero Avenue. From east of Cicero Avenue to Racine Avenue, no physical alteration of the expressway is proposed other than the pavement marking and signage needed to accommodate the HOT 3+ use. Separate projects, independent of the I-290 Selected Alternative, will

address the overhead highway bridges from east of Cicero Avenue to Racine Avenue, and are not included in this ROD.

In the 13-mile Project Corridor, 46 out of 63 eligible noise barriers are likely to be built. These 46 barriers were found to be reasonable, feasible and were approved by a majority of benefitted receptor stakeholders in the viewpoints solicitation process for noise abatement. See Section 7.0, Measures to Minimize Harm, for further information on consideration of noise barriers.

4.0 Purpose and Need

Five principal needs or need points were identified through technical analysis and through stakeholder and public input.

Regional and Local Travel: This need point addresses the identified need to improve mobility, or the movement of people and goods, within the region and the Study Area. Current daily traffic volumes far exceed the existing ideal capacity in the corridor, which negatively affect local and regional travel.

Access to Employment: Traffic congestion on I-290 and the major arterial roads in the Study Area, and the inability to adequately accommodate additional traffic, limit the effectiveness of these transportation facilities to serve local and regional employment areas. These conditions affect the traditional commute (i.e., travelers heading inbound to Chicago during the morning peak period and outbound from Chicago in the evening) and the reverse commute (travelers heading outbound in the morning peak period and inbound in the evening peak), along with other commuter travel markets that utilize this corridor. Traffic congestion on I-290 and parallel routes also negatively impacts bus transit travel times and reliability, the ability to make modal connections, and access to transit by automobile.

Safety for All Users: Within the western part of the Study Area from I-294 to Kostner Avenue (including the six-lane section between 25th Avenue and Austin Boulevard), I-290 experiences crash rates that are 24 to 70 percent higher than comparable Chicago area freeways. Crashes in the eight-lane section from Kostner Avenue to Racine Avenue in the eastern part of the Study Area were also higher than other comparable freeways, but 21 percent lower than the western section of I-290. High crash rate locations were primarily associated with the mainline capacity bottleneck loations and the left-hand ramps at Austin Boulevard and Harlem Avenue.

Modal Connections and Opportunities: Use of the existing transit facilities within the Study Area is higher than for the region as a whole; however, these transit facilities do not operate at full capacity, and facility deficiencies in the corridor inhibit access to transit facilities and hamper optimum provision of transit services. Pedestrian and bicycle access is also constrained within the Study Area. Several opportunities for improving transit facilities and services in the Study Area were identified, and the I-290

Study has been coordinated with the transit agencies for the purpose of accommodating future transit improvements within the footprint of this proposed project.

Transportation Facility Deficiencies: The existing facility was designed and constructed in the 1950s according to the design standards at the time. Since then, design standards have evolved to provide optimal safety and operational configurations. The existing pavement and bridges are now more than 50 years old, exceeding their typical service life (i.e., approximately 30 years for pavement and 50 years for bridges) and is in need of modernization. Several facility deficiencies have been identified related to: 1) pavement and structure conditions; 2) design features; 3) pedestrian, bicycle, and transit facilities; and 4) the existing drainage system and pavement flooding.

5.0 Alternatives Considered

5.1 Development and Evaluation of Alternatives

The development and evaluation of the alternatives was an iterative process guided by extensive stakeholder involvement as described in Section 4.0 of the FEIS, combined with technical analysis and environmental impact avoidance/minimization efforts using field surveyed resource data and impact modeling. The alternatives development and evaluation process in Section 2.0 of the FEIS concluded with the identification of a range of alternatives to be considered (including a No Build Alternative). The process leading up to the selection of the FEIS alternatives consisted of three rounds of identification, evaluation, and refinement that initially considered a wide range of suggested alternatives, evaluated single mode alternatives, and then assembled and evaluated combination mode alternatives that resulted in the selection of four build alternatives carried forward for further refinement and analysis in Section 3.0 of the FEIS. These steps are summarized here:

Initial Range of Stakeholder Suggestions: Suggestions for alternatives for the I-290 Study were actively solicited from project stakeholders and the public through public meetings, Corridor Advisory Group/Task Force (CAG/TF) meetings, stakeholder meetings, and public comments. A total of 570 suggestions were submitted regarding alternatives.

Round 1 – Single Mode Alternatives Identification and Evaluation: After condensing the 570 alternatives into 33 concept categories, they were prescreened to identify "single mode" alternative concepts to be evaluated independently in Round 1. 21 single mode transit, highway, and arterial alternatives were developed and evaluated in Round 1: eleven I-290 expressway alternatives, nine transit alternatives, and one arterial highway widening alternative. The arterial highway widening alternative was fatally flawed due to limited available right-of-way and potential impacts. The remaining 20 alternatives were evaluated with respect to a range of transportation performance criteria. It was determined that the expressway alternatives provide the best overall performance and stand-alone transit alternatives did not improve I-290 performance, but have other

benefits. The Round 1 results were used to inform the next round of alternatives development.

Round 2 – Combination Mode Alternatives Identification and Evaluation: Based on the results of the Round 1 single mode alternative evaluation, ten combination mode alternatives were assembled for evaluation in Round 2. The approach was to test the overall performance of the expressway modes in combination with additional benefits of transit modes. The Round 2 alternatives tested included two transit modes, Express Bus service (EXP) or a combination EXP and High Capacity Transit (HCT) extension to Mannheim Road, in combination with the following expressway modes: General Purpose (GP) Lanes (all lanes non-tolled GP lanes); High Occupancy Vehicle (HOV) 2+ (one HOV lane and three GP lanes in each direction); Toll (all lanes tolled); High Occupancy Toll (HOT) 3+ (one HOT lane and three GP lanes in each direction); and an expressway alternative that paired Toll Lanes and HOT 3+. During the evaluation of the initial ten combination mode alternatives, the CAG identified two additional combination mode alternatives that combined transit and expressway management strategies, but without a lane addition in the existing six-lane section of I-290, for a total of 12 combination mode alternatives evaluated in Round 2.

The alternatives were scored against the project purpose and need two ways, using "rank" scoring (where each need point category contributes equally to the overall score) and "ratio" scoring (weighting for each measure based on the relative performance differences between the alternatives). Based on the results of the Round 2 evaluation, the top four performing alternatives were further developed and refined in Round 3, and were considered in detail in the FEIS (Section 5.2).

Round 3 – Further Definition and Refinement of Build Alternatives: Based on the results of the Round 2 evaluation, the Study Area was formally extended in Round 3 to include an additional 4 miles east to Racine Avenue (Section 2.5.1 of the FEIS) to connect to the improvements being constructed at the Jane Byrne Interchange. Interchange type and expressway access studies were layered in with the further design refinement and detailed performance and environmental evaluation of alternatives in Round 3. The Round 3 evaluation introduced environmental and cost factors, and included both rank and ratio scoring.

Full reconstruction of the expressway from west of Mannheim Road to east of Cicero Avenue is required to accommodate mainline capacity and interchange improvements. Based on condition assessment and operational analysis of the build alternatives, no new expressway reconstruction or capacity improvements were identified for the eight-lane section between east of Cicero Avenue and Racine Avenue; at most, only a restriping and appropriate signage of the eight-lane section is required to implement a build alternative. As such, reconstruction of the eight-lane section east of Cicero Avenue is not proposed; however, the condition of the overhead bridges in this section is being addressed as part of a separate study.

Other Refinements and Considerations: Based on the safety and right-of-way, and in consideration of CTA's Blue Line Forest Park Branch Feasibility/Vision Study findings, the proposed expressway design was configured to utilize a 10-foot strip of available CTA Blue Line right-of-way (between Circle Avenue and Austin Boulevard) to provide wider shoulders for improved expressway safety performance in this area. Improved freight railroad clearance over the CSX Railroad, to a minimum of 21-feet 9-inches, was achieved via reduced cross-road bridge depths and minor track lowering. Intelligent Transportation System components were recommended to facilitate lane management and to further improve safety.

CTA Blue Line Vision Study: The CTA Blue Line Forest Park Branch Feasibility/Vision Study was initiated in 2013 by the CTA, and was performed in parallel with the I-290 EIS Study. Results of the Blue Line Vision Study were incorporated into the I-290 EIS. It is noted that the Vision Study is not an Environmental Impact Statement, nor is it part of a federal project development process. The findings of the Vision Study include the need for reconstruction of the entire Forest Park Branch. Other key recommendations include:

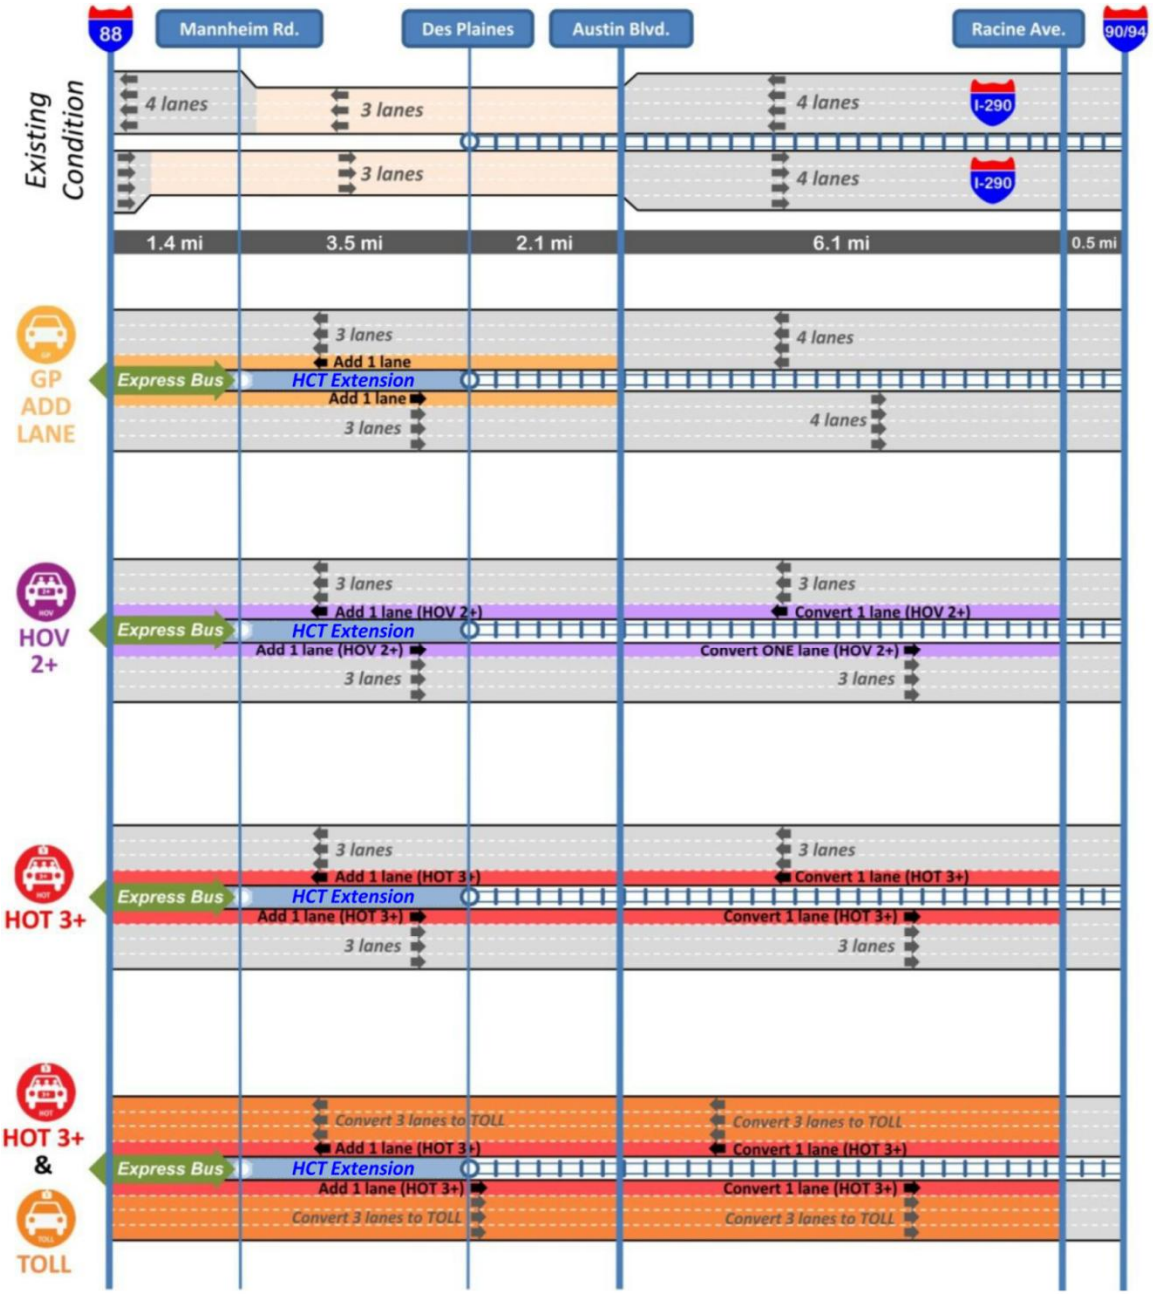
- Maintain existing entrance locations;
- Remove stations closed in 1970s;
- Improve infrastructure to a state of good repair;
- No third track or express service;
- Improve the terminal site at Forest Park;
- Maintain existing service; and
- Work with IDOT on Project Corridor improvements through design, construction, and funding.

In the short term, CTA would continue to perform interim work to address slow zones and other maintenance items.

5.2 Alternatives Considered in Detail

Four build alternatives evaluated in the FEIS included:

- **GP & EXP & HCT** (also referred to herein as GP Lane), consisting of adding one general purpose lane[1] in each direction between 25th Avenue and Austin Boulevard, and includes provisions for Express Bus (EXP) and High Capacity Transit (HCT);
- **HOV 2+ & EXP & HCT** (also referred to herein as HOV 2+), consisting of adding one High Occupancy Vehicle (HOV) 2+ (two or more occupants required for use) lane in



[1] "General purpose lanes (also referred to as "mixed-use" or "mixed-flow" lanes) are those where use is allowed by all vehicles (except certain small motorized vehicles, bicycles, and pedestrians on limited-access highways), without restriction on number of occupants or imposition of a toll. All lanes on I-290 are currently general purpose.

each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction east of Austin Boulevard to HOV use, and provisions for EXP and HCT;

- **HOT 3+ & EXP & HCT** (also referred to herein as HOT 3+), consisting of adding one High Occupancy Toll lane (HOT) 3+ (free for vehicle with three or more occupants, or one/two occupants per vehicle paying a toll) in each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction east of Austin Boulevard to HOT 3+ use, and provisions for EXP and HCT;
- **HOT 3+ & TOLL & EXP & HCT** (also referred to herein as HOT 3+ & TOLL), consisting of adding one HOT 3+ lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction and east of Austin Boulevard to HOT 3+ use, conversion of the remaining general purpose lanes to toll lanes (users of these lanes paying a toll), and provisions for EXP and HCT; and
- The **No Build Alternative** was also carried forward to provide a baseline of comparison of travel benefits, as well as environmental impacts. This alternative consisted of planned improvements to existing roadway and transit facilities in the Study Area that are expected to be constructed by the design year (2040) with the exclusion of major improvements to I-290 or the CTA Forest Park Branch. The transportation conditions assumed to exist under the No Build Alternative included the existing transportation network plus major capital projects (excluding major capital projects in the Study Area) currently in the metropolitan planning organization's 2040 fiscally constrained metropolitan transportation plan referenced in Section 1.1 of the FEIS. The environmental conditions that would exist under the No Build Alternative were generally consistent with the existing conditions as described in Section 3.0 of the FEIS, except to the extent that those existing conditions would be affected by other actions (e.g., other transportation or development projects) as described in Section 3.15 of the FEIS. The No Build Alternative would not satisfy the project's Purpose and Need.

Figure 3 shows a concept for each of the four build alternatives, along with the existing condition (No Build Alternative).

Figure 3. Alternatives Carried Forward in the FEIS

6.0 Basis for Selecting Alternative HOT 3+ & EXP & HCT

6.1 Summary of Selected Alternative Evaluation

The four build alternatives have identical footprints. Therefore, they are very similar to one another; the differences between the alternatives are related to travel performance and social and economic and environmental impacts due to the manner in which traffic would be managed, and the differences in traffic volumes and patterns resulting from this management. Given that the project is located in a developed urban setting, the proposed improvements are almost entirely contained within existing I-290 right-of-way. The only exceptions are 3.322 acres of additional right-of-way (ownership) and permanent easement required at five interchanges or cross-roads proposed for reconstruction and 2.650 acres of right-of-way (ownership) for a 10-foot-wide strip of right-of-way from the CTA Blue Line. The build alternatives result in no residential or commercial displacements. In addition, the Austin Boulevard and Harlem Avenue interchange ramps would retain their current cross-road connection locations centered over the expressway (although converted to right hand on- and off-ramps) in response to community concerns.

All four build alternative improve safety for motorists and pedestrians. Primary safety improvements include elimination of the expressway lane drops (westbound at Austin Boulevard and eastbound at 25th Avenue), which will help reduce congestion related rear-end and side-swipe crashes that are prevalent with lane drops. As stated previously, the left-hand ramps at the Austin Boulevard and Harlem Avenue interchanges are proposed to be converted to conventional right-hand ramp exits and entrances, which are consistent with driver expectations and with all other ramps in the corridor. The interchanges and cross roads would also be designed to modern standards, including improved truck turning radii, improved vehicle storage, wider sidewalks, additional crosswalks, Americans with Disabilities Act (ADA) accommodations, pedestrian plaza areas, modern pedestrian countdown signals, and pedestrian refuge islands in between the ramps at the Austin Boulevard and Harlem Avenue interchanges.

All four build alternatives improve access to transit and non-motorized travel. This includes wider sidewalks on all cross bridges in the Reconstruction Section, including additional width for sidewalks serving CTA Blue Line stations. Increased pedestrian plaza space at CTA Blue Line station entrances to provide space for bicycle parking, bus passengers, and bus passenger shelters. Relocation of some bus stops will provide shorter and more convenient connections, and access to CTA Blue Line stations in the nine-mile reconstructed section of I-290 would be entirely ADA accessible, which is currently not the case in much of the corridor.

With regard to environmental resources, the four build alternatives have no impacts to wetlands, wildlife, and agricultural resources. The four build alternatives each result in the same 12.94 acre-feet net decrease in floodplain fill volume, and water quality standards would continue to be met. There would be no direct use of adjacent Section 4(f) resources required by the build alternatives except for a *de minimis* impact to 0.031 acre of public parkland in the Village of Forest Park and a temporary use of 0.137 acre of parkland in the Village of Forest Park. There is a Section 4(f) exception under 23 CFR 774.13(g) of 2.74 acres for enhancements at Columbus Park. There are no distinguishing differences between the build alternatives with respect to potential uses of Section 4(f) resources.

Environmentally Preferred Alternative: In an overall evaluation of build alternatives to determine which causes the least damage to the biological and physical environment, the HOT 3+ Alternative is identified as the environmentally preferred alternative. Since the biological and physical impacts are identical among the four build alternatives in most areas of interest examined in the FEIS, there is little distinction on which to base preference of one build alternative over another for environmental reasons. However, identification of HOT 3+ as the environmentally preferred alternative is based on the following factors as compared to the other three build alternatives:

- The HOT 3+ Alternative provides the best overall improvements in air quality; and
- The HOT 3+ Alternative provides the best overall travel performance with respect to environmental justice (EJ) communities. The HOT 3+ lane provides additional travel choices (car-pooling), diverts traffic off arterials within EJ communities, and provides a reliable travel option for transit users.

Each of the four build alternatives would satisfy the Project Purpose and Need. However, the level of overall travel performance and the economic benefits vary between each of these alternatives. Since the physical footprint on the land by each of the build alternatives is primarily confined within the existing I-290 right-of-way and is the same for the four build alternatives, environmental mitigation would be identical for each of the alternatives.

6.1.1 Social/Economic Impacts

The Project Corridor traverses highly developed areas of the Chicago metropolitan region and is almost fully built-out with little unused, underdeveloped urban land. The predominant racial groups in the Project Corridor are Black at 58.1 percent of the total population, Whites at 29.8 percent, and 9.7 percent of the population that consider themselves Hispanic or Latino. Median household incomes for all core communities are higher than the poverty guidelines. Westchester and Elmhurst had the lowest percentages of persons living below the poverty line, while communities with the highest percentages below poverty were generally found on the eastern portion of the corridor. Chicago has the highest percentage of persons below the poverty line at 21.4 percent.

Year 2040 No Build and Build socio-economic forecasts were prepared as part of the I-290 Study based on the change in highway and transit accessibility. The I-290 Study

Area population and employment forecasts for the No Build versus Build Scenario indicate a less than one percent change due to the existing built-out urban conditions in the Study Area and that the proposed project reflects improvements to an existing facility that already provides accessibility to the Study Area. As shown in Table 1, all of the build alternatives would result in long-term benefits from improved access to and from I-290 and annual productivity savings in 2040 that would range from $86 to $152 Million.[2] The build alternatives would not change land use patterns and comply with local and regional comprehensive plans. All existing access points to I-290 would be maintained. 5.972 acres of right-of-way (ownership) and permanent easement would be required, although there would be no resulting displacements of residences or businesses.

Table 1. Distinguishing Socioeconomic Impacts

Resource	Analysis Level	No Build Alternative	Build Alternatives			
			GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
Traffic diversion to local roads (VMT)	Quantitative	--	-24,560	+6,944	-8,853	+147,834
Average change in travel time to job destinations from the 2040 No Build Alternative, EJ Communities	Quantitative	--	-1 to -3 minutes	0 to -9 minutes	-1 to -10 minutes	-1 to -9 minutes
Average change in travel time to job destinations from the 2040 No Build Alternative, non-EJ Communities	Quantitative	--	-2 minutes	-2 to -5 minutes	-2 to -5 minutes	-4 to -6 minutes
Construction-related jobs created[1]	Quantitative	--	18,904	18,904	18,980	18,980
Productivity (based on travel time savings)	Quantitative	--	+$1.6 B	+$1.6 B	+$2.7 B	+$2.9 B

[1] NCHRP 08-36, Task 103 - Mining Recovery Act Data for Opportunities to Improve the State of Practice for Overall Economic Impact Analysis of Transportation Investments, Cambridge Systematics & Economic Development Research Group, 2012. 10.55 jobs/$1M construction cost in 2010 adjusted to 9.82 jobs/$1M construction cost for 2015 using CPI. 2015 cost estimates used as basis for estimating direct construction jobs.

[2] Productivity savings is travel time savings multiplied by the time value of money. Assumes $24 per hour value of time per the NCHRP Report 456 Guidebook for Assessing the Social and Economic Effects of Transportation Projects.

Environmental Justice: No substantial differences in transportation access were found with any of the build alternatives with respect to EJ communities, as compared to non-EJ communities, and all build alternatives had benefits in job accessibility and non-motorized and transit access for EJ communities that were similar to non-EJ communities. Of the build alternatives, the HOT 3+ & TOLL Alternative impacted the 2040 arterial traffic more than the No Build Alternative, while the other three build alternatives showed more positive effects. Environmental effects, such as those related to air, noise, and social and economic resources (including construction impacts), were similar for EJ and non-EJ communities, and no residences or businesses in either EJ or non-EJ communities are proposed to be displaced by any of the build alternatives. Public involvement was encouraged by the participation of representatives of EJ communities in the project's Corridor Advisory Group (CAG) study group, as well as traditional and nontraditional means of engaging the public in participation at public and community meetings. Though there would be impacts (i.e., noise and construction impacts in particular) to EJ and non-EJ communities along the Study Area, upon implementation of the planned mitigation, as described in Section 7.0 and the FEIS, and coordinated with each community, the impacts would not be disproportionately high and adverse to EJ communities.

6.1.2 Special Lands

The proposed project would require small areas of new right-of-way from two parks in the Village of Forest Park to accommodate pedestrian and bicycle access improvements requested by the Village and the temporary use of a third park during construction. The proposed improvements would occur as follows:

- Veterans Park (at 631 Circle Avenue): 0.027 acre (temporary)/0.018 acre (permanent) to provide for a wider, 12-foot wide sidewalk and a new on-street 6-foot wide bicycle lane along Circle Avenue, and a new sidewalk on the park's western boundary to connect the park with the proposed shared-use path (requested by the Village).
- The Dog Park (at 632 Circle Avenue): 0.020 acre (temporary)/0.013 acre (permanent) to provide for a wider, 10-foot wide sidewalk along Circle Avenue and a new on-street 6-foot wide bicycle lane (requested by the Village).
- Park District of Forest Park (Recreational Center-Roos property): 0.091 acre (temporary) to provide work space for installing a 5-foot wide sidewalk on the west side of Circle Avenue south of I-290.

As stated in Section 3.12.3 of the FEIS, FHWA has issued a *de minimis* impact finding for Veterans Park, the Dog Park, and the Roos Property based on the minimization measures proposed and written concurrence from the Officials with Jurisdiction (OWJs) that there is not an adverse effect to the features, attributes, and activities that make the properties eligible for 4(f) protection. The project would not adversely impact the long-term use, function, or development of these parks.

At Columbus Park, the project proposes to improve bicycle and pedestrian access at the southwest corner of Columbus Park near Austin Boulevard by completing a trail

connection between the proposed east-west shared-use path extending from west of Austin Boulevard to the existing Columbus Park trail situated along its southern edge. This access improvement would involve a Section 4(f) exception of approximately 1.03 acres in the southwestern corner of the park to allow construction of a 450-foot long shared-use path. Ultimately, this connection would effectively extend direct access to the Illinois Prairie Path into the City of Chicago, and in combination with the proposed shared-use trail, would provide an additional 2.5 miles of continuous nonmotorized access between DesPlaines Avenue and Central Avenue. Landscape enhancements would also be undertaken along the eastern half of the park's southern boundary involving a Section 4(f) exception of 1.71 acres. The Chicago Park District and SHPO concurred that these improvements meet the requirements for Section 4(f) exception under 23 CFR 774.13(g).

6.1.3 Historic Properties

FHWA's Section 106 effect finding considered that the Preferred Alternative would have no effect to six historic properties and no adverse effect to 17 historic properties in the Area of Potential Effects (APE). No direct physical impacts to 22 of the 23 historic properties would occur as a result of the Preferred Alternative because the proposed improvements generally fit within existing right-of-way, outside of National Register of Historic Places (NRHP) boundaries. As described above, project activity at the request of the Chicago Park District is proposed within the National Historic Landmark (NHL) boundary of Columbus Park, but the Section 4(f) exception and proposed improvements would have no adverse effect to the property. Additionally, no indirect effects to historic properties would occur because traffic noise and visual project components would not adversely diminish their integrity or alter the characteristics qualifying these properties for the NRHP. SHPO concurred with the Section 106 finding of no adverse effect on May 25, 2017. Therefore, FHWA made an overall project finding of no adverse effect.

6.1.4 Visual Resources

In those sections to be reconstructed along the Project Corridor, an effort will be made to create a consistent corridor aesthetic. While the final design is yet to be completed, the general appearance of walls, noise barriers, bridge piers, and fencing is anticipated to include the textures and forms illustrated in FEIS Section 3.13.4.

The quality and character of the existing viewsheds of the Project Corridor as viewed from the adjacent land uses is a result of the original I-290 construction. Since that time, the density and quality of existing vegetation affects the ability to view one side of the corridor from the other where the right-of-way is wider and the vegetation is densest. The primary visual consequence of the build scenarios as viewed from outside the corridor would be the loss of this vegetation and the potential placement of noise barriers. To mitigate for this loss, the retaining walls and other structures would be located such that the maximum amount of green space is created between the new retaining walls and the adjacent off-corridor land uses. Where space permits, landscape plantings would be installed to restore the lost vegetation and to soften the appearance of the noise barriers, as described in FEIS Section 3.13.5.2.

6.1.5 Air Quality

Air quality analysis of the four build alternatives included pollutant burden analysis, Mobile Source Air Toxics (MSATs), and greenhouse gas (GHG) emissions. Overall, the build alternatives are expected to show minor changes (generally less than one percent better or worse) in regional pollutants, GHG emissions, and MSATs compared to the No Build Alternative, and no local impacts are currently identified. Of the four build alternatives, the HOT 3+ Alternative provided the best overall air quality benefits, with reductions in all of the air quality measures evaluated. It is noted that the differences in air quality effects of the build alternatives, while having slight differences, were not sufficiently distinguishable to be used in the scoring used to evaluate these alternatives in the FEIS.

Table 2 includes a summarization of the differing air quality impacts of the build alternatives.

Table 2. Traffic Noise and Air Quality Impacts

Resource	Unit of Measure	No Build Alternative	Build Alternatives			
			GP Add Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
Traffic Noise						
Receptors approaching, meeting or exceeding noise abatement criteria	Each	227	230	228	229	220
Pollutant Burden (annual burden – tons)[1]						
VOC (Hydrocarbon)	Tons	1,270	+0.10%	-0.01%	-0.14%	-0.02%
NO_X	Quantitative	2,776	+0.21%	-0.12%	-0.07%	-0.60%
CO	Quantitative	23,708	+0.73%	-0.51%	-0.34%	-0.35%
PM_{10}	Quantitative	1,813	-0.06%	-0.03%	-0.31%	-0.43%
$PM_{2.5}$	Quantitative	326	+0.09%	-0.13%	-0.30%	-0.50%
Greenhouse Gas Emissions (annual burden – million tons)[1]						
CO_2e	Quantitative	10.517	+0.24%	+0.03%	-0.01%	-0.10%
MSAT (annual tons)[1]						
Acrolein	Quantitative	1.17	-0.08%	-0.07%	-0.17%	-0.62%
Benzene	Quantitative	16.55	+0.30%	-0.04%	-0.08%	+0.05%
1,3 Butadiene	Quantitative	0.07	-0.20%	-0.08%	-0.20%	-0.83%
Diesel PM	Quantitative	50.24	+0.10%	-0.13%	-0.16%	-1.11%
Formaldehyde	Quantitative	25.90	-0.07%	-0.07%	-0.17%	-0.60%
Naphthalene	Quantitative	2.19	-0.02%	-0.06%	-0.16%	-0.53%

[1] Provided as sensitivity test for informational purposes; not intended for Selected Alternative selection. Figures in green represent decreased impacts and figures in red represent increased impacts, as compared to the No Build Alternative.

6.1.6 Special Waste/Hazardous Waste Impacts

The Illinois State Geological Survey (ISGS) Preliminary Environmental Site Assessment (PESA) reports identified numerous recognized environmental condition (REC) sites, all of which have the potential for soil or groundwater contamination and could potentially pose a risk to construction activities. Thirteen (13) REC sites were identified as being within or directly adjacent to the proposed right-of-way acquisitions. These REC sites may require further evaluation including testing (preliminary site investigation [PSI]). The determination whether further assessment is necessary will be evaluated as the proposed project progresses and detailed design becomes available. The decision generally depends on the nature of the REC, its proximity to the planned construction activities, and its potential impact to the proposed project. There is no differentiation in special waste/hazardous waste impacts between the build alternatives.

6.1.7 Natural Resources Impacts

The build alternatives are located predominantly in developed areas associated with existing roadways. No impacts to forest preserves or state-designated lands are proposed, and all of the four build alternatives would result in the same impacts to habitat. Overall, project-related impacts to wildlife associated with the build alternatives would be minimal, and would be identical among these alternatives.

6.1.8 Traffic Noise Impacts

Under existing conditions, 220 of the 288 noise receptors identified currently approach or exceed the Noise Abatement Criteria (NAC).[3]

For 2040 conditions, the slight difference in traffic noise impacts among the build alternatives correlates to their traffic volume differences. The GP Lane Alternative had the greatest amount of traffic noise impacts among the four build alternatives (230 receptors above the NAC), followed by the HOT 3+ Alternative (229) the HOV 2+ Alternative (228), and the No Build Alternative (227). The HOT 3+ & TOLL Alternative was found to have the least amount of traffic noise impacts among the build alternatives (220), and this alternative also has the lowest projected traffic volumes of the four build alternatives. It is noted that the differences in noise impacts of the build alternatives were used in the scoring used to evaluate these alternatives in the FEIS. Table 2 includes a summarization of the differing noise impacts of the build alternatives.

6.1.9 Stakeholder and Agency Input

IDOT's Context Sensitive Solutions (CSS) process was implemented as part of the Environmental Impact Statement (EIS) study beginning with project scoping and development of the project and was effective in guiding the project toward consensus on a preferred alternative. The CSS process for the EIS was initiated in October 2009 with the initial assembly of the project CAG. The CAG consisted of representatives from each

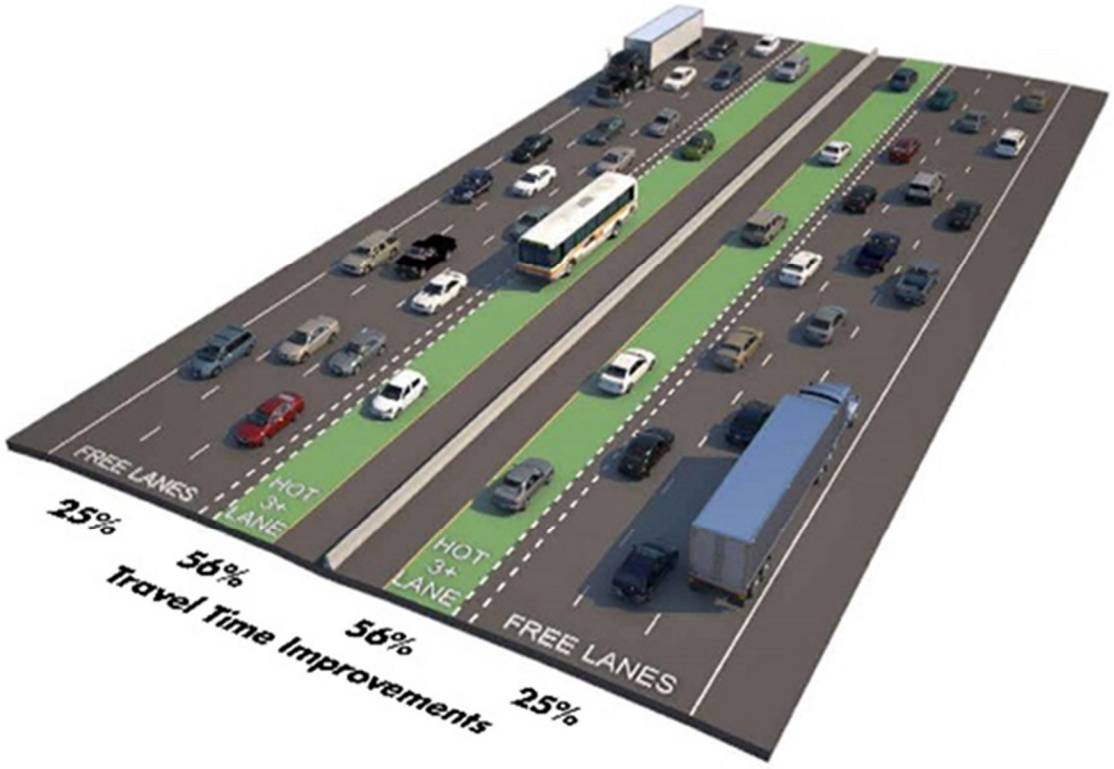
[3] Per IDOT policy, traffic noise impacts are identified only for the future build condition, not for the existing or future No Build condition. Comparisons of the existing and future No Build noise levels to the NAC are for comparison purposes only.

corridor community, transportation agencies, and interest groups and was open to the general public. Twenty-two (22) meetings were held with this group during the NEPA process and at study milestones. The CAG participants played a key role in the identification, development, and refinement of build alternatives, including recommendation of a preferred alternative.

Parallel to the CAG process, individual community, agency, and other stakeholder meetings were held to present information, listen to stakeholder concerns and needs, and discuss and refine ideas. The stakeholders for this project can be categorized broadly as federal and state regulatory agencies; state, county, and municipal officials; interest groups and organizations; other entities, such as utilities, public transit agencies, railroads, and businesses; and private citizens. Stakeholder identification and communication is described in more detail in Section 4.0 of the FEIS and the Stakeholder Involvement Plan.[4]

Six NEPA/404 Merger meetings were held, and more than 150 meetings were held individually with project stakeholders. A series of 10 Transit Working Group meetings were conducted to guide the overall corridor-level development of the alternatives, which included representatives from IDOT, CTA, Illinois Tollway, Pace, Metra, and RTA.

A series of three public meetings and four town hall meetings were also held throughout the project development process. These meetings were supplemented with various other speaking engagements at the request of stakeholders. Two public hearings on the I-290 DEIS were held at different locations on consecutive days (Chicago on January 25 and Maywood on January 26, 2017) to present the DEIS, to answer questions, and to receive public comments. There were 281 attendees at the two hearing locations combined, 17 attendees who participated in the question-and-answer sessions at the hearings, and a total of approximately 332 unique comments within 124 overall comments received during the DEIS comment period.



A suite of outreach tools was used to reach all stakeholders, with an emphasis on EJ communities. These tools included a project website (www.eisenhowerexpressway.com), newsletters, e-mail blasts to a 3,000-count stakeholder mailing list, billboards, content prepared for village websites, and media releases. As a result of this collective outreach and community involvement, more than 1,700 public comments were received and considered from October 2009 to April 2017. The culmination of this robust stakeholder outreach program has resulted in a project that broadly reflects community and stakeholder values in the Project Corridor.

[4] Stakeholder Involvement Plan, Version 5 (2016) http://www.eisenhowerexpressway.com/pdfs/i290_stakeholderinvolvementplan_v5.pdf.

6.2 Conclusion

In considering the key factors identified with respect to meeting project goals and objectives, travel performance, and social/economic and environmental impacts, the HOT 3+ Alternative provides the best balance of benefits, avoids social/economic and environmental impacts, and provides travel benefits to EJ communities. The HOT 3+ Alternative results in a 25 percent travel time savings in the GP lanes and a 56 percent travel time saving for users of the managed lane (Figure 4).

Figure 4. Selected Alternative Travel Time Improvement

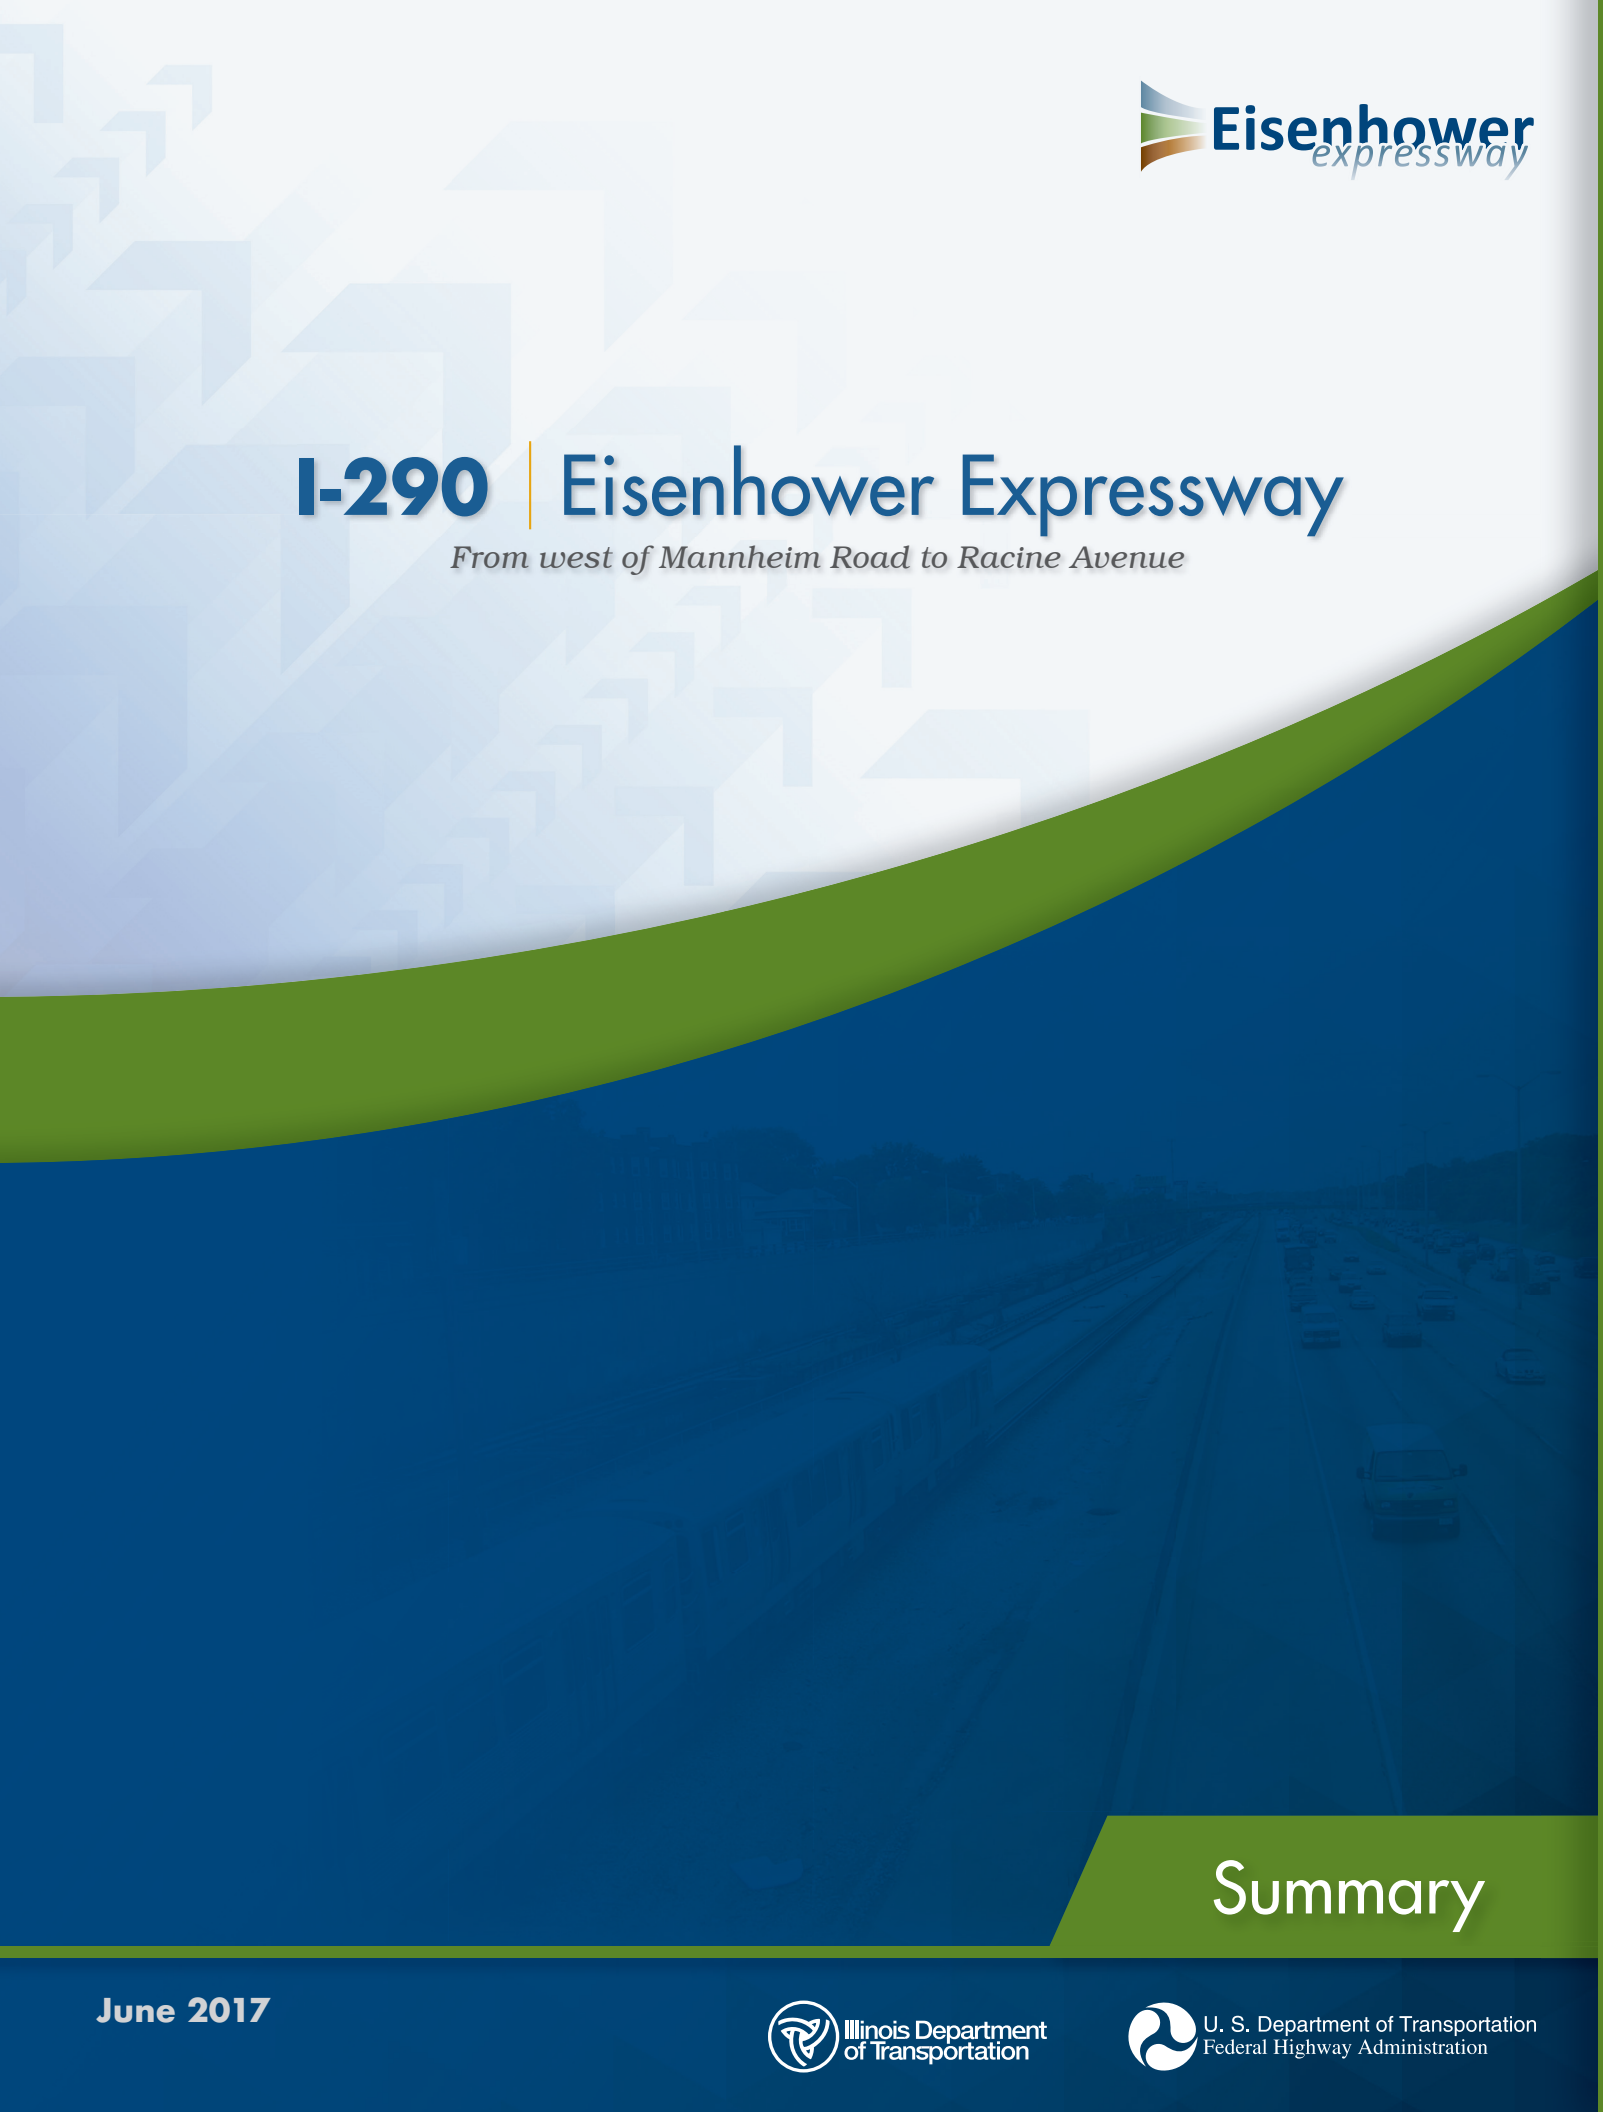
7.0 Measures to Minimize Harm

Mitigation and abatement measures would be completed in accordance with the policies and procedures of FHWA and IDOT and the requirements of the appropriate federal and state resource agencies. Section 3.19 of the FEIS provides a detailed summary of mitigation commitments. Due to the limited amount of right-of-way required and that there are no displacements for any of the build alternatives, few mitigation measures are required. The primary mitigation measures identified are:

- Traffic Noise. Forty-six (46) noise walls, which would benefit 4,027 receptors, were determined reasonable and feasible after completing the viewpoints solicitation. Future coordination in the design phase may result in reopening the viewpoints solicitation process where warranted by changes in the number/location of benefited stakeholders, the benefited stakeholders' opinions, or noise wall technology. The noise barriers likely to be constructed are shown in the Section 3.0 Map Set of the FEIS.
- Tree Mitigation. Impacts to trees would be minimized with installation of construction fencing and exclusion zones to reduce compaction of roots and soil. Mitigation for trees removed would be guided by IDOT's Preservation and Replacement of Trees (IDOT, 2002) policy and Chapter 59 ("Landscape Design") of the Bureau of Design and Environment (BDE) Manual (IDOT, 2014).

  A landscaping plan would be developed during the design phase that would identify areas where trees, shrubs, and grasses would be planted on highway side slopes, on back slopes, and in the median, except where clear vision needs to be maintained at highway entrances and exits, intersections, and median openings.
- Visual Resources. Mitigation for visual impacts may include implementation of context sensitive design, which involves public input, and landscape improvements for the replacement of existing landscaping, creation of new landscape areas, public input in the use of alternative materials and design of noise barriers, and installation of containerized plantings located on the cross-road overpass bridges.

8.0 Approval



Based on the analysis and evaluation contained in the FEIS and after careful consideration of all the social, economic, and environmental factors described in the FEIS with input received from other agencies, organizations, and the public, it is the decision of the FHWA to approve HOT 3+ & EXP & HCT as the Selected Alternative.

Eisenhower expressway

I-290 | Eisenhower Expressway

From west of Mannheim Road to Racine Avenue

SUMMARY

Summary

June 2017

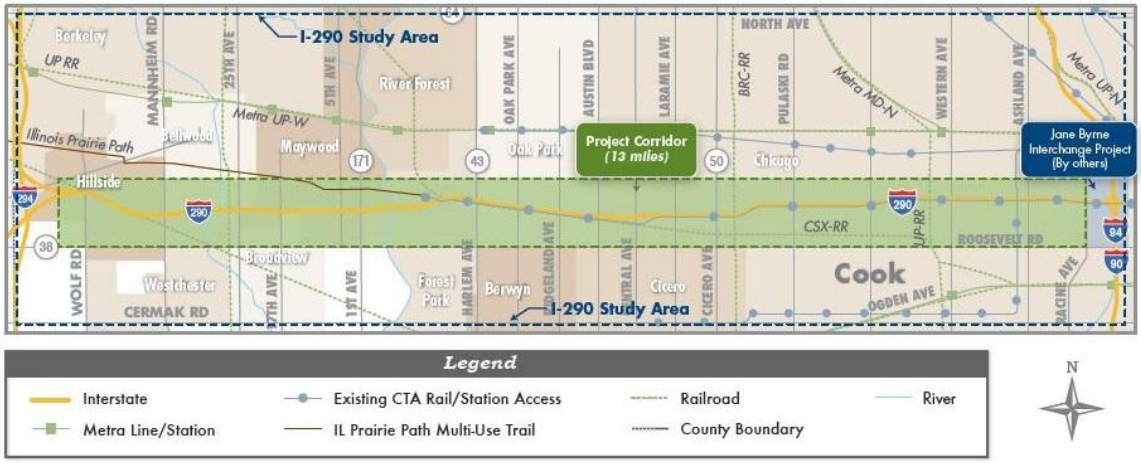
Illinois Department of Transportation

U. S. Department of Transportation
Federal Highway Administration

S.0 Summary

Since publication of the Draft Environmental Impact Statement (DEIS), the following substantive changes to this section have been made:

- Updated Section S.4 with a more detailed description of Round 2 alternatives advanced into Round 3;
- Updated Sections S.5 and S.6 to describe the results of the Section 106 effects findings for historic properties within the Area of Potential Effects (APE); and
- Updated Sections S.5 and S.6 to confirm receipt of Officials with Jurisdiction (OWJ) concurrence to *de minimis* impact and Section 4(f) exception findings within Village of Forest Park parklands and Columbus Park.



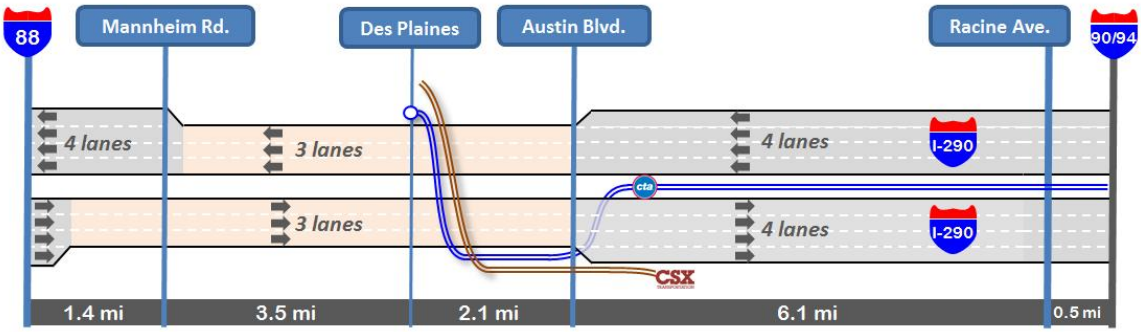
S.1 Project Description

The purpose of this proposed project is to provide an improved transportation facility along the Interstate 290 (I-290) Eisenhower Expressway multimodal corridor. Five purpose and need points were identified for improving transportation along this facility: 1) mobility for regional and local travel; 2) access to employment; 3) safety; 4) modal connections and opportunities; and 5) transportation facility deficiencies. The lead agencies developing the project are Illinois Department of Transportation (IDOT) and Federal Highway Administration (FHWA). Cooperating agencies include Federal Railroad Administration and Federal Transit Administration.

Project Background and Study Area: The Eisenhower Expressway (I-290), originally constructed as the Congress Expressway, was one of the first multimodal facilities in the United States. Opened to traffic in sections beginning in the mid to late 1950s, this facility was designed and constructed according to early standards that were newly created for the interstate highway system. A Chicago Transit Authority (CTA) rapid transit line, the Forest Park Branch (Blue Line), and a freight railroad (CSX) run parallel and adjacent to I-290 for a portion of its length from Forest Park to Chicago.

The Study Area is centered along I-290 in Cook County, extending from west of Mannheim Road to Racine Avenue. The northern boundary of the Study Area is North Avenue, and the southern boundary is Cermak Road, an area of approximately 55 square miles. The Study Area, shown in Figure S-1, includes adjacent transit and freight railroads, interchanges, cross streets, and other parallel and crossing features that are within or in close proximity to I-290.

Figure S-1. I-290 Study Area



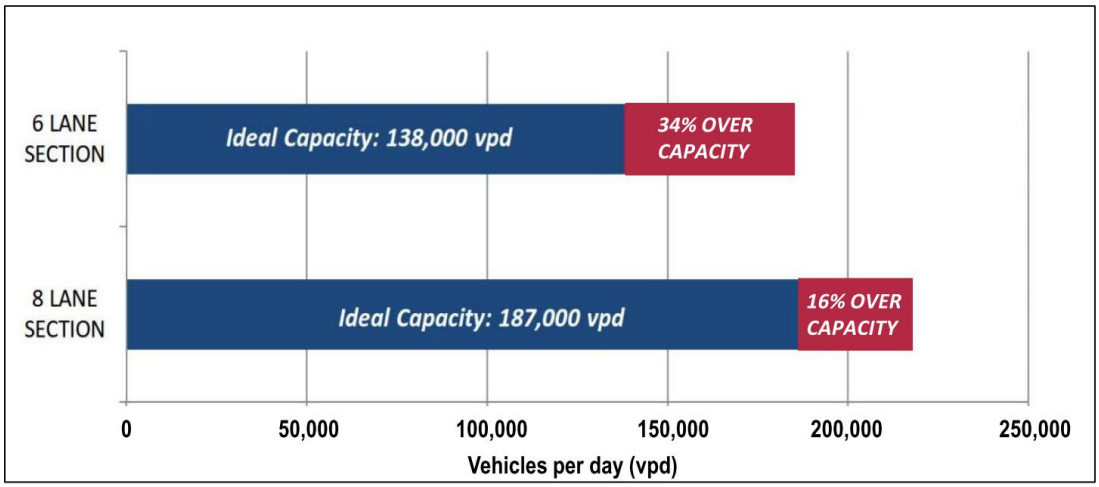
Source: WSP Parsons Brinckerhoff, 2016

The logical termini for the I-290 Study are identified as I-290 west of Mannheim Road (where there are currently four lanes in each direction) to Racine Avenue (adjacent to the Jane Byrne Interchange project which began construction in 2013).

In the sections west of Mannheim Road and east of Austin Boulevard, I-290 has four lanes in each direction; and between Mannheim Road and Austin Boulevard, I-290 has three lanes in each direction, as shown in Figure S-2. This reduction in lanes and lane imbalance has been a long-standing source of safety, operational, and capacity concerns.

Figure S-2. I-290 Existing Configuration

Source: WSP Parsons Brinckerhoff, 2016.



The I-290 Eisenhower Expressway is identified as a fiscally constrained major capital project in the region's metropolitan transportation plan adopted by the Metropolitan Planning Organization (MPO) Policy Committee, which is the designated MPO for the northeast Illinois region.

S.2 Purpose of and Need for Action

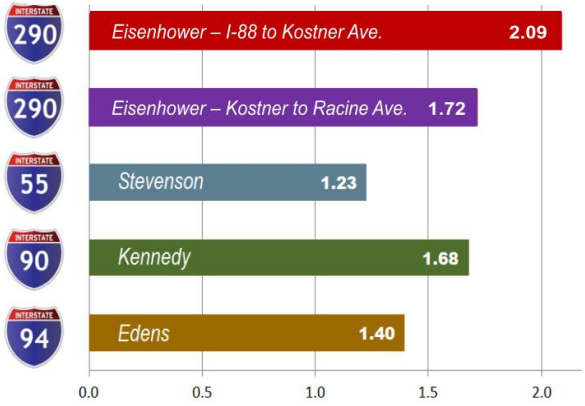
Five principal needs or need points were identified through technical analysis and through stakeholder and public input.

Regional and Local Travel: This need point addresses the identified need to improve mobility, or the movement of people and goods, within the region and the Study Area. Existing mainline bottlenecks and daily traffic volumes far exceed the existing ideal capacity in the corridor, which negatively affect local and regional travel. Figure S-3 shows the capacity deficiencies in the six-lane and eight-lane sections of I-290.

Figure S-3. I-290 Capacity Deficiencies[1]

Source: WSP Parsons Brinckerhoff, 2016.

Figure S-4. Existing I-290 Congestion



Access to Employment: Traffic congestion on I-290 and the major arterial roads in the Study Area and the inability to adequately accommodate additional traffic limit the effectiveness of these transportation facilities to serve local and regional employment areas (Figure S-4). These conditions affect the traditional commute (i.e., travelers heading inbound to Chicago during the morning peak period and outbound from Chicago in the evening) and the reverse commute (travelers heading outbound in the morning peak period and inbound in the evening peak), along with other commuter travel markets. Traffic congestion on I-290 and parallel routes also negatively impacts bus transit travel times and reliability, the ability to make modal connections, and access to transit by automobile.

1 "Ideal Capacity" represents maximum orderly traffic flow in vehicles per day; from 2000 Highway Capacity Manual, Exhibit 13-6, using volume at 10 percent of Average Daily Traffic at Level of Service E.

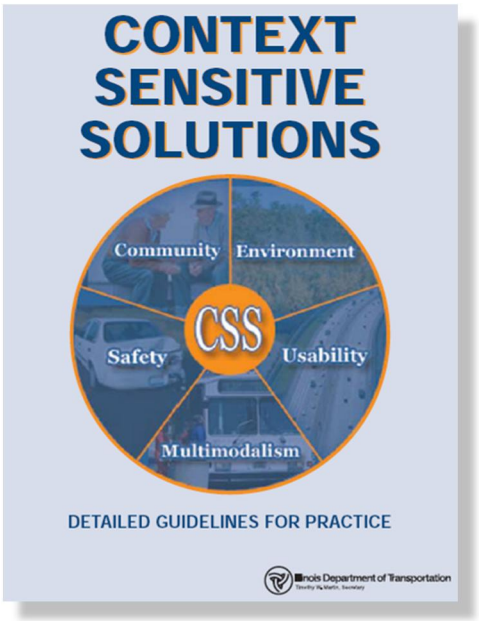
Safety for All Users: Within the western part of the Study Area from I-294/I-88 to Kostner Avenue (including the six-lane section between 25th Avenue and Austin Boulevard), I-290 experiences crash rates that are 24 to 70 percent higher than comparable Chicago area freeways. Crashes in the eight-lane section from Kostner Avenue to Racine Avenue in the eastern part of the Study Area were also higher than other comparable freeways, but 21 percent lower than the western section of I-290. High crash rate locations were primarily associated with the mainline capacity bottleneck loations and the left-hand ramps at Austin Bouelvard and Harlem Avenue. Figure S-5 provides a comparison of expressway crash rates in crashes per million vehicles per mile.

Figure S-5. Comparison of Expressway Crash Rates

Source: WSP Parsons Brinckerhoff, 2016.

Modal Connections and Opportunities: Usage of the existing transit facilities within the Study Area is higher than for the region as a whole; however, these transit facilities do not operate at full capacity, and facility deficiencies in the corridor inhibit access to transit facilities and hamper optimum provision of transit services. Pedestrian and bicycle access is also constrained within the Study Area (Figure S-6). Several opportunities for improving transit facilities and services in the Study Area have been identified, and the I-290 Study has been coordinated with the transit agencies for the purpose of accommodating future transit improvements within the footprint of this proposed project.

Figure S-6. Existing CTA Access, I-290 at Harlem Avenue



Transportation Facility Deficiencies: The existing facility was designed and constructed in the 1950s according to the design standards at the time. Since then, design standards have evolved to provide optimal safety and operational configurations. The existing pavement and bridges are now more than 50 years old, exceeding their typical service life (i.e., approximately 30 years for pavement and 50 years for bridges) and is in need of modernization. Several facility deficiencies have been identified related to: 1) pavement and structure conditions; 2) design features; 3) pedestrian, bicycle, and transit facilities; and 4) the existing drainage system and pavement flooding (Figure S-7).

Figure S-7. I-290 Flooding East of DesPlaines Avenue

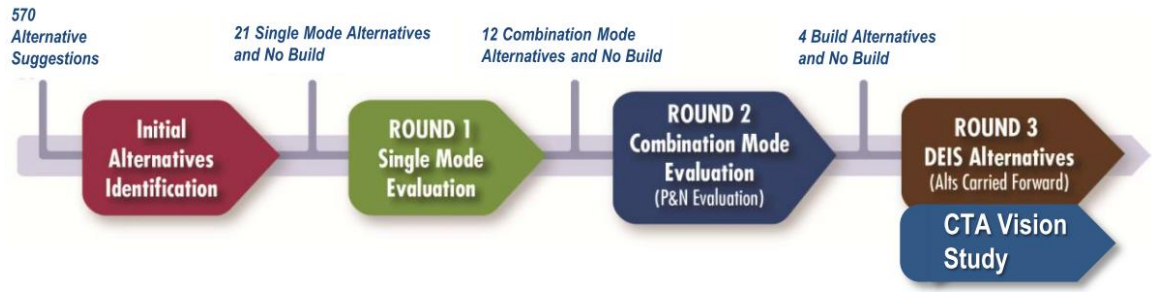
S.3 Context Sensitive Solutions and Public Outreach

IDOT's Context Sensitive Solutions (CSS) process was implemented as part of the Environmental Impact Statement (EIS) study process beginning with project scoping and development of the project and was effective in guiding the project toward consensus on a preferred alternative. The CSS process for the EIS was initiated in October 2009 with the initial assembly of the project Corridor Advisory Group (CAG). The CAG consisted of representatives from each corridor community, transportation agencies, and interest groups and was open to the general public. Twenty-two (22) meetings were held with this group along the National Environmental Policy Act (NEPA) process and at study milestones. The CAG participants played a key role in the identification, development, and refinement of build alternatives, including recommendation of a preferred alternative.

Parallel to the CAG process, individual community, agency, and other stakeholder meetings were held to present information, listen to stakeholder concerns and needs, and discuss and refine ideas. The stakeholders for this project can be categorized broadly as federal and state regulatory agencies; state, county, and municipal officials; interest groups and organizations; other entities, such as utilities, public transit agencies, railroads, and businesses; and private citizens. Stakeholder identification and

communication is described in more detail in Section 4.0 of the Final Environmental Impact Statement (FEIS) and the Stakeholder Involvement Plan.[2]

Six NEPA/404 Merger team coordination meetings were held, and more than 150 meetings were held individually with project stakeholders. A series of 10 Transit Working Group (TWG) meetings were conducted to guide the overall corridor-level development of the alternatives, which included representatives from IDOT, CTA, Illinois Tollway, Pace, Metra, and RTA.



A series of three public meetings and four town hall meetings were also held throughout the project development process. These meetings were supplemented with various other speaking engagements at the request of stakeholders. Two public hearings on the I-290 DEIS were held at two different locations on January 25 and 26, 2017 following the Notice of Availability of the DEIS on December 30, 2016. Approximately 332 unique comments on the DEIS were received and were addressed in the FEIS.

A suite of outreach tools was used to reach all stakeholders, with an emphasis on environmental justice (EJ) communities. These tools included a project website (www.eisenhowerexpressway.com), newsletters, e-mail blasts to a 3,000-count stakeholder mailing list, billboards, content prepared for village websites, and media releases. As a result of this collective outreach and community involvement, more than 1,700 public comments were received and considered from October 2009 to April 2017. The culmination of this robust stakeholder outreach program has resulted in a project that broadly reflects community and stakeholder values in the Project Corridor.

S.4 Alternatives Considered

The process for developing and evaluating alternatives for the I-290 Eisenhower Expressway multimodal corridor consisted of four sequential steps, as shown in Figure S-8.

Figure S-8. Alternatives Development and Evaluation Process

Source: WSP Parsons Brinckerhoff, 2016.

[2] Stakeholder Involvement Plan, Version 6 (2017) http://www.eisenhowerexpressway.com/pdfs/i290_stakeholderinvolvementplan_v5.pdf

Through these four consecutive evaluation steps, a wide range of alternatives was systematically identified, evaluated, and screened down to the identification of four build alternatives and the No Build Alternative to be carried forward for detailed evaluation in the Draft Environmental Impact Statement (DEIS). A range of factors was considered in the evaluation process, including how well the alternatives addressed the Purpose and Need (i.e., regional and local travel performance, access to employment, safety, modal connections and opportunities, and facility deficiencies), environmental constraints, displacements, and stakeholder input.

The process included a close examination of all transit modes within the Study Area, the results of which can provide input into the planning of other area transportation agencies. In partnership with IDOT and the I-290 Study, CTA conducted a concurrent Blue Line Forest Park Branch Feasibility/Vision Study[3] to assess current conditions and identify modernization needs for rail infrastructure and customer amenities for the near and long term in this Project Corridor.

The regional travel demand model from the MPO was adapted for this corridor and used as an evaluation tool for travel performance testing of the alternatives in Rounds 1, 2, and 3. For Rounds 1 and 2, a 2040 baseline or No Build population and employment forecast was used as input in the travel demand model. A total of 33 alternatives (21 in Round 1 and 12 in Round 2) were evaluated with this forecast methodology. For Round 3, a 2040 Build population and employment forecast was developed assuming I-290 corridor capacity and transit improvements, including an additional lane on I-290 in each direction between Mannheim Road and Austin Boulevard, a CTA Blue Line extension to Mannheim Road, and supporting transit feeder services.

No Build Alternative: The No Build Alternative assumes no major capital improvements to I-290 or the CTA Blue Line Forest Park Branch in the Study Area, but includes other major capital projects outside the Study Area included in the Chicago Metropolitan Agency for Planning (CMAP) 2040 fiscally constrained plan. The No Build Alternative is "alternative neutral" and is the baseline condition against which the transportation performance of alternatives is evaluated.

Initial Range of Stakeholder Suggestions: Alternatives suggestions for the I-290 Study were actively solicited from project stakeholders and the public through public meetings, CAG/Task Force (TF) meetings, stakeholder meetings, and public comments. A total of 570 suggestions were submitted regarding alternatives.

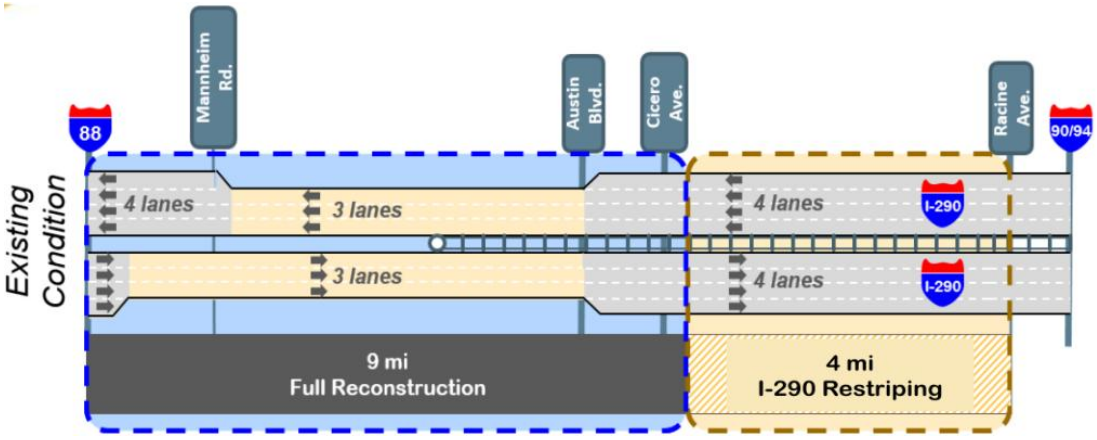
Round 1 – Single Mode Alternatives Identification and Evaluation: After condensing the 570 alternatives into 33 concept categories, they were prescreened to identify "single mode" alternative concepts to be carried forward for evaluation in Round 1. From these 33 concept categories, 21 single mode transit, highway, and arterial alternatives were developed by the project team and CAG/TF for evaluation in Round 1: eleven I-290

[3] Blue Line Forest Park Branch Feasibility/Vision Study Website: http://www.transitchicago.com/blueweststudy/

expressway alternatives, nine transit alternatives, and one arterial highway widening alternative. The arterial highway widening alternative was fatally flawed due to limited available right-of-way and potential impacts. The remaining 20 alternatives were evaluated with respect to transportation performance criteria, and the results were used to inform the next round of alternatives development. It was determined that the expressway alterantives provide the best overall performance and stand alone transit alternatives did not improve I-290 performance, but have other benefits. The results of Round 1 were used to inform the next round of alternatives development.

Round 2 – Combination Mode Alternatives Identification and Evaluation: Based on the findings of the Round 1 single mode alternative evaluation, combination mode alternatives were assembled for evaluation in Round 2. The approach was to test the overall performance of the expressway modes in combination with additional benefits of transit modes. The Round 2 alternatives tested included two transit modes, Express Bus service (EXP) or a combination EXP and High Capacity Transit (HCT) extension to Mannheim Road, in combination with the following expressway modes: General Purpose (GP) Lanes (all lanes non-tolled GP lanes); High Occupancy Vehicle (HOV) 2+ (one HOV lane and three GP lanes in each direction); Toll (all lanes tolled); High Occupancy Toll (HOT) 3+ (one HOT lane and three GP lanes in each direction); and an expressway alternative that paired Toll Lanes and HOT 3+.

Each of these ten combination alternatives featured a highway lane addition in each direction within the existing six-lane section of I-290. During the evaluation of the initial 10 combination mode alternatives, the CAG identified two additional combination mode alternatives that combined transit and expressway management strategies, but without a lane addition in the existing six-lane section of I-290.



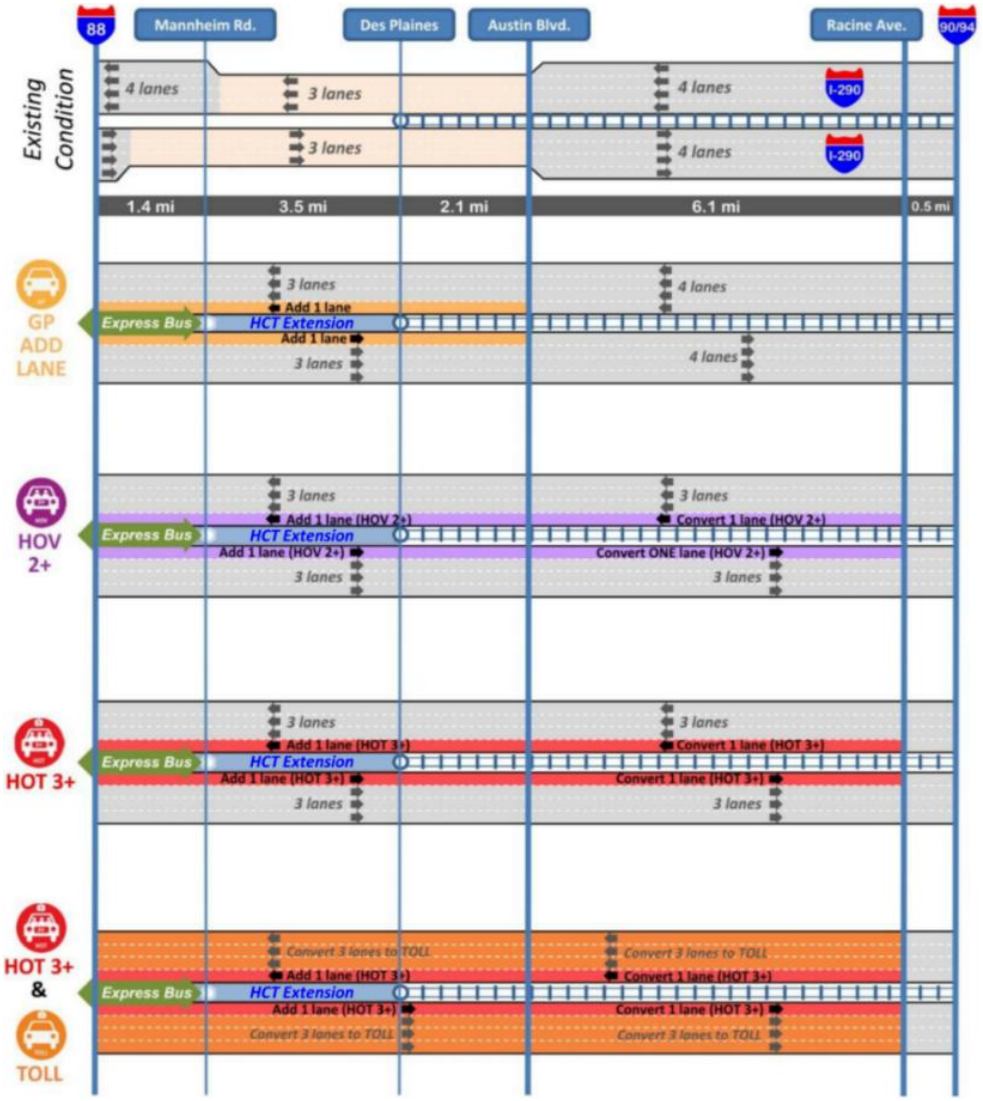
The alternatives were scored against the project purpose and need two ways, using "rank" scoring (where each need point category contributes equally to the overall score) and "ratio" scoring (weighting for each measure based on the relative performance differences between the alternatives). Based on the results of the Round 2 evaluation, the top four performing alternatives were advanced for further evaluation in Round 3.

Round 3 – Further Definition and Refinement of Build Alternatives: In Round 3, the Study Area was formally extended an additional 4 miles east to Racine Avenue (Section 2.5.1) to connect to the improvements being constructed at the Jane Byrne interchange. Interchange type and expressway access studies were layered in with the further design refinement and detailed performance and environmental evaluation of alternatives in Round 3.

Full reconstruction of the expressway from west of Mannheim Road to east of Cicero Avenue is required to accommodate mainline capacity and interchange improvements. Based on condition assessment and operational analysis of the build alternatives, no new expressway reconstruction or capacity improvements were identified for the eight-lane section; at most, only a restriping and appropriate signage of the eight-lane section is required to implement a build alternative. As such, reconstruction of the eight-lane section east of Cicero Avenue is not proposed; however, the condition of the overhead

bridges in this section is being addressed as part of a separate study. Figure S-9 shows the Project Corridor sections.

Figure S-9. I-290 Project Corridor Sections



Source: WSP Parsons Brinckerhoff, 2016.

The top four alternatives identified in Round 2 for further development and refinement in Round 3 are described as follows. Figure S-10 shows a graphic description of the four build alternatives.

- **GP & EXP & HCT** (also referred to herein as GP Lane), consisting of adding one GP lane[4] in each direction between 25th Avenue and Austin Boulevard and includes provisions for EXP and HCT;
- **HOV 2+ & EXP & HCT** (also referred to herein as HOV 2+), consisting of adding one HOV 2+ (two or more occupants required for use) lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing GP lane in each direction west of 25th Avenue and east of Austin Boulevard to HOV use, and provisions for EXP and HCT;
- **HOT 3+ & EXP & HCT** (also referred to herein as HOT 3+), consisting of adding one HOT 3+ (three or more occupants per vehicle required for non-tolled use, or one/two occupants per vehicle paying a toll) lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing GP lane in each direction west of 25th Avenue and east of Austin Boulevard to HOT 3+ use, and provisions for EXP and HCT; and

[4] "General purpose lanes (also referred to as "mixed-use" or "mixed-flow" lanes) are those where use is allowed by all vehicles (except certain small motorized vehicles, bicycles, and pedestrians on limited-access highways), without restriction on number of occupants or imposition of a toll. All lanes on I-290 are currently GP.

Figure S-10. Four Build Alternatives Advanced to DEIS

Source: WSP Parsons Brinckerhoff, 2016.

- **HOT 3+ & TOLL & EXP & HCT** (also referred to herein as HOT 3+ & TOLL), consisting of adding one HOT 3+ lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing GP lane in each direction west of 25th Avenue and east of Austin Boulevard to HOT 3+ use, conversion of the remaining GP lanes to toll lanes (all users of these lanes paying a toll), and provisions for EXP and HCT.

The proposed footprint and interchange concepts are the same for each build alternative. Notable interchange concepts include: 1) reconstruction of 25th and 1st Avenue interchanges as Single-Point Urban Interchanges (SPUI), 2) reconstruction of Harlem Avenue and Austin Boulevard interchanges, which currently have left-hand ramps, to a modified SPUI design with right-hand ramps that retain a center intersection where the ramps converge with the cross road, 3) a braided ramp design between Austin

Boulevard and Central Avenue interchanges, and 4) reconfiguring ramps between Cicero Avenue and Laramie Avenue to remove a substandard mainline weaving condition and adding in frontage road U-turns to improve local circulation.

The travel performance of the four Round 3 build alternatives was evaluated using 2040 Build population and employment forecasts and compared to the No Build Alternative. A detailed comparison of the travel performance of the alternatives is shown in Table S-1. For clarity, table values in red in the Transportation Performance (2040), Social / Economic, Air Quality, Traffic Noise, and Natural Resources-Floodplains sections represent reduced performance or greater impacts as compared to the No Build Alternative, and table values in green in these sections represent better performance or lesser impacts as compared to the No Build Alternative.

Other Round 3 Refinements and Considerations: Based on the findings for the right-of-way and profile evaluations and in consideration of CTA's Blue Line Forest Park Branch Feasibility/Vision Study findings, the proposed expressway design is configured to accommodate a future HCT guideway along the median of I-290 from 1st Avenue to east of Mannheim Road, uses 10 feet of CTA right-of-way from west of Circle Avenue to east of Austin Boulevard to provide improved expressway safety performance, and improves clearances over the CSX Railroad to a minimum of 21-feet 9-inches via reduced cross-road bridge depths and minor track lowering. Intelligent Transportation System (ITS) components are recommended to facilitate lane management and to further improve safety. A diagram of the four build alternatives carried forward for detailed evaluation in the DEIS (and the FEIS) is shown in Figure S-10.

CTA Blue Line Forest Park Branch Feasibility/Vision Study findings: The CTA's findings include the need for reconstruction of the entire Forest Park Branch. Other key recommendations include:

- Maintain existing entrance locations;
- Remove stations closed in 1970s;
- Improve infrastructure to a state of good repair;
- No third track or express service;
- Improve the terminal site at Forest Park;
- Maintain existing service; and
- Work with IDOT on Project Corridor improvements through design, construction, and funding.

In the short term, CTA would continue to perform interim work to address slow zones and other maintenance items.

Table S-1. Comparison Matrix of Alternatives

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
1.0	**Transportation Performance (2040)**						
1.1	Regional vehicle miles traveled (VMT) (miles)	Quantitative	201,187,710	+151,380	+72,492	+52,211	+33,774
1.2	Regional vehicle hours traveled (VHT) (hours)	Quantitative	8,067,709	-9,840	-9,773	-16,161	-17,300
1.3	I-290 Travel Time (Min) (GP/ML)	Quantitative	30.7 / NA	21.2 / NA	23.2 / 13.7	23.0 / 13.5	14.8 / 12.6
1.4	Study Area Arterial VMT (miles)	Quantitative	4,294,011	-24,560	+6,944	-8,853	+147,834
1.5	Study Area Arterial VHT (Hours)	Quantitative	255,282	-1,996	-967	-1,643	+6,778
1.6	Person Throughput	Quantitative	459,122	+25,247	+31,871	+28,604	+25,294
1.7	Job Accessibility	Quantitative	5,151,539	+105,053	+364,948	+397,660	+326,499
1.8	Overall Safety (crashes per million person miles per year)	Quantitative	0.287	-4.86%	-6.44%	-6.21%	-4.65%
1.9	East-West Transit Trips	Quantitative	76,950	+4,375	+2,150	+4,425	+8,425
2.0	**Social/Economic (including Environmental Justice)**						
2.01	Traffic diversion to local roads (VMT)	Quantitative	--	-24,560	+6,944	-8,853	+147,834
2.02	Average change in travel time to job destinations from the 2040 No Build Alternative, Environmental Justice (EJ) Communities	Quantitative	--	-1 to -3 minutes	0 to -9 minutes	-1 to -10 minutes	-1 to -9 minutes
2.03	Average change in travel time to job destinations from the 2040 No Build Alternative, non-EJ Communities	Quantitative	--	-2 minutes	-2 to -5 minutes	-2 to -5 minutes	-4 to -6 minutes
2.04	Bicycle and Pedestrian accommodations	Qualitative	No change in existing condition	Provision of a new east-west separated shared path from DesPlaines Avenue to Austin Boulevard (approximately 2 miles); improved pedestrian crossings; new pedestrian refuge islands; improved pedestrian/bicycle safety with new/wider sidewalks; improved shared-use path connectivity; improved pedestrian/bicycle accommodations at I-290 cross roads.			
2.05	Housing units displaced	Quantitative	0	0			

Table S-1. Comparison Matrix of Alternatives (continued)

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
2.06	Public services displaced	Quantitative	0	0			
2.07	Businesses displaced	Quantitative	0	0			
2.08	Construction-related jobs created	Quantitative	--	18,904	18,904	18,980	18,980
2.09	Productivity (based on travel time savings)	Quantitative	--	+$1.6 B	+$1.6 B	+$2.7 B	+$2.9 B
2.10	Consistency with local and regional plans	Qualitative	No Effect	CMAP includes capacity improvements in the Project Corridor in its Go To 2040 Plan and classifies improvements to the I-290 Eisenhower Expressway as one of the region's 'priority projects'. The local comprehensive plans for Oak Park, Maywood, Broadview, Hillside, and Bellwood all express a desire to improve access to I-290.			
2.11	Community cohesion	Qualitative	No Effect	Improvements to roadways crossing the highway would improve community cohesion.			
2.12	Land use changes	Quantitative	No Effect	No major land use changes are expected as a result of the project, which mostly stays within existing right-of-way.			
2.13	Right-of-way acquisition	Quantitative	0	5.972 acres of right-of-way (ownership) and permanent easement			
3.0	Historic Resources						
3.1	Historic properties impacted	Qualitative	No Adverse Effect to Historic Properties	No effect to 6 historic properties and no adverse effect to 17 historic properties in the APE. No direct physical impacts to 22 of the 23 historic properties would occur; a temporary easement and proposed improvements would be located in the NHL boundary of Columbus Park, but they would have no adverse effect to the property. No indirect effects to historic properties would occur. FHWA made a no adverse effect finding to built historic properties and the SHPO concurred on May 25, 2017.			

Table S-1. Comparison Matrix of Alternatives (continued)

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
3.2	Parks, Recreational Areas, Wildlife/Waterfowl Refuges						
3.3	Parkland impacts	Quantitative & Qualitative	No Effect	Improved access to the 51 parks and recreation areas along the Project Corridor by new or improved pedestrian and bicycle routes. Pedestrian access improvements requested by the Village of Forest Park require the permanent use of 0.031 acre and the temporary use of 0.137 acre from Veterans Park, the Dog Park, and Park District of Forest Park Recreational Center (Roos Property) within the Village of Forest Park. Section 4(f) exception of 2.74 acres at Columbus Park.			
3.4	Section 4(f)	Quantitative & Qualitative	*de minimis*	*De minimis* impact including 0.031 acre of permanent use and 0.137 acre of temporary use to parks within the Village of Forest Park to accommodate widened and new sidewalks. No other direct or constructive use of publicly owned parks and recreational areas is required by the four build alternatives. The enhancement of 2.74 acres at Columbus Park is an exception to Section 4(f) under 23 CFR 774.13(g).			
4.0	**Visual Resources**						
4.1	Visual impacts/benefits	Qualitative	No Effect	Proposed transportation improvements with respect to the visual environment are the same for all build alternatives. Aesthetic treatments would be evaluated for the Preferred Alternative. 46 of 63 eligible noise barriers were favored by "benefited receptor" stakeholders and are likely to be built, pending future project coordination.			

Table S-1. Comparison Matrix of Alternatives (continued)

7.0	**Hazardous Waste**						
7.1	Hazardous materials REC sites affected	Quantitative	0	495 sites within Project Corridor; 13 sites within or directly adjacent to proposed right-of-way acquisition.			

Table S-1. Comparison Matrix of Alternatives (continued)

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
8.0	**Natural Environment**						
8.1	Wildlife (number of species impacted)	Quantitative & Qualitative	0	0			
8.2	Wetlands (acres)	Quantitative	0	0			
8.3	Floodplains, volume change from existing (acre-feet)	Quantitative	0	-12.94 acre-feet, normal to 100-year flood elevation (overall flood storage capacity increased)			
8.4	Water quality – Are water quality standards met (chlorides, metals, and TSS)? (yes/no)**						
	Salt Creek	Quantitative & Qualitative	Yes	Yes			
	Des Plaines River	Quantitative & Qualitative	Yes	Yes			
	South Branch of Chicago River	Quantitative & Qualitative	Yes	Yes			
9.0	**Other**						
9.1	Construction cost	Quantitative	--	$2,558M	$2,558M	$2,571M	$2,571M
9.2	Toll revenue (2040 annual revenue in 2014 $)	Quantitative	--	--	--	$20M	$100M

* Per policy, noise impacts are only identified for the build condition.

** Increased concentration and loading for any build alternative would be offset with BMP and deicing practices.

S.5 Environmental Resources, Impacts, and Mitigation

The Study Area is situated in a highly developed urban environment and, as such, there are limited existing natural environmental resources. The primary environmental consideration is the communities along the corridor and the environmental impacts that affect them. All requisite environmental resources were evaluated and are documented in the FEIS. A detailed comparison of the impacts for each alternative is shown in Table S-1. For clarity, table values in red in the Transportation Performance (2040), Social/Economic, Air Quality, Traffic Noise, and Natural Resources-Floodplains sections represent reduced performance or greater impacts as compared to the No Build Alternative, and table values in green in these sections represent better performance or lesser impacts as compared to the No Build Alternative.

The primary environmental factors evaluated in the context of this corridor are summarized below.

Social/Economic Impacts: The Project Corridor traverses highly developed areas of the Chicago metropolitan region and is almost fully built-out with little unused underdeveloped urban land. The predominant racial groups in the Project Corridor are Whites at 29.8 percent of the total population, Black at 58.1 percent, and 9.7 percent of the population considers themselves Hispanic or Latino. Median household incomes for all core communities are higher than the poverty guidelines. Westchester and Elmhurst had the lowest percentages of persons living below the poverty line, while communities with the highest percentages below poverty were generally found on the eastern portion of the corridor. Chicago has the highest percentage of persons below the poverty line at 21.4 percent.

Year 2040 No Build and Build socio-economic forecasts were prepared as part of the I-290 Study based on the change in highway and transit accessibility. The I-290 Study Area population and employment forecasts for the No Build versus Build Scenario indicate a less than one percent change due to the existing built-out urban conditions in the Study Area and that the proposed project reflects improvements to an existing facility that already provides accessibility to the Study Area. All of the build alternatives would result in long-term benefits from improved access to and from I-290 and annual productivity savings in 2040 that would range from $86 to $152 Million.[5] The build alternatives would not change land use patterns and comply with local and regional comprehensive plans. All existing access points to I-290 would be maintained. There would be no residential or business displacements, and 5.972 acres of right-of-way (ownership) and permanent easement would be required.

[5] Productivity savings is travel time savings multiplied by the time value of money. Assumes $24 per hour value of time per the NCHRP Report 456 Guidebook for Assessing the Social and Economic Effects of Transportation Projects.

Environmental Justice: No substantial differences in transportation access were found with any of the build alternatives with respect to EJ communities, as compared to non-EJ communities, and all build alternatives had benefits in job accessibility and nonmotorized and transit access for EJ communities that were similar to non-EJ communities. Of the build alternatives, the HOT 3+ & TOLL Alternative impacted the 2040 arterial traffic more than the No Build Alternative, while the other three build alternatives showed positive effects. Environmental effects, such as those to air, noise, and social and economic resources (including construction impacts), were similar for EJ and non-EJ communities, and no residences or businesses in either EJ or non-EJ communities are proposed to be displaced by any of the build alternatives. Public involvement was encouraged by the participation of representatives of EJ communities in the project's CAG study group, as well as traditional and nontraditional means of engaging the public in participation at public and community meetings. Though there would be impacts (i.e., noise and construction impacts in particular) to EJ and non-EJ communities along the Study Area, upon implementation of the planned mitigation, as described in this EIS, and coordinated with each community, the impacts would not be disproportionately high and adverse to EJ communities.

Cultural Resources Impacts: Within the Area of Potential Effects (APE), existing resources include one National Historic Landmark (NHL) property, Columbus Park, five National Register of Historic Properties (NRHP)-listed properties, and one historic district pending NRHP designation. Two historic properties, including one district, were previously determined eligible for inclusion in the NRHP for a total of the nine NRHP-listed and previously determined NRHP-eligible properties within the APE. Based on an intensive-level survey of the cultural resources 50 years of age or older, 14 additional historic properties within the APE were determined eligible for inclusion in the NRHP.

A comprehensive assessment of the project's potential effects to historic properties was completed and submitted in a report to the State Historic Preservation Officer (SHPO) and the Section 106 consulting parties for review and comment. Based on FHWA's Section 106 effect finding, the Preferred Alternative would have no effect to six historic properties and no adverse effect to 17 historic properties in the APE. A consulting parties meeting was also held to discuss the effects findings and provide an opportunity for the consulting parties to comment. These effects findings and additional consultation have been summarized and included in this combined Final Environmental Impact Statement (FEIS)/Record of Decision (ROD).

No direct physical impacts to 22 of the 23 historic properties would occur as a result of the Preferred Alternative because the proposed improvements generally fit within existing right-of-way, outside of NRHP boundaries. Project activity is proposed within the NHL boundary of Columbus Park, but the proposed enhancements would have no adverse effect to the property, and qualify for a Section 4(f) exception under 23 CFR 774.13 (g). Additionally, no indirect effects to historic properties would occur because traffic noise and visual project components would not adversely diminish their integrity or alter the characteristics qualifying these properties for the NRHP. Therefore, FHWA made an overall project finding of no adverse effect.

Traffic Noise Impacts: Under existing conditions, 220 of the 288 noise receptors identified currently approach or exceed the Noise Abatement Criteria (NAC).[6] Of the four build alternatives, the HOT 3+ & TOLL Alternative resulted in the fewest receptors that approach, meet, or exceed the NAC (220 receptors), while the GP Lane Alternative has the greatest number (230 receptors). The No Build Alternative, HOV 2+, and HOT 3+ alternatives also had similar effects (227, 228, and 229 receptors respectively). The slight difference in traffic noise impacts among the build alternatives correlates to their traffic volume differences, with the HOT 3+ & TOLL Alternative having the lowest projected traffic volumes and affected receptors and the GP Lanes Alternative having the highest projected traffic volumes and affected receptors.

Air Quality: Air quality analysis of the four build alternatives included pollutant burden analysis, Mobile Source Air Toxics (MSATs), and greenhouse gas (GHG) emissions. Overall, the build alternatives are expected to show minor changes (generally less than one percent better or worse) in regional pollutants, GHG emissions, and MSATs compared to the No Build Alternative, and no local impacts are currently identified. Of the four build alternatives, the HOT 3+ Alternative provided the best overall air quality benefits, with reductions in all of the air quality measures evaluated.

Natural Resources Impacts: The build alternatives are located predominantly in developed areas associated with existing roadways. No impacts to forest preserves or state-designated lands are proposed, and all of the four build alternatives would result in the same impacts to habitat. Overall, project-related impacts to wildlife associated with the build alternatives would be minimal.

Water Resources/Quality: Each of the four build alternatives would cross three streams: Addison Creek, the Des Plaines River, and the South Branch of the Chicago River. For Addison Creek and the South Branch, no change in pollutant concentrations would occur. Addison Creek receives no runoff from I-290, and the I-290 drainage to the South Branch is unchanged from existing to the No Build and build condition. There would be an increase in chloride loading to the Des Plaines River associated with the build alternatives. Given the chloride impairment of the Des Plaines River, IDOT would use best management practices (BMPs) to offset the potential increase to the Des Plaines River, as discussed in Section 3.7.3.

Floodplains Impacts: There would be a small amount of proposed net fill in the Des Plaines River floodplain, while there would be a net cut in the Addison Creek floodplain; the net benefit would be 12.94 acre-feet of additional storage from the normal to the 100-year flood elevation for both floodplains within the Study Area. No floodway impacts are anticipated at Addison Creek or the Des Plaines River with the build alternatives.

[6] Per IDOT policy, traffic noise impacts are identified only for the future build condition, not for the existing or future No Build condition. Comparisons of the existing and future No Build noise levels to the NAC are for comparison purposes only.

Special Waste/Hazardous Waste Impacts: The Illinois State Geological Survey (ISGS) Preliminary Environmental Site Assessment (PESA) reports identified numerous recognized environmental condition (REC) sites, all of which have the potential for soil or groundwater contamination and could potentially pose a risk to construction activities. Thirteen (13) REC sites were identified as being within or directly adjacent to the proposed right-of-way acquisitions. These REC sites may require further evaluation including testing (preliminary site investigation [PSI]). The determination whether further assessment is necessary will be evaluated as the proposed project progresses and detailed design becomes available. The decision generally depends on the nature of the REC, its proximity to the planned construction activities, and its potential impact to the proposed project. Mitigation is discussed in Section 3.11.3.

Special Lands: The proposed project would require small areas of new right-of-way from two parks in the Village of Forest Park to accommodate pedestrian and bicycle access improvements requested by the Village and the temporary use of a third park during construction. The proposed improvements would occur as follows:

- Veterans Park (at 631 Circle Avenue): 0.027 acre (temporary)/0.018 acre (permanent) to provide for a wider, 12-foot wide sidewalk and a new on-street 6-foot wide bicycle lane along Circle Avenue, and a new sidewalk on the park's western boundary to connect the park with the proposed shared-use path (requested by the Village).
- The Dog Park (at 632 Circle Avenue): 0.019 acre (temporary)/0.013 acre (permanent) to provide for a wider, 10-foot wide sidewalk along Circle Avenue and a new on-street 6-foot wide bicycle lane (requested by the Village).
- Park District of Forest Park (Recreational Center-Roos property): 0.091 acre (temporary) to provide work space for installing a 5-foot wide sidewalk on the west side of Circle Avenue south of I-290.

As stated in Section 3.12.3, FHWA issued a *de minimis* impact finding in this FEIS for Veterans Park, the Dog Park, and the Roos Property based on the minimization measures proposed and concurrence received from the Officials with Jurisdiction (OWJs) that there is not an adverse effect to the features, attributes, and activities that make the properties eligible for 4(f) protection. The project would not adversely impact the long-term use, function, or development of these parks.

At Columbus Park, the project proposes to enhance bicycle and pedestrian access along the southern boundary of Columbus Park between Austin Boulevard and Central Avenue north of I-290 where no connectivity currently exists. This access improvement would require work space of approximately 1.03 acres in the southwestern corner of the park to allow construction of a 450-foot long shared-use path. This would provide a connection from the proposed shared-use path at Austin Boulevard, connecting to the park's existing trail, thus providing continuous nonmotorized access between the Illinois Prairie Path at DesPlaines Avenue to Central Avenue. Landscape enhancements would also be undertaken along the eastern half of the park's southern boundary requiring work space of 1.71 acres. The Chicago Park District and SHPO concurred that these

improvements have no adverse effect on the park and that the requirements of 23 CFR 774.13(g) for a Section 4(f) exception have been met.

Visual Resources: In those sections to be reconstructed along the Project Corridor, an effort will be made to create a consistent corridor aesthetic. While the final design is yet to be completed, the general appearance of walls, noise barriers, bridge piers, and fencing is anticipated to include the textures and forms illustrated in Section 3.13.4.

The quality and character of the existing viewsheds of the Project Corridor as viewed from the adjacent land uses is a result of the original I-290 construction. Since that time, the density and quality of existing vegetation affects the ability to view one side of the corridor from the other where the right-of-way is wider and the vegetation is densest. The primary visual consequence of the build scenarios as viewed from outside the corridor would be the loss of this vegetation and the potential placement of noise barriers. To mitigate for this loss, the retaining walls and other structures would be located such that the maximum amount of green space is created between the new retaining walls and the adjacent off-corridor land uses. Where space permits, landscape planting would be installed to restore the lost vegetation and to soften the appearance of the noise barriers, as described in Section 3.13.5.2.

Indirect and Cumulative Impacts: Indirect impacts are those caused by an action and are later in time or further removed in distance but are still reasonably foreseeable. Cumulative impacts result from the incremental consequences of an action when added to other past and reasonably foreseeable future actions. Analysis of indirect and cumulative impacts of the build alternatives includes effects on regional growth and development patterns, as well as air and water quality, noise, wetlands, biological and cultural resources, and other resources. The geographic extent of these analyses varies with the resource. A summary of findings is as follows:

- Indirect population and employment effects of the build alternative, as well as cumulative effects, are limited by the Study Area's urban, largely developed character.
- Air quality was evaluated in a regional context and no indirect or cumulative impacts are anticipated.
- Traffic noise impacts are anticipated to be direct; the project is not expected to have a cumulative effect on regional noise levels, but noise would be reduced in the Study Area by installation of noise barriers.
- Where there are no direct impacts to natural resources (e.g., wetlands) or adverse impacts to cultural resources, the indirect and cumulative impacts of the build alternatives are not anticipated to be different than status quo development within the Study Area.
- Increased traffic and impervious surfaces have a potential effect on water resources; maintaining water quality standards and utilizing BMPs are anticipated to minimize adverse indirect and cumulative impacts to water resources in the Study Area.

Please refer to Section 3.15 for a complete evaluation of these impacts.

Potential Mitigation: Mitigation and abatement measures would be completed in accordance with the policies and procedures of FHWA and IDOT and the requirements of the appropriate federal and state resource agencies. Section 3.19 provides a detailed summary of mitigation commitments. Due to the limited amount of right-of-way required and that there are no displacements for any of the build alternatives, few mitigation measures are required. Some of the primary mitigation measures identified are:

- Forty-six (46) noise walls, which would benefit 4,027 receptors, were determined reasonable and feasible after completing the viewpoints solicitation. Future coordination in the design phase may result in reopening the viewpoints solicitation process where warranted by changes in the number/location of benefited stakeholders, the benefited stakeholders' opinions, or noise wall technology. The noise barriers likely to be constructed are shown in the Section 3.0 Map Set.
- Mitigation for visual impacts may include implementation of context sensitive design, which involves public input, and landscape improvements for the replacement of existing landscaping, creation of new landscape areas, public input in the use of alternative materials and design of noise barriers, and installation of containerized plantings located on the cross-road overpass bridges.
- Impacts to trees would be minimized with installation of construction fencing and exclusion zones to reduce compaction of roots and soil. Mitigation for trees removed would be guided by IDOT's Preservation and Replacement of Trees (IDOT, 2002) policy and Chapter 59 ("Landscape Design") of the Bureau of Design and Environment (BDE) Manual (IDOT, 2014).
- A landscaping plan would be developed during the design phase that would identify areas where trees, shrubs, and grasses would be planted on highway side slopes, on back slopes, and in the median, except where clear vision needs to be maintained at highway entrances and exits, intersections, and median openings.

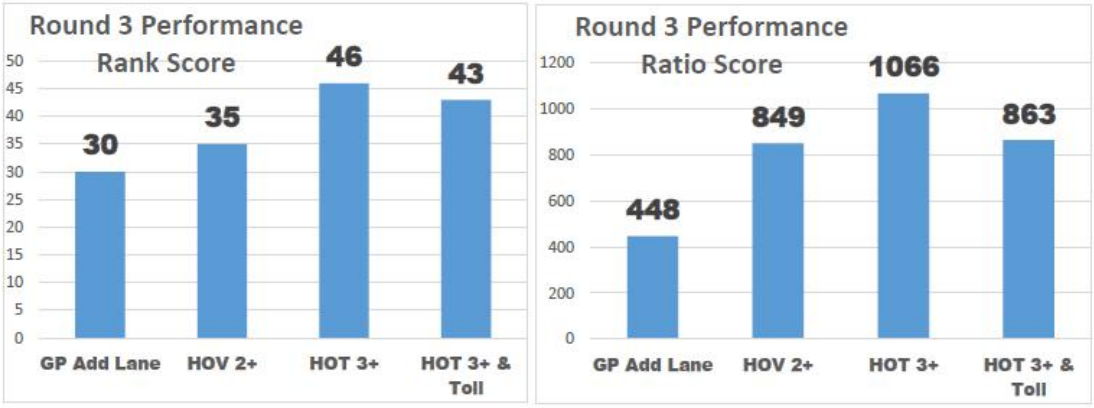
S.6 Comparison of Alternatives

Because the build alternatives have identical footprints, they are generally very similar to one another. The primary differences between the alternatives are related to travel performance and social, economic, and environmental impacts due to the manner in which traffic would be managed and the differences in traffic volumes and patterns resulting from this management.

The proposed improvements are almost entirely contained within existing I-290 right-of-way, with the exception of 5.972 acres including proposed right-of-way (ownership) and permanent easement near five interchanges and a 10-foot wide strip of right-of-way from the CTA Blue Line. As desired by the communities, no residential or commercial displacements would result from the build alternatives, and all I-290 interchange access locations would be retained. Each of the four build alternatives accommodates

improvements to the existing HCT (the CTA Blue Line) where it exists today and provides for a westward expansion of HCT to Mannheim Road.

With regard to environmental resources, the four build alternatives have no impacts to wetlands, wildlife, and agricultural resources and result in the same 12.94 acre-feet net decrease in floodplain fill volume. There would be no direct use of adjacent Section 4(f) resources required by any of the build alternatives except for a *de minimis* impact to public parkland in the Village of Forest Park, as well as a Section 4(f) exception at Columbus Park to provide new trail connections and other amenities. Effects to historic properties are undifferentiated among the alternatives, as each would have no effect to six historic properties and no adverse effect to 17 historic properties in the APE. No indirect effects to historic properties would occur because traffic noise and visual project components would not adversely diminish their integrity or alter the characteristics qualifying these properties for the NRHP.



When comparing the evaluation measures of all four alternatives against the No Build Alternative, the HOT 3+ Alternative scored highest in rank and ratio scoring, with 46 out of 64 possible points by rank (ordinal) scoring and 1,066 out of 1,600 possible points by ratio scoring, as shown in Table S-2 and Figure S-11.

Table S-2. Build Alternatives Rank and Ratio Scoring Comparison Matrix

#	Round 3 DEIS Performance Measure	Unit	No-Build	GP Add Lane	HOV 2+	HOT 3+	HOT 3+ & Toll
1.1	Regional vehicle miles traveled (VMT)	miles	201,187,710	151,380	72,492	52,211	33,774
1.2	Regional vehicle hours traveled (VHT)	hours	8,067,709	-9,840	-9,773	-16,161	-17,300
1.3	I-290 Travel Time (GP Lane / Managed Lane)		30.7/NA	21.2/NA	23.2/13.7	23/13.5	14.8/12.6
1.4	Study Area Arterial VMT	miles	4,294,011	-24,560	6,944	-8,853	147,834
1.5	Study Area Arterial VHT	hours	255,282	-1,996	-967	-1,643	6,778
1.6	Person Throughput	persons	459,122	25,247	31,871	28,604	25,294
1.7	Job Accessibility	# of jobs	5,151,539	105,053	364,948	397,660	326,499
1.8	Overall Safety (crashes per million person miles per year)	rate	0.287	-4.86%	-6.44%	-6.21%	-4.65%
1.9	East-West Transit Trips	# of trips	76,950	4,375	2,150	4,425	8,425
2.01	Traffic Diversion to Local Roads	VMT	4,294,011	-24,560	6,944	-8,853	147,834
2.02	Average Change in travel time to job destinations, EJ Communities	Min	-	-1 to -3	0 to -9	-1 to -10	-1 to -9
2.03	Average Change in travel time to job destinations, Non-EJ Communities		-	-2 to -2	-2 to -5	-2 to -5	-4 to -6
2.08	Construction related jobs created	#	-	18,904	18,904	18,980	18,980
2.09	Productivity (based on travel time savings)	$B	-	$ 1.6	$ 1.6	$ 2.7	$ 2.9
6.1	Noise Receptors approaching, meeting, or exceeding noise abatement criteria (NAC)		227	230	228	229	220
9.1	Round 3 Construction Cost Difference ($ Millions)		$ -	$ -	$ -	$ 13	$ 13
		Rank Score (1 to 4)		30	35	46	43
		Ratio Score (0 to 100)		448	849	1066	863

In considering the key factors identified with respect to meeting project goals and objectives, travel performance, and social/economic and environmental impacts, the HOT 3+ Alternative provides the best balance of benefits, avoids social/economic and environmental impacts, and provides travel benefits to EJ communities. The HOT 3+ Alternative results in a 25 percent travel time savings in the GP lanes and a 56 percent travel time saving for users of the managed lane (Figure S-12).

Figure S-12. HOT 3+ Alternative Typical Section and Travel Time Improvements

Source: WSP Parsons Brinckerhoff, 2016.

The managed lane can be used for free by cars with three or more occupants and by transit, as shown in Figure S-12. The managed lane offers more travel choices for all users of the facility and offers a reliable trip time. With the potential contribution from anticipated toll receipts from the HOT lanes, the HOT 3+ Alternative also provides additional flexibility in funding to the initial construction cost, as well as ongoing operation and maintenance.

Based on these factors, the HOT 3+ Alternative is selected as the Preferred Alternative.

S.7 Other Proposed Actions

The major federal and state transportation projects identified as other actions are described in full in CMAP's GO TO 2040 Comprehensive Regional Plan. The largest nearby project is the I-290 Jane Byrne (formerly Circle) Interchange Reconstruction Project, which began construction in 2013, near the eastern limits of the Study Area. That project would improve circulation between I-290 and I-90/I-94.

S.8 Major Unresolved Issues with Other Agencies

There are no unresolved issues at this time.

S.9 Other Federal Actions Required for the Proposed Action

As described in Section 3.18, federal permits will be required prior to construction. There are no other federal actions needed for this FEIS in connection with the I-290 Reconstruction Project. An Access Justification Report is being prepared for FHWA approval to document operational changes of the I-290 Preferred Alternative associated with proposed interchange improvements.

Eisenhower expressway

I-290 | Eisenhower Expressway

From west of Mannheim Road to Racine Avenue

Purpose & Need

June 2017

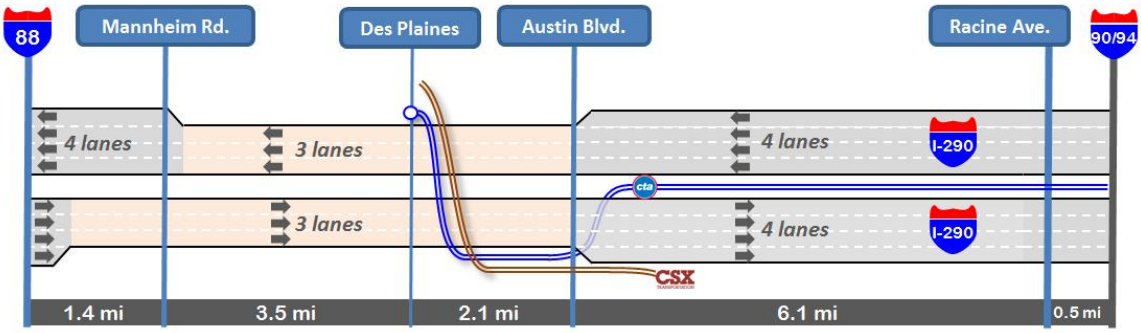
Illinois Department of Transportation

U. S. Department of Transportation
Federal Highway Administration

1.0 Purpose and Need for Action

There have been no substantive changes to this section since publication of the DEIS.

The Interstate 290 (I-290) Eisenhower Expressway provides the primary east-west roadway access to the Chicago central business district. It serves northwest Cook County and DuPage County, connecting to the Reagan Memorial Tollway (I-88) and the Tri-State Tollway (I-294) on the west, and I-90/I-94 (Kennedy and Dan Ryan Expressways) on the east. A parallel Chicago Transit Authority (CTA) rail transit facility, the Blue Line Forest Park Branch is co-located in the eastern portion of the corridor along I-290, serving transit passenger travel between Forest Park and Chicago. CSX Transportation also has freight railroad right-of-way co-located in the western portion of the Study Area.



1.1 Project Background

The Eisenhower Expressway (I-290), originally constructed as the Congress Expressway, was one of the first multimodal facilities in the United States. Opened to traffic in sections beginning in the mid to late 1950's, this facility was designed and constructed according to early standards that were newly created for the interstate highway system.

During the original construction of the Eisenhower Expressway, the CTA Garfield Park rapid transit branch was removed and replaced with what is now known as the Blue Line Forest Park Branch. This heavy rail transit line was constructed parallel to the Eisenhower Expressway, running along the south side of the roadway or in the median. As part of the construction of the Eisenhower Expressway, the freight railroad owned by Baltimore & Ohio Chicago Terminal Railroad, which ran at-grade along the current alignment of the Expressway, was grade-separated and relocated adjacent to the south side of the CTA tracks, sharing the same "cut" with the CTA and the expressway from east of DesPlaines Avenue to Central Avenue. This freight rail line is now owned and operated by CSX Transportation. This section of rail is part of CSX's Altenheim Subdivision and includes the right-of-way for three tracks, including two continuous tracks and a third intermittent track. A portion of the former Chicago, Aurora and Elgin electric interurban railway was also relocated at Forest Park as part of the original expressway construction, but passenger service on that line was discontinued in 1957.

West of Mannheim Road and east of Austin Boulevard, I-290 has four lanes in each direction (Figure 1-1). Between Mannheim Road and Austin Boulevard, I-290 has three lanes in each direction. This reduction in lanes and reduced capacity has been a long standing source of safety, operational, and capacity concerns.

Figure 1-1. I-290 Existing Configuration

Source: WSP Parsons Brinckerhoff, 2015.

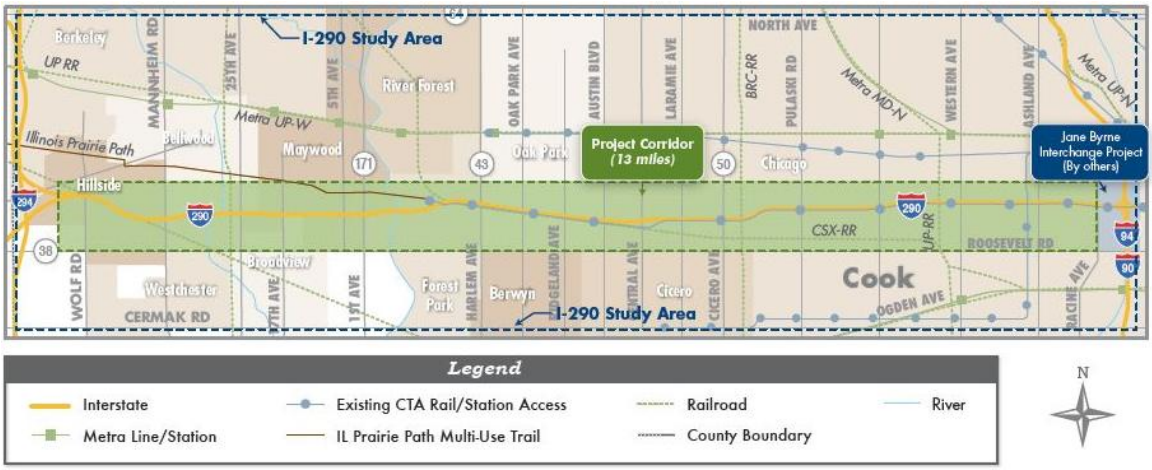
Since its original construction, I-290 has undergone periodic resurfacing and maintenance throughout the corridor. In 2001, the Hillside Interchange Reconstruction Project, located on the west end of the Study Area, was completed. This project was a spot improvement that addressed the Mannheim Road Interchange, and in doing so, addressed safety and operations at I-88's connection with I-290 and improved connections with Mannheim Road. While weaving conflicts on I-290 were reduced by the addition of the eastbound collector-distributor roadway, the project did not address capacity needs along the I-290 mainline. In 2010, 27 miles of I-290 from Thorndale Avenue to I-90/I-94 were resurfaced, and 37 bridges were repaired.

Jane Byrne Interchange
The Jane Byrne Interchange, formerly referred to as the Circle Interchange, is undergoing a 4-year reconstruction from 2014 to 2018.

In 2012, the Illinois Department of Transportation (IDOT) initiated a Phase I preliminary engineering study for the I-90/I-94 and I-290 Jane Byrne Interchange, whose western study limits extend to Racine Avenue on I-290. This improvement project includes widening of the northbound-to-westbound ramp from I-90/94 to I-290 and the eastbound-to-northbound ramp from I-290 to I-90/I-94 from one to two lanes, as well as multimodal transportation system improvements, including wider sidewalks and improved access to public transit.

The I-290 Eisenhower Expressway is identified as a fiscally constrained major capital project in the region's metropolitan transportation plan adopted by the Metropolitan Planning Organization (MPO) Policy Committee, which is the designated MPO for the northeast Illinois region.

1.2 Project Purpose



The purpose of this proposed project is to provide an improved transportation facility along the I-290 Eisenhower Expressway multimodal corridor. More specifically, the purpose of the project is to improve: 1) mobility for regional and local travel; 2) access to employment; 3) safety; 4) modal connections and opportunities; and 5) transportation facility deficiencies.

1.3 Study Area

The Study Area is centered along I-290 in Cook County, extending from west of Mannheim Road to Racine Avenue. The northern boundary of the Study Area is North Avenue, and the southern boundary is Cermak Road, an area of approximately 55 square miles.

The Study Area, shown in Figure 1-2, includes adjacent transit and freight railroads, interchanges, cross streets, and other parallel and crossing features that are within or in close proximity to I-290.

Figure 1-2. I-290 Study Area

Source: WSP Parsons Brinckerhoff, 2015.

The logical termini for the I-290 Study are identified as I-290 west of Mannheim Road (where there are currently four lanes in each direction) to Racine Avenue (adjacent to the Jane Byrne Interchange project). These rational end points were selected to evaluate a continuous section of the expressway corridor between two system interchanges. The scope of the I-90/I-94 at I-290 Jane Byrne Interchange project is to improve operations, safety, and capacity of that interchange. In addition, CTA, in cooperation with IDOT, is conducting a *Blue Line Forest Park Branch Feasibility/Vision Study* and associated facilities, which are currently located within the logical termini. The purpose of this parallel study is to determine CTA's near- and long-term vision for the Blue Line corridor and coordinate those objectives with the I-290 Study. Overhead crossroad bridges in the I-290 Study Area east of Kostner Avenue are being studied by IDOT separately from this I-290 Study.

1.4 Project Need

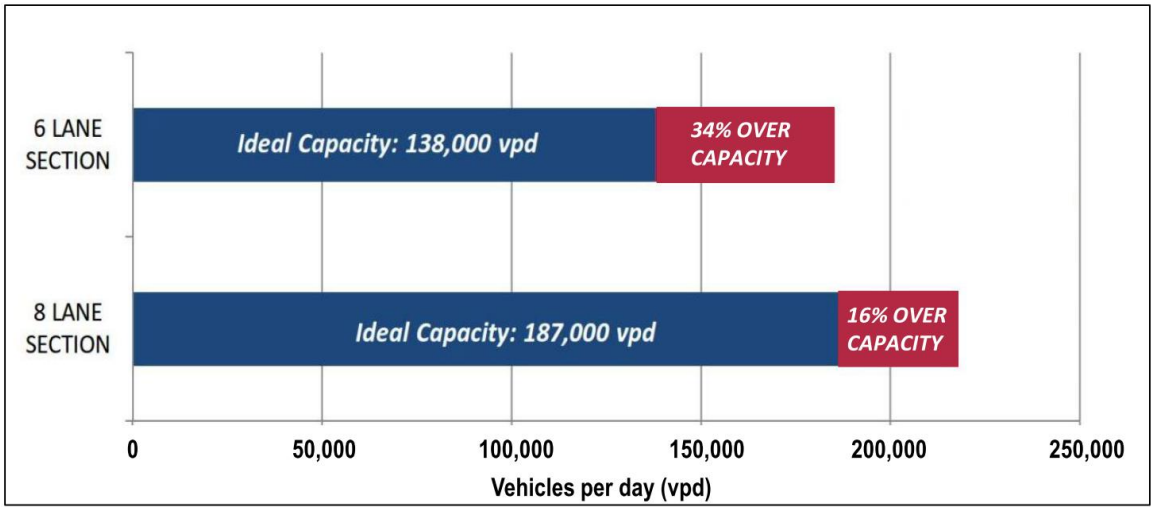
A transportation system improvement(s) is needed in the Study Area to address the following needs:

1. Regional and Local Travel;
2. Access to Employment;
3. Safety for All Users;
4. Modal Connections and Opportunities; and,
5. Transportation Facility Deficiencies.

These five principal needs or need points were identified in the technical analysis documented in the *Existing Transportation System Performance Report* (2010) and *Addenda* (2013)[1], and through stakeholder and public input.

1.4.1 Regional and Local Travel

This need point addresses the identified need to improve mobility, or the movement of people and goods, within the region and the Study Area. For this study, regional travel is considered as travel that begins and ends outside the Study Area. Local travel is travel that either begins, ends, or occurs entirely within the Study Area.



1.4.1.1 Regional Travel

No Build 2040
No Build (2040) traffic volumes represent a condition through year 2040 that includes all future planned and programmed infrastructure improvements, except this I-290 project. In other words, as if this I-290 project is not built.

There is substantial travel and congestion in the Study Area that reduces the corridor's ability to serve regional travel (Figure 1-3). One of the primary factors contributing to congestion in the corridor is that traffic demand exceeds the capacity on I-290. I-290 generally carries 185,100 to 217,700 vehicles per day (vpd), including approximately five percent trucks, on its six- and eight-lane freeway sections, respectively, according to 2012 traffic data. However, based on today's highway engineering standards, I-290 is ideally designed for 138,000 vpd for the six-lane section of the Study Area and 187,000 vpd for the eight-lane section of the Study Area for orderly traffic flow[2], and the existing mainline traffic exceeds its ideal capacity by 34 percent in the six-lane section and 16 percent in the eight-lane section (Figure 1-3). Estimated year 2040 No Build traffic on I-290 is projected to increase by an average of seven percent over the existing traffic volumes. This forecasted increase in traffic reflects the lack of available capacity on I-290 to accommodate additional traffic, the fully developed land uses and transportation network throughout the

[1] http://eisenhowerexpressway.com/info_center/reports.aspx.
[2] From *2000 Highway Capacity Manual,* Exhibit 13-6 using volume at 10 percent of average daily traffic (ADT) at LOS E.

Figure 1-3. Existing I-290 Capacity

Source: WSP Parsons Brinckerhoff, 2015.

corridor, and the additional capacity of the I-290/I-90/I-94 Jane Byrne Interchange, which is scheduled for completion in 2018.

Peak period travel speeds in the six-lane section of the Study Area are estimated to be as low as 24 miles per hour (mph) in 2010, and they are projected to slow down to as low as 12 mph for the 2040 No Build scenario. Estimated average peak period traffic speeds in the eight-lane section are projected to remain unchanged at 35 mph in 2040 for the No Build scenario.

Much of the congestion in the eight-lane section occurs in the westbound direction, from Austin Boulevard and extending approximately 5 miles back toward the east[3]. This congestion is attributed to the high vehicular demand in the corridor and to the abrupt I-290 mainline lane reduction from four to three lanes where the left I-290 through lane becomes the westbound off-ramp to Austin Boulevard. Similar congestion is experienced by eastbound traffic where mainline lanes are reduced from four to three lanes at 25th Avenue.

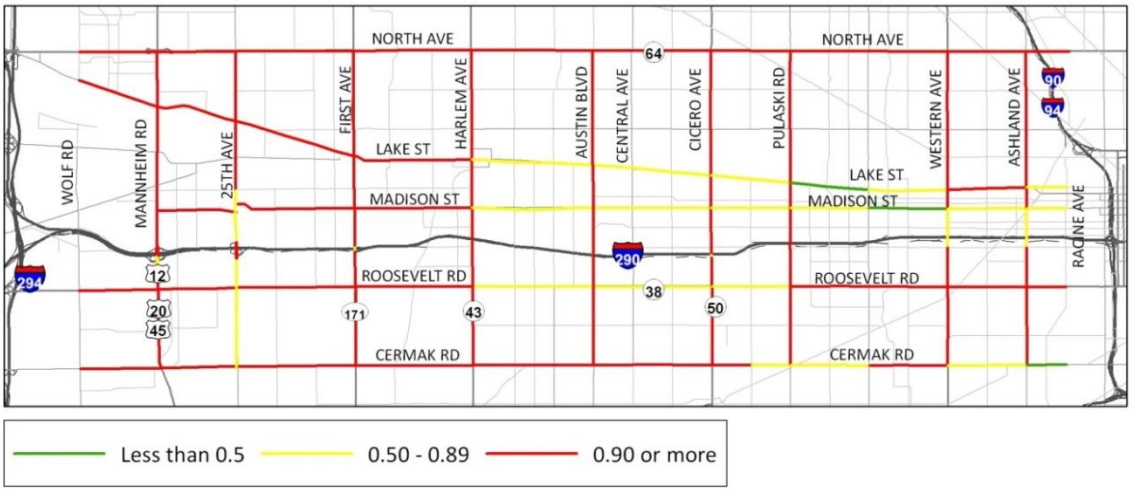
This severe traffic congestion on I-290 impacts regional travel for eastbound travel towards Chicago and Chicago's central business district, as well as for westbound travel heading towards the western suburbs in Cook and DuPage counties. This severe traffic congestion impacts through traffic, daily commuters, and commercial vehicles alike.

[3] Chicago Metropolitan Agency for Planning 2011 Congestion Scan http://www.cmap.illinois.gov/mobility/roads/cmp/performance-measurement/scans/i-290-eisenhower-expressway-canal-street-to-wolf-road.

1.4.1.2 Local Travel

Local travel, which is regarded as travel that either begins, ends, or occurs entirely within the Study Area, is negatively affected by mainline I-290 congestion, poor I-290 interchange operations, and congested arterial highways.

The I-290 interchange operations are negatively affected by the inability of vehicles to efficiently perform "movements" at the ramp/cross-street intersections. These movements include left turns, right turns, and through-intersection travel. When an interchange cannot adequately convey the traffic volumes at an intersection, the movements will become congested, cause backups, and begin to operate at very low levels of service (LOS). For arterial highways, IDOT policy indicates LOS D is acceptable in urban areas. Four out of five interchanges in the six-lane section of I-290 between 25th Avenue and Austin Boulevard currently have one or more movements that are failing (LOS E or F), compared to one out of the 11 interchanges in the eight-lane section of the Study Area. Factors affecting intersection operations include traffic demand exceeding design capacity, inadequate turn lane storage length, overburdened signal timing and phasing, and constrained intersection geometry.



Level of Service (LOS)
A qualitative system used to measure the effectiveness of a roadway to transport vehicles by comparing traffic counts, number of lanes, and functional classifications. The LOS system uses the letters A through F, with A being best and F being worst.

A = Free flow
B = Reasonably free flow
C = Stable flow
D = Approaching unstable flow
E = Unstable flow
F = Forced or breakdown flow

The I-290 mainline traffic congestion in the six-lane section causes traffic to divert to Study Area collector and arterial streets, placing additional burden on the local road network. The existing performance of east-west and north-south arterial streets in the Study Area was evaluated based on volume to capacity (v/c) ratios. In the v/c ratio, the volume, "v," is the number of vehicles using the roadway, and the capacity, "c," is the number of vehicles the roadway can accommodate just before breakdown occurs. When the volume of vehicles (v) on a street reaches its breakdown capacity (c), the ratio is equal to one, and when v/c ratio exceeds 1 (v/c > 1), operations become very unstable with closely spaced vehicles moving at slow, variable speeds. Minor disruptions within the traffic stream cannot be dissipated and result in operations that deteriorate to LOS F. Figure 1-4 illustrates the 2010 peak period v/c analysis for arterial streets, based on the I-290 existing conditions travel model results. In 2010, 80 percent of the Study Area east-west arterials corresponding to the six-lane expressway section operated at very congested conditions with v/c ratios greater than 0.90 corresponding to LOS E and F[4], compared with 47 percent of the east-west arterials at very congested conditions corresponding to the eight-lane section of the expressway.

[4] Transportation Research Board, *Highway Capacity Manual*, Special Report 209.

Figure 1-4. 2010 Existing Arterial Peak Period Volume to Capacity Ratios

Source: WSP Parsons Brinckerhoff, 2015.
Note: At v/c less than 0.5, the local road network can handle the traffic volumes. At v/c 0.50 to 0.89, the local road network is congested but can handle the traffic volumes. At v/c 0.90 or more, there are unstable, breakdown conditions, and the local road network cannot handle the traffic volumes.

1.4.2 Access to Employment

This need point addresses mobility for workers who reside in, work within, or travel through the Study Area, as well as the needs of regional employers. Traffic congestion on I-290 and the major arterial roads in the Study Area, and the inability to adequately accommodate additional traffic, limit the effectiveness of these transportation facilities to serve additional growth in the traditional commute (travelers heading inbound to Chicago from western and northwestern Cook, DuPage, and Kane counties during the morning peak period, and outbound from Chicago in the evening). The reverse commute (travelers heading outbound in the morning peak period and inbound in the evening peak) is also adversely affected, as are other smaller commuter travel markets. Traffic congestion on I-290 and parallel routes negatively impacts bus transit travel times and reliability, and the ability to make modal connections, as well as access to transit by automobile.

The Regional Transportation Authority's (RTA) *2005 Cook-DuPage Corridor Travel Market Analysis*[5], which evaluated the current travel market within and near the Study Area from Cicero Avenue on the east to DuPage County on the west, found that there are multiple options for traditional commuters who use the existing transit network and that they have access to the central business district and other destinations within Chicago via a combination of Metra commuter rail, CTA rapid transit and CTA/Pace bus. For the Cook-DuPage travel markets within the Study Area, 33 percent of traditional commute work trips use public transit. For the reverse commute, the *Cook-DuPage Corridor Travel Market Analysis* found that there are limited transit options to jobs in western Cook and eastern DuPage counties for workers in Cook County who live east

[5] *Cook-DuPage Corridor Travel Market Analysis Final Report,* Regional Transportation Authority with Cambridge Systematics, Inc., December 2005.

of Cicero Avenue. The RTA study found that reverse commuters come from areas with less automobile ownership than the Cook-DuPage region as a whole, and more reverse and other commute transit options are needed. For the Cook-DuPage travel markets within the Study Area, 15 percent of the reverse commute work trips use public transit. These percentages of public transit usage for traditional and reverse commute work trips are relatively higher than the five percent of work trips provided by public transportation in the US, and 11 percent of work trips provided by public transportation in the Chicago-Naperville-Joliet, IL-IN-WI Metropolitan Statistical Area, indicating relatively high percentages of commuters in the Study Area already using public transit.[6]

Heavy traffic congestion on I-290 and major arterial roads in the Study Area constrains connectivity to and from the Study Area in all directions (east-west and north-south). This results in longer travel times for highway trips from or to the Study Area, especially during peak periods, with traffic congestion worsening into the future. Job accessibility from the Study Area is depicted in Table 1-1. For example, using the 2010 highway network, there are 449,000 regional 2040 jobs[7] accessible within 15 to 30 minutes by automobile for a trip that begins from within the Study Area. Only 302,000 regional jobs would be accessible within 15 to 30 minutes for the 2040 No Build network, a decrease of approximately 33 percent. This decrease in regional job accessibility between 2010 and 2040 is due to growing traffic congestion resulting from the inability of the existing transportation system and planned improvements (excluding major improvements in the Project Corridor) to serve the projected travel demand.

Table 1-1. Regional 2040 Jobs Accessible by Auto from Study Area[8]

Auto Travel Time	Number of 2010 Network Jobs	Number of 2040 No Build Network Jobs	Percentage of Jobs Inaccessible by 2040
Up to 15 Minutes	107,000	79,000	-26%
15 – 30 Minutes	449,000	302,000	-33%
30 – 45 minutes	1,601,000	1,391,000	-13%
45 – 60 Minutes	1,760,000	1,613,000	-8%

Source: WSP Parsons Brinckerhoff, 2015.

[6] *Commuting in the United States: 2009, American Community Survey Reports, ACS-15*. US Census Bureau, Washington, D.C.

[7] "Regional 2040 Jobs" are job destinations projected to be in place by 2040. Access to these job destinations is projected using both the existing 2010 network and the 2040 No Build network to demonstrate that job accessibility from the Study Area will be reduced by 2040, even with planned regional transportation improvements, excluding major transportation improvements in the Study Area.

[8] A location near the center of the Study Area was used for this analysis.

Transit travel time to jobs includes in-vehicle (travel in the rail or bus vehicle) and out-of-vehicle travel time (access time, wait times, egress times). Job accessibility from the Study Area via transit is depicted in Table 1-2. As seen in this table, there is very little change between 2010 and 2040 (less than one percent) in accessibility from the Study Area to work opportunities in the region for transit trips under 45 minutes. This can be attributed to the majority of the CTA rail and bus service in the greater I-290 corridor remaining stable between 2010 and 2040. However, for transit trips between 45 and 60 minutes, a 12 percent increase between 2010 and 2040 in the number of jobs accessible is forecasted, mainly due to the transit expansion projects identified in the Chicago Metropolitan Agency for Planning (CMAP) GO TO 2040 Comprehensive Regional Plan outside the Study Area.

Table 1-2. Regional 2040 Jobs Accessible by Transit from Study Area[9]

Transit Travel Time	Number of 2010 Network Jobs	Number of 2040 No Build Network Jobs	Percentage of Jobs Inaccessible by 2040
Up to 15 Minutes	4,000	4,000	0%
15 – 30 Minutes	57,000	57,000	0%
30 – 45 minutes	796,000	786,000	-1%
45 – 60 Minutes	477,000	534,000	12%

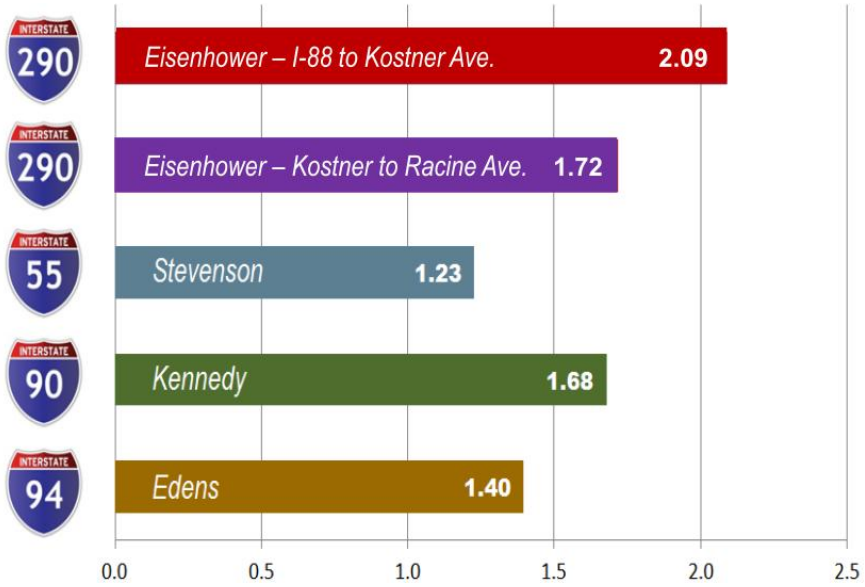
1.4.3 Safety for All Users

This need point addresses the frequency and severity of vehicular crashes in the Study Area and the conflicts between vehicles and pedestrians/bicyclists on facilities that accommodate these modes.

A crash analysis was initially performed for the 2006-2008 reporting period and then updated for the 2011-2013 reporting period, using data compiled by IDOT based on local and state police crash reports. For the 2011-2013 period, a total of 5,365 crashes and 711 injuries were reported along I-290, for an average of 1,788 crashes and 237 injuries per year. Crashes are categorized using the KABCO reporting system[10] as fatal (Type K); incapacitating injury (Type A); apparent but non-incapacitating injury (Type B); no apparent injury but a complaint of pain (Type C); or property damage only (Type O, also referred to as PDO).

The threshold for reporting property damage in Illinois was raised from $500 to $1,500 per crash in 2009. Overall, crash trends in the 2011-2013 period were similar to those in 2006-2008, with high crash locations and predominant types of crashes being similar. Recently available crash data from 2013-2015 was also analyzed to determine if crash trends were similar to the previous two reporting periods. As compared to the 2011-2013 period, overall crashes increased 12 percent but crashes involving an injury decreased by

[9] A location near the center of the Study Area was used for this analysis.



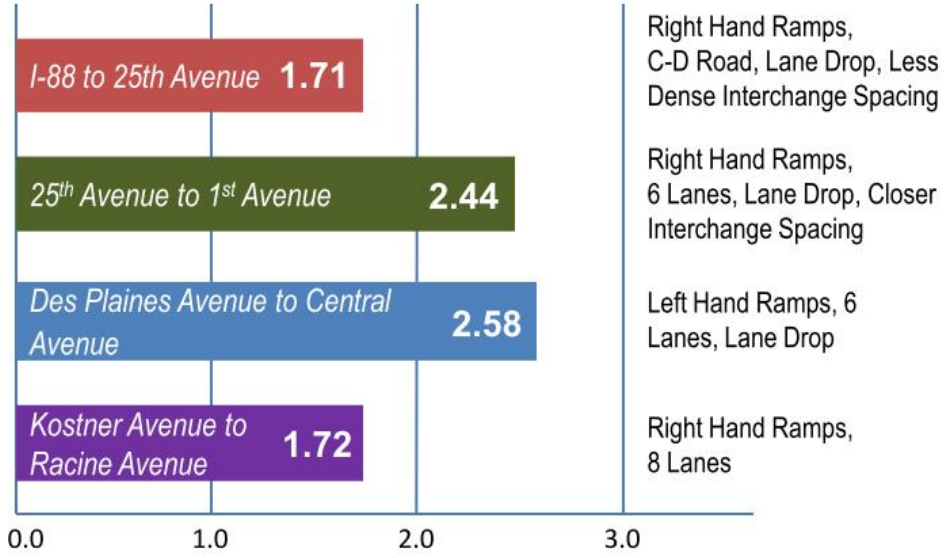
[10] *Manual on Classification of Motor Vehicle Traffic Accidents,* Seventh Edition, National Safety Council, 2007.

32 percent. These trends indicate that more crashes occurred at lower speeds in the 2013-2015 period as compared to the 2011-2013 period, with increased congestion being the primary contributing factor. A more detailed crash analysis, including the updated 2011-2013 and 2013-2015 crash information, is in Appendix A of this Final Environmental Impact Statement.

1.4.3.1 Crash Rate on I-290

Within the western part of the Study Area from I-294 to Kostner Avenue (including the six-lane section between 25th Avenue and Austin Boulevard), I-290 experiences crash rates that are 24 to 70 percent higher than comparable Chicago area freeways. Within the eight-lane section from Kostner Avenue to Racine Avenue in the eastern part of the Study Area, I-290 experienced crash rates that, while higher than other comparable freeways, were 21 percent lower than the western section. Figure 1-5 illustrates the comparison of crash rates for I-290 compared to other area expressways. As represented by Figure 1-5, I-290 in the eastern part of the Study Area does not experience the high rate of crashes of the western part of the Study Area. The overall crash rate of 1.72 crashes per million vehicle miles in the section of I-290 from Kostner Avenue to Racine Avenue is indicative of the less frequent crash occurrences within this section compared to the crash rate of 2.09 in the section of I-290 from I-294 to Kostner Avenue.

Figure 1-5. Comparison of Chicago Freeway Mainline Crash Rates (2006-2008, 2011-2013)[11]

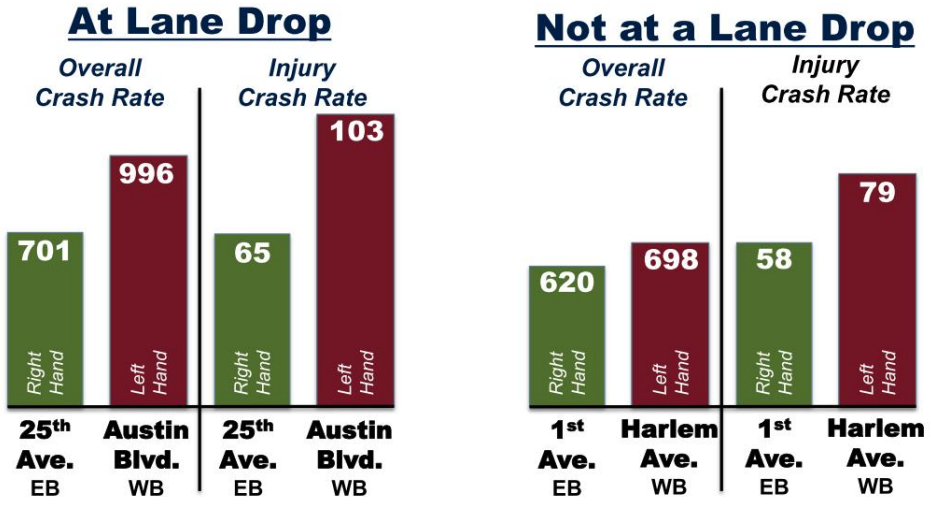


Source: WSP Parsons Brinckerhoff, 2015.
Note: Values Calculated as Crashes per Million Vehicle Miles

[11] 2009-2010 omitted. There was a major resurfacing on I-290 in 2010.

Within certain sections of I-290, there are variations in the crash experience based on the underlying characteristics of the roadway (Figure 1-6). For example, the eastern section between Kostner Avenue and Racine Avenue has eight travel lanes, conventional right-hand ramps, and less dense interchange and ramp spacing than the western section between 25th Avenue and 1st Avenue, and had a crash rate of 1.72 crashes per million vehicle miles in the combined 2006-2008 and 2011-2013 reporting periods. A higher crash section is located from 25th Avenue to 1st Avenue; this section has four interchanges in each direction located within a 1.5 mile distance, six travel lanes, and a lane drop from four to three lanes eastbound at 25th Avenue; this section has a crash rate of 2.44, which is higher than the average overall crash rate of I-290 from I-294 to Kostner Avenue. The section between DesPlaines Avenue and Central Avenue (which includes the Harlem Avenue and Austin Boulevard interchanges) has an even higher combined crash rate of 2.58; this section contains two interchanges with left-hand ramps, a lane drop from four to three lanes westbound at Austin Boulevard, and six travel lanes from DesPlaines Avenue to Austin Boulevard. The section between I-88 and 25th Avenue contains a lane drop from four to three lanes at 25th Avenue in the eastbound direction, but otherwise it is designed to modern standards; its crash rate is a relatively low 1.71 compared to other sections of I-290, but it is higher than the average rates of other area expressways.

Figure 1-6. Crash Comparison of I-290 Mainline Sections (2006-2008, 2011-2013)



Source: WSP Parsons Brinckerhoff, 2015.
Note: Values Calculated as Crashes per Million Vehicle Miles

In the sections with higher crash rates, the presence of lane drops, close interchange spacing, left-hand ramps, and/or less mainline lane capacity contributes to the higher crash experience of those sections.

Figure 1-7 further shows that the Austin Boulevard interchange, with both left-hand ramps and the westbound lane drop, has comparatively worse crash and injury rates than other interchanges (Harlem Avenue, 25th Avenue, and 1st Avenue) with only one or none of those features. Of the interchanges without a lane drop, 1st Avenue, with right-hand ramps, has comparatively lower crash and injury rates than Harlem Avenue, which has left-hand ramps.

Figure 1-7. Lane Drop/No Lane Drop and Left-Hand/Right-Hand Ramp Crash Comparison (2006-2008, 2011-2013)

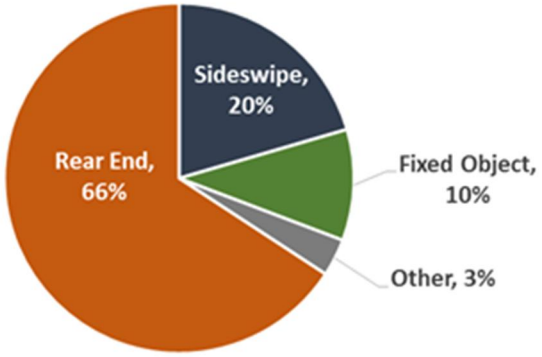
Source: WSP Parsons Brinckerhoff, 2015.
Note: Values Calculated as Crashes per Mile

1.4.3.2 Severity of Crashes

The overall predominant crash type along I-290 is rear-end (66 percent overall on a 24-hour basis) with 88 percent of rear-end crashes occurring during the peak period and midday congested travel periods between 6:00 a.m. and 11:00 a.m. (Figure 1-8 and Figure 1-9). During congested periods, rear-end collisions represent 75 percent of all crashes. National studies, as well as field observation of I-290 within the Study Area, indicate congestion as a primary cause of rear-end crashes due to erratic, stop-and-go traffic conditions with reduced space (headway) between vehicles that requires increased driver attentiveness to react to those conditions.

The other two prevalent crash types on the I-290 mainline are same-direction sideswipe and fixed object collisions off the roadway, which represent approximately 20 and 10 percent of overall crashes, respectively. Many same-direction sideswipes occur in areas where there are numerous lane-changing and weaving movements, such as near entrance and exit ramps. Most of the same-direction sideswipes are also occurring during congested conditions.

Figure 1-8. Overall Crash Type (2006-2008, 2011-2013)



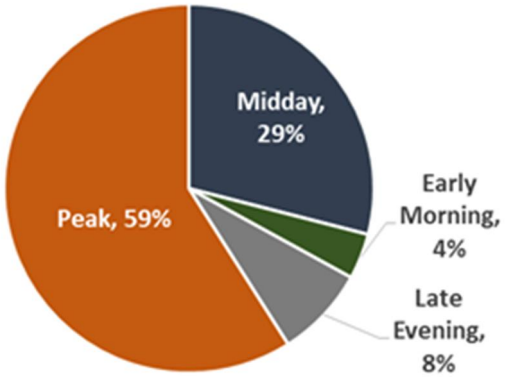


Figure 1-9. Rear-End Crash – Time of Day (2006-2008, 2011-2013)

Source: WSP Parsons Brinckerhoff, 2015.

For the western portion of the Study Area, there were eight fatal crashes and 37 incapacitating injury crashes on I-290 within the 2011-2013 reporting period; 56 percent of these severe crashes involved a rear-end collision, 11 percent involved a fixed object collision, and seven 7 percent involved a same direction sideswipe. A majority of the fatal and severe crashes in the six-lane section occurred during uncongested conditions.

For the eastern portion of the Study Area, there were five fatal crashes (Type K) and 17 incapacitating injury crashes (Type A) on I-290 within the 2011-2013 reporting period; of the severe accidents, 41 percent involved a rear-end collision, 28 percent involved a fixed object collision, and approximately 19 percent involved a sideswipe collision. A majority of the fatal and severe crashes occurred during uncongested conditions.

Overall, the western portion of I-290 within the Study Area experiences a 21 percent higher crash rate than the eastern portion. Crash types in the section are predominantly rear-end crashes that occur in congested conditions and where congestion occurs, clustered around closely spaced interchange ramps, left-hand ramps, and immediately upstream of the existing four- to three-lane expressway transitions.

1.4.4 Modal Connections and Opportunities

This point addresses the need to improve connections between all modes of transportation, including nonmotorized connections to transit, and improving the opportunities to better accommodate all transportation modes through cooperation and joint planning with municipalities and transit providers.

Transit
Transit for the I-290 project includes CTA rail rapid transit, Metra commuter rail, and CTA and PACE bus services.

The Study Area has a well-developed public transportation system that carries 21 percent of Study Area home-to-work travel, compared to 12 percent for the Chicago region overall. Although usage of the existing transit facilities within the Study Area is higher than for the region as a whole, these transit facilities, particularly with respect to

bus service and the Blue Line, do not operate at full capacity, and facility deficiencies hamper optimum provision of transit services.

1.4.4.1 Access to Transit

With the location of the existing CTA Blue Line stations within the median or adjacent to I-290, and the original design of many of the bridge structures that serve the station entrances dating to the 1950s, access deficiencies to the existing CTA Blue Line stations have been identified. These access deficiencies include all access modes, including pedestrian, bicycle, bus, and auto. The majority of existing Blue Line station entries are pedestrian trips. Pedestrian conflicts occur due in part to heavy traffic volumes and narrow sidewalks on the bridges that serve the station entrances (Figure 1-10). Bicycle access across I-290 is difficult due to lack of bicycle accommodations. Thus, nonmotorized access to existing CTA Blue Line stations is in need of improvement.

Figure 1-10. Narrow Sidewalks with Obstructions at Harlem and Oak Park Avenues

Bus transfer connections from CTA and Pace bus routes to the existing CTA Blue Line stations are located on the overpasses over I-290, except for the Forest Park station. The bus routes serving these stations, depending on their direction of travel, require pedestrians to cross to the opposite side of the bridge to reach these CTA Blue Line station entrances. Due to the lack of protected pedestrian crossings, transit users often jaywalk across two to four lanes of traffic during transfers between bus routes and Blue Line stations.

For auto access, the only CTA Blue Line park-and-ride facility in the Study Area is at the Forest Park terminal station, which operates at 85 percent capacity[12]. Access to the CTA and Village of Forest Park park-and-ride facilities is constricted by the congested traffic patterns at the I-290 DesPlaines Avenue interchange, with backups caused by traffic waiting to enter the westbound I-290 entrance ramp. The closely spaced traffic signals

[12] CTA Forest Park station parking utilization as reported by RTA (http://www.rtams.org/rtams/station.jsp?id=51100390).

on DesPlaines Avenue and left turns required for egress/ingress for Pace and CTA bus operations also results in delays to transit operations.

1.4.4.2 Nonmotorized Connections

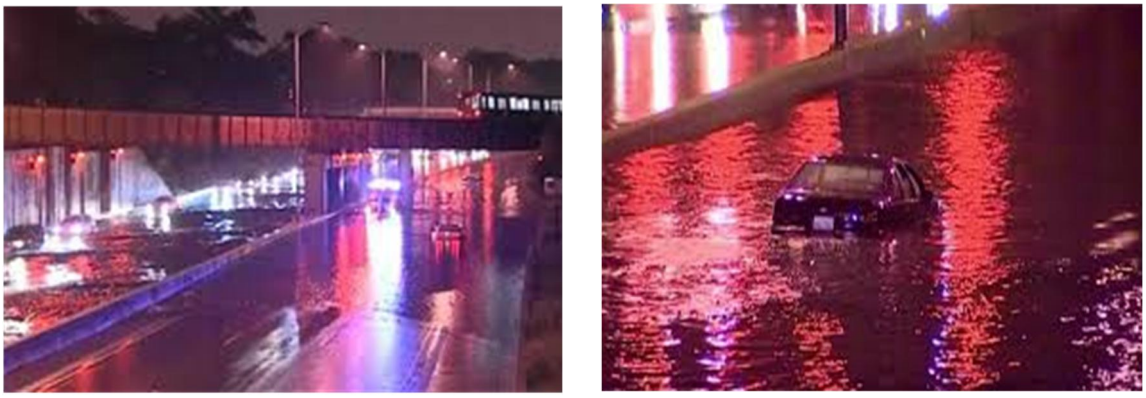
There is limited pedestrian and bicycle access within the Study Area. Between the west end of the Study Area and east of Cicero Avenue, there are only two pedestrian/bicycle dedicated crossings of I-290. In addition, five major street crossings of I-290 in this section (Wolf Road, Mannheim Road, 1st Avenue, DesPlaines Avenue, and Cicero Avenue) are designated "Not Recommended for Bicycle Travel" by IDOT's Bicycle Map, and the remainder of the I-290 street crossings in the six-lane section do not have bicycle accommodations that would provide safer, more comfortable operating zones for bicyclists, except for Ridgeland Avenue in Oak Park, which has marked shared bike lanes. In the eight-lane section from east of Cicero Avenue to Racine Avenue, designated bicycle/pedestrian crossings occur every mile, on average. These crossings are being examined as part of the previously mentioned IDOT bridge projects within the Extended Study Area.

Nonmotorized
Nonmotorized for the I-290 project includes pedestrian and bicycle facilities, such as sidewalks, trails, bike lanes, and bike racks.

1.4.4.3 Multimodal Opportunities

The *Cook-DuPage Corridor Study* and the *Existing Transportation System Performance Report* identified several opportunities for improving transit facilities and services in the Study Area. These opportunities included renewal of the existing rail and bus infrastructure in the Study Area, potential new transit services and transportation facilities to better serve the reverse commute, and more convenient direct access to jobs for Study Area residents. The I-290 Study has been coordinated with the transit agencies and other stakeholders in the planning of future transit opportunities for the purpose of accommodating future transit improvements within the footprint of this proposed project.

1.4.5 Transportation Facility Deficiencies



This final need point evaluates the following transportation facility deficiencies: 1) pavement and structure conditions; 2) the ability of the existing transportation system in meeting current design standards; 3) pedestrian, bicycle and transit facilities; and 4) the existing drainage system. Opened to traffic beginning in the mid to late 1950s, I-290 was designed and constructed according to early standards that were created prior to the interstate highway system. As such, the existing pavement and bridges are now more than 50 years old, exceeding their typical service life (approximately 30 years for pavement and 50 years for bridges). Regular cycles of maintenance and rehabilitation have been successful in extending the service life; however, maintenance cycles will become more frequent and do not address many of the underlying issues.

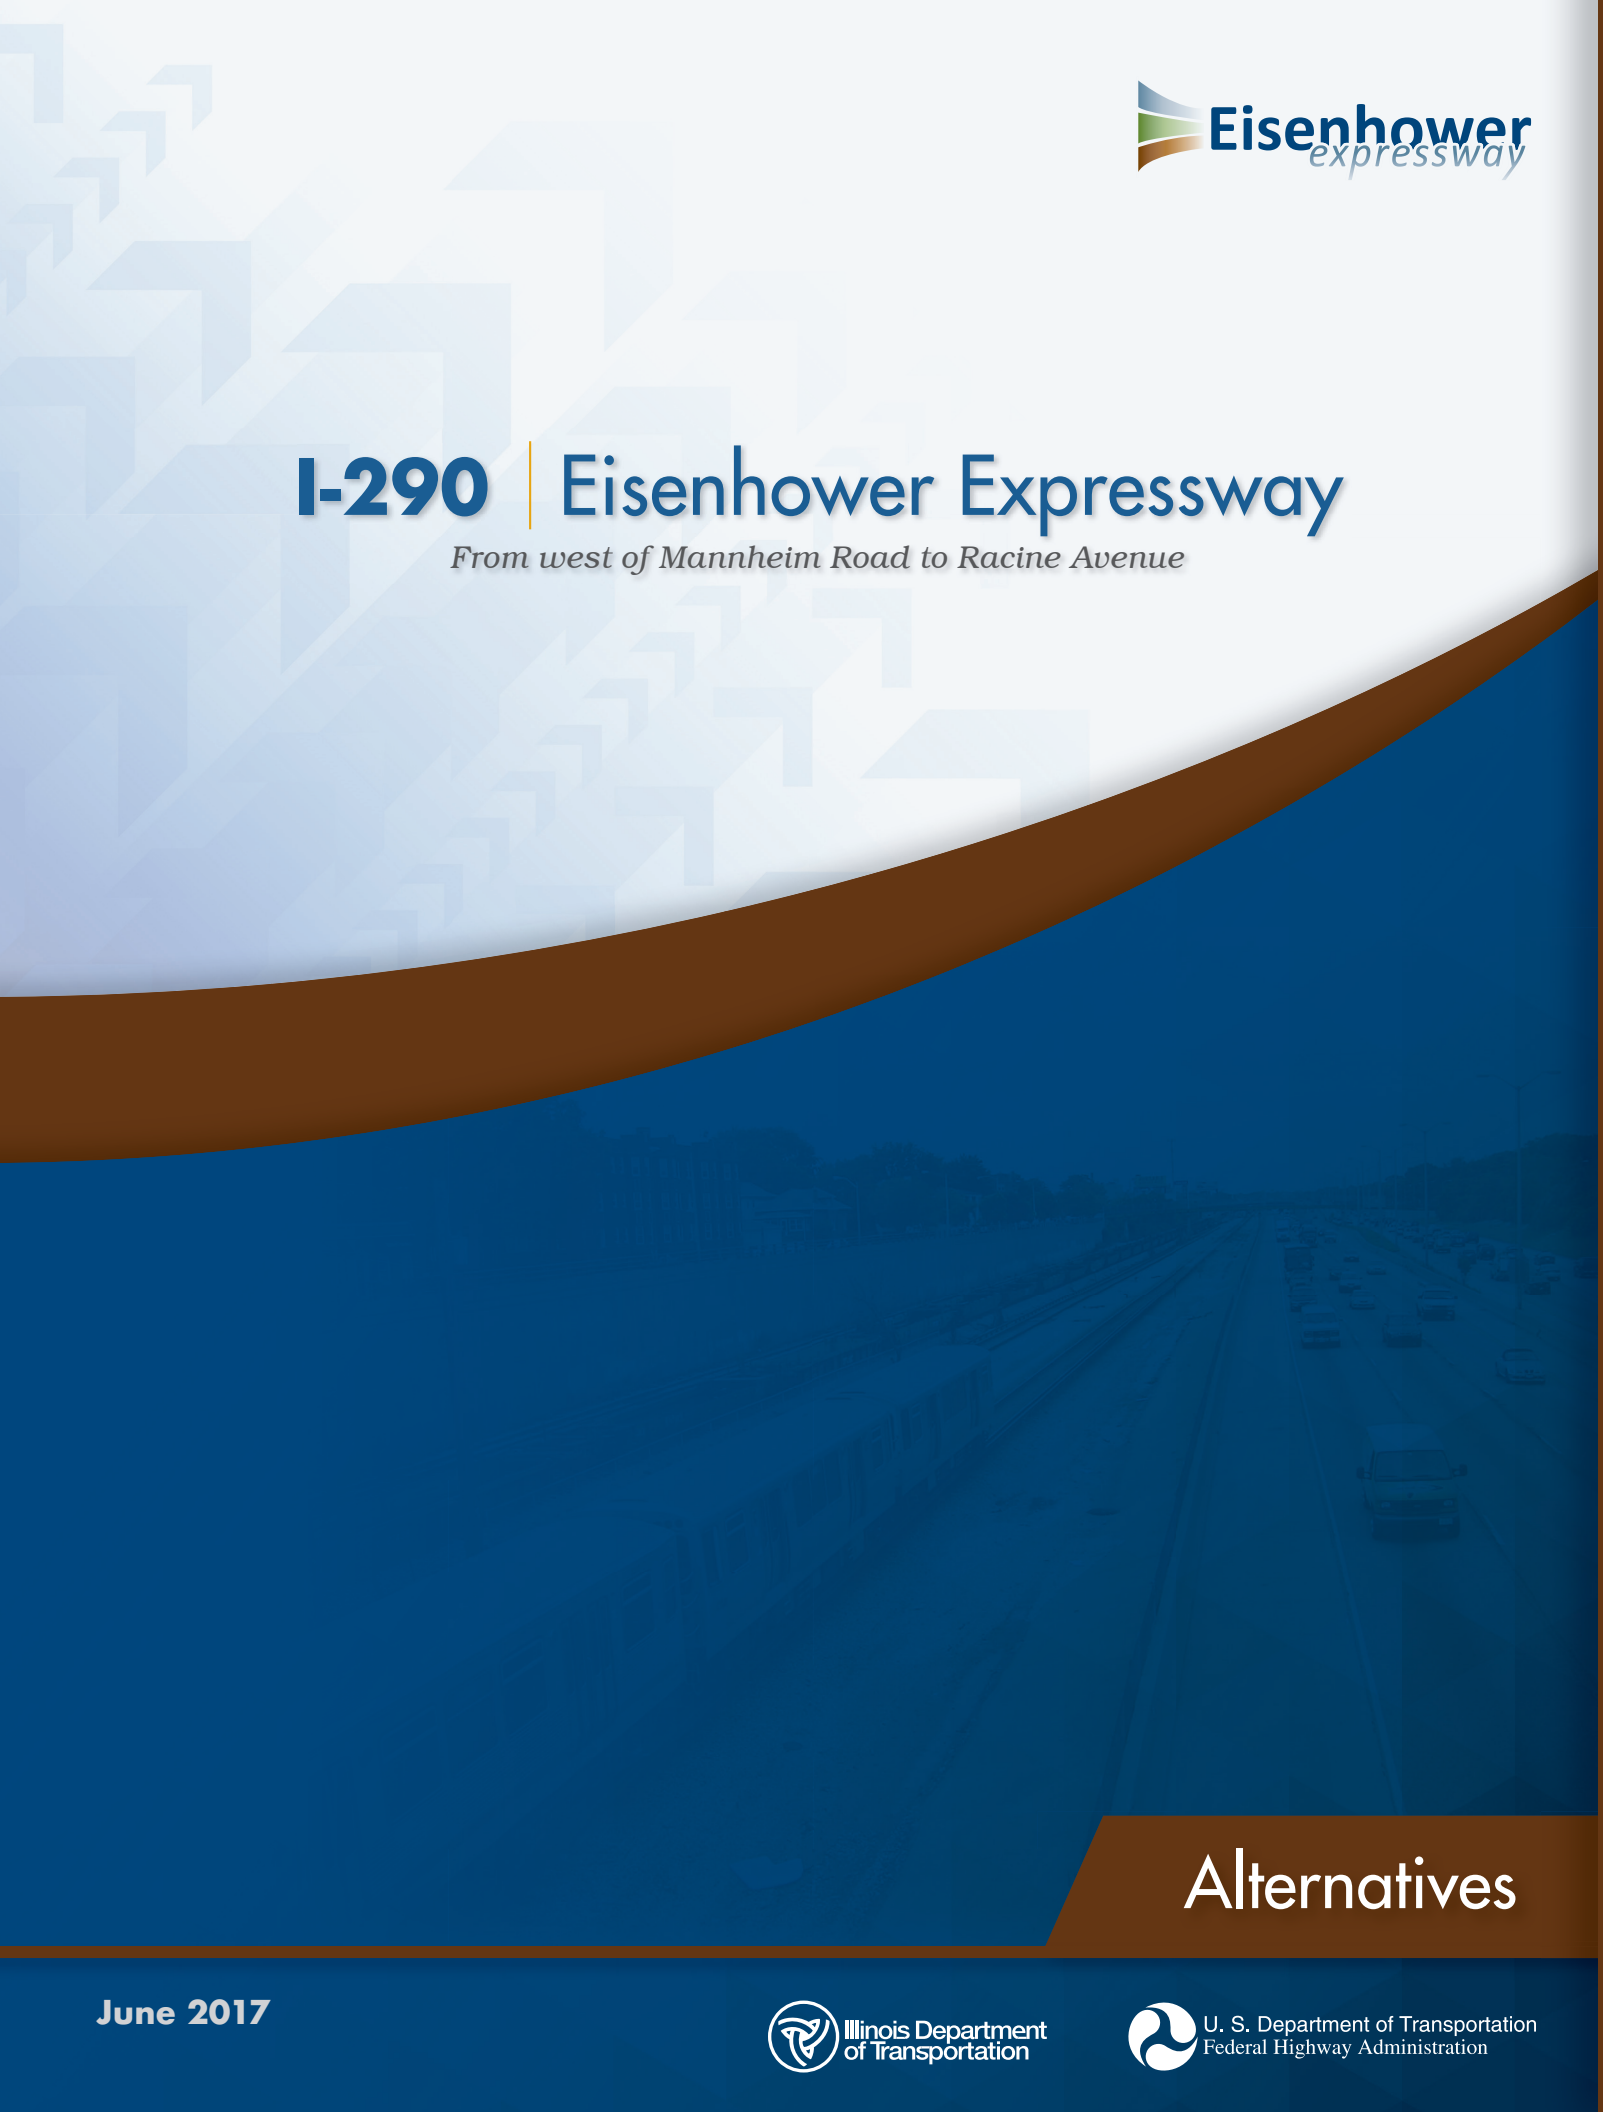
Most of the existing pavement structure on I-290 west of Cicero Avenue is original to the 1950s construction. Although the expressway was resurfaced with asphalt in 2010, more than 90 percent of the underlying existing Portland cement concrete pavement and sub-

base in the Study Area are now more than 50 years old, exceeding their typical service life by 30 years.

The drainage system, also installed in the 1950s, is in need of improvement. A detailed hydrologic evaluation of the trunk sewer in the six-lane section of the Study Area revealed that the I-290 pavement, which drainage was designed for a 10-year frequency storm, would be overtopped by a 100-year storm. This has now occurred in the July 2010, April 2013, and August 2014 storms that flooded the roadway and forced closures of I-290 and CTA rapid transit (Figure 1-11). The pump station located at the Des Plaines River is being replaced and expanded in advance of the overall I-290 reconstruction project.

Figure 1-11. Flooding on I-290 in the Study Area

Since the original construction of I-290, state and federal design standards for highways have been updated to provide better operations and improved safety. As such, many existing design elements do not meet current standards, including ramp entrance and exit departure angles and vertical curves, as well as interchange geometrics, including turning radii and complete street requirements.



Like the existing mainline pavement, almost all of the existing cross road structures are original to the 1950s construction. Due to rehabilitations and regular maintenance, all bridges in the Study Area west of Cicero Avenue are currently rated as structurally adequate; however, deterioration of the structures is resulting in more frequent maintenance cycles.

Having been constructed in the 1950s before the requirements of the Americans with Disabilities Act (ADA) were enacted, much of the original cross road construction that still exists in the Study Area does not meet ADA standards for sidewalk widths and pedestrian ramps. Improvements will meet ADA compliance, will accommodate high-traffic sidewalk widths, and will address pedestrian safety, especially for persons with disabilities.

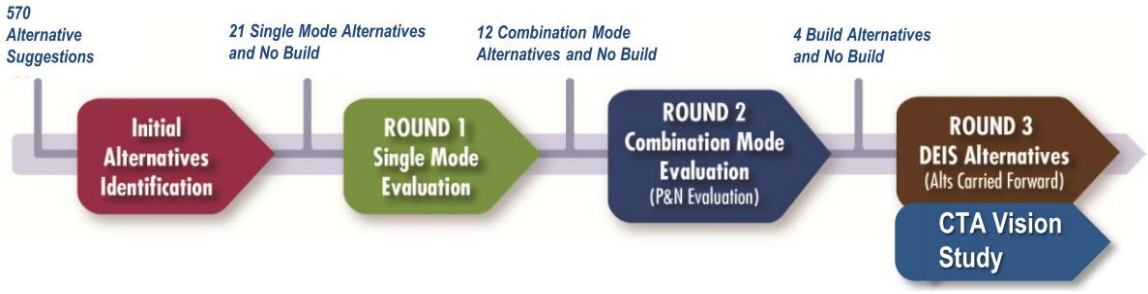
U. S. Department of Transportation
Federal Highway Administration



2.0 Alternatives

There have been no substantive changes to this section since publication of the DEIS.

2.1 Introduction

The process for developing and evaluating alternatives for the Interstate 290 (I-290) Eisenhower Expressway multimodal corridor consisted of four sequential steps, as shown in Figure 2-1.

Figure 2-1. Alternatives Development and Evaluation Process

Through these four consecutive steps, a wide range of alternatives were identified, evaluated, and screened, resulting in the identification of four build alternatives and the No Build Alternative to be carried forward into the Draft Environmental Impact Statement (DEIS) for more detailed evaluation. A range of factors was considered in the evaluation process, including how well the alternatives addressed the Purpose and Need (i.e., regional and local travel performance, access to employment, safety, modal connections and opportunities, and facility deficiencies), environmental constraints, displacements, and stakeholder input.

The process included a close examination of all transit modes within the Study Area, the results of which can provide input into future planning efforts by other area transportation agencies (e.g., Regional Transportation Authority [RTA], Chicago Transit Authority [CTA], Metra, Pace). In coordination with the Illinois Department of Transportation (IDOT) and the I-290 Phase I study, CTA initiated a concurrent *Blue Line Forest Park Branch Feasibility/Vision Study* to assess current conditions and identify modernization needs for rail infrastructure and customer amenities for the near- and long-term in this Project Corridor.

As presented herein, IDOT completed the evaluation of four build alternatives and the No Build Alternative. A regional travel demand model tailored specifically for this study was used as the evaluation tool for testing the travel performance of alternatives in Rounds 1, 2, and 3. This travel demand model is based on the Chicago Metropolitan Agency for Planning (CMAP) regional travel demand forecasting model. Several refinements were made to the CMAP model to incorporate additional existing transit

and roadway network detail, more recent travel data, and measures to better capture and evaluate the effects of carpooling, tolling, and transit. The travel demand model and its validation are described in Appendix B-1, Travel Forecasting Model Methodology and Validation.

Regional 2040 population and employment forecasts were developed as inputs to the travel demand model. These market-based forecasts were developed based on 2010 Census data, 90 years of historic population and employment data for the region, current and previous regional socioeconomic forecasts, land availability for development, population holding capacity, demographic data and trends (e.g., household size, migration patterns), local land use policies, and independent Woods & Poole economic forecasts. These forecasts are described in detail in Appendix B-2, Socioeconomic Forecast Report.

For Rounds 1 and 2, a 2040 baseline or No Build population and employment forecast was used as input in the travel demand model. The No Build forecast assumed no major capital improvements to I-290 or to the CTA Blue Line Forest Park Branch in the Study Area. This forecast represents the project's No Build Alternative, which is "alternative neutral" and is the baseline condition against which the transportation performance of alternatives is evaluated. A total of 33 alternatives (21 in Round 1 and 12 in Round 2) were evaluated with this forecast methodology. The number of alternatives evaluated in these rounds made socio-economic forecasting for each individual alternative impractical.

For Round 3, a 2040 Build population and employment forecast was developed assuming I-290 corridor improvements, including an additional lane on I-290 in each direction between Mannheim Road and Austin Boulevard. Appendix B-2 describes the market-based socioeconomic forecasts for the No Build and Build conditions.

Safety performance for Study Area arterials was analyzed based on methodologies prescribed in the American Association of State Highway and Transportation Officials (AASHTO) Highway Safety Manual (HSM). I-290 safety within the project limits was also assessed based on injury and fatal crash rates using statistically based predictive crash models developed by the Texas Transportation Institute (TTI), as the HSM did not have applicable expressway safety analysis tools at the time of the analysis. However, the TTI method has subsequently been adapted into the HSM's latest version.

2.2 Initial Alternatives Identification

This section describes the process that was used to identify the range of alternatives to be evaluated in Round 1. Section 2.2.1 presents the range of stakeholder suggestions, and Section 2.2.2 describes the prescreening process used to identify the set of alternatives to advance into the Round 1 screening process.

2.2.1 Initial Range of Stakeholder Suggestions

Alternatives suggestions for the I-290 Study were actively solicited from project stakeholders[1] and the public through public meetings, Corridor Advisory Group (CAG)/Task Force (TF) meetings, stakeholder meetings, and comments submitted via the project website, e-mails, and letters. Although all alternative suggestions were considered, single mode alternatives were sought for initial evaluation; single mode alternatives are those that use one mode of transportation (e.g., commuter rail, bus rapid transit [BRT], heavy rail transit [HRT], high occupancy vehicle [HOV] lanes, high occupancy toll [HOT] lanes) for the modification of, or addition to, the Study Area transportation network. The purpose of evaluating the single modes was to understand the characteristics of each individual mode and their effectiveness in addressing the transportation needs within the context of the Study Area.

Stakeholders are affected people and organizations, including federal, state, and local agency staff and elected officials, organized groups, area residents, and business owners.

Approximately 170 alternatives suggestions were submitted at the first public meeting (November 2009) and at the CAG/TF Alternatives Workshop in December 2010. Over 400 additional comments suggesting alternatives were submitted via the I-290 Study Website, subsequent CAG/TF meetings, and during the comment period for the second Public Meeting in May 2011. A total of 570 suggestions were submitted regarding alternatives. A comprehensive listing of the alternative suggestions is included in Appendix C.

A **Corridor Advisory Group** served as a regional steering committee that met over seven years during the I-290 Study process. The CAG focused on corridor-wide issues and collaboration. Membership consisted of representatives from each of the eight affected communities along the I-290 Corridor, plus regional planning agencies; CTA and PACE; and CSX Railroad, in addition to representatives from IDOT and Federal Highway Administration. (FHWA).

2.2.2 Single Mode Alternatives Identification

The alternative suggestions were sorted into three main groups: roadway improvements, transit improvements, and related improvements that could be combined with other concepts. Based on the range of stakeholder suggestions, each of the three groups was subdivided, resulting in 33 distinct concept subcategories (e.g., add general purpose lanes to I-290) to which each suggestion or comment was assigned. A functional description of each concept category can be found in Appendix C, which includes a table that describes how the 570 alternative suggestions were categorized.

[1] I-290 Eisenhower Expressway Phase 1 Study, Stakeholder Involvement Plan for Agency and Public Involvement, http://eisenhowerexpressway.com/pdfs/i290_stakeholderinvolvementplan_v5.pdf

A **Single Mode Alternative** is an individual transportation improvement that can be implemented independently as a stand-alone option apart from any other alternative.

After condensing the 570 alternatives into 33 concept categories, the 33 categories were prescreened to identify the single mode alternative concepts to be carried forward for evaluation in Round 1. Each concept was either: 1) carried forward into Round 1, 2) not carried forward into Round 1, or 3) deferred to a later round of evaluation. An important factor in the prescreening process was the potential to serve the two largest travel markets in the Study Area. The two largest travel markets, as identified by the RTA *Cook-DuPage Corridor Study Travel Market Analysis* (December 2005), are the traditional commute towards downtown Chicago and the reverse commute towards DuPage and northwest Cook counties. These two markets have the highest density of work trip origins and destinations. Concepts that had large right-of-way impacts on adjacent communities were not carried forward for further study. Other related improvements were deferred to future evaluation rounds.

Table 2-1 summarizes the results of the concept category prescreening process. A functional description and a detailed disposition for each concept category are shown in Appendix C.

Table 2-1. Summary of Prescreening Findings

Concept Categories	Concept Disposition		
	Carried Forward	Not Carried Forward	Deferred to Subsequent Rounds
Roadway Improvements			
A1. Add general purpose lanes to I-290	✓		
A2. Add HOV lanes to I-290	✓		
A3. Add HOT lanes in each direction	✓		
A4. Toll I-290 lanes	✓		
A5. Arterial widening	✓		
Transit Improvements			
B1. Extend CTA Blue Line to O'Hare International Airport		✓	
B2. Extend CTA Blue Line west	✓		
B3. Extend CTA Blue Line west via Illinois Prairie Path	✓		
B4. Add CTA Blue Line express service			✓
B5. Extend CTA Green Line to Maywood		✓	
B6. Add BRT via Prairie Path	✓		
B7. Add BRT along I-290	✓		
B8. Add BRT along east-west arterials		✓	
B9. Improve existing commuter rail		✓

Source: WSP Parsons Brinckerhoff, 2016.

Of the 33 original categories, 11 concept categories were carried forward for consideration in Round 1 evaluation. Eleven (11) concept categories of related improvements were deferred for consideration in subsequent evaluation steps (i.e., Rounds 2 or 3). Documentation of the reasons for carrying forward, not carrying forward, or deferring concept categories to subsequent evaluation is provided in Appendix C.

General purpose lanes (also referred to as "mixed use" or "mixed flow" lanes) are those where use is allowed by all vehicles (except certain small motorized vehicles, bicycles, and pedestrians on limited access highways), without restriction on number of occupants or imposition of a toll. All lanes on I-290 are currently general purpose.

Based on the 11 single mode concept categories carried forward from the prescreening, 21 single mode alternatives were developed by the project team and CAG/TF for evaluation in Round 1 and are summarized in Table 2-2 through Table 2-4. As seen in these tables, some of the concept categories resulted in multiple single mode alternatives. For example, three versions of the CTA Blue Line extension concept were carried forward as single mode alternatives with different project termini.

Table 2-2. Transit Modes Evaluated in Round 1

Blue Line Extension (Heavy Rail Transit - HRT) 	HRT 1	Forest Park CTA Terminal to Oak Brook via IL Prairie Path, Butterfield Road, and 22nd Street (elevated)
	HRT 2	Forest Park CTA Terminal to Oak Brook via I-290 median (at-grade) and parallel to I-88 (elevated)
	HRT 3	Forest Park CTA Terminal to Mannheim via I-290 median (at-grade)
Express Bus 	EXP	Various services from Forest Park CTA Terminal to DuPage and northwest Cook counties
Bus Rapid Transit (BRT) 	BRT 1	Forest Park CTA Terminal to Oak Brook via IL Prairie Path and Butterfield Road
	BRT 2	Forest Park CTA Terminal to Oak Brook via I-290 median (at-grade) and parallel to I-88 (elevated)
	BRT 3	Cicero Avenue to Oak Brook via I-290 median (at-grade) and parallel to I-88 (elevated)
	BRT 4	Ashland Avenue to Oak Brook with CTA Blue Line conversion to BRT from Ashland Avenue to Forest Park CTA Terminal, along I-290 median (at-grade) and parallel to I-88

HOT = High occupancy toll

Table 2-4. Arterial Improvements Evaluated in Round 1

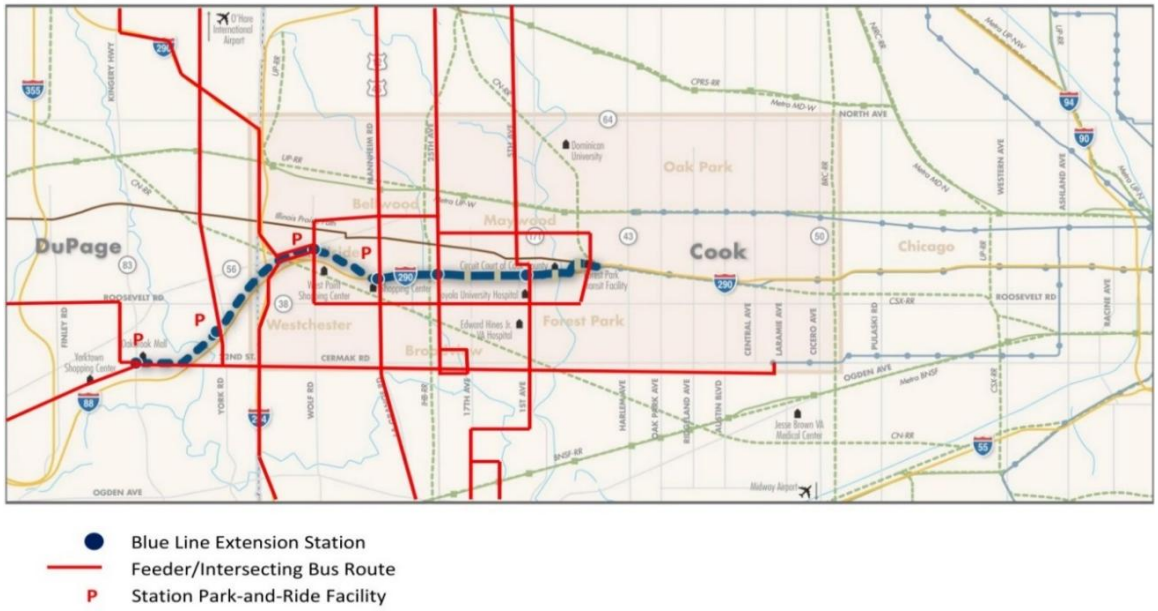
Arterial Widening	ART	Widening of Roosevelt Road and Madison Avenue to two continuous lanes in each direction (with and without parking) Roosevelt Road from I-294 to Cicero Avenue Madison Avenue from 25th Avenue to Cicero Avenue

Source: WSP Parsons Brinckerhoff, 2016.

The HOV and HOT alternatives assumed that two existing general purpose lanes (one in each direction) would be converted to HOV/HOT lanes along I-88 and along I-290 from Central Avenue to Racine Avenue. Along I-290 from the I-88/290 split to Central Avenue, two new HOV/HOT lanes (one in each direction) would be added to the existing lanes. Appendix C includes a set of maps representing the single mode alternatives listed above.

In addition, the No Build Alternative was included.

2.3 Round 1 Single Mode Alternatives Evaluation



This section describes the results of the Round 1 screening evaluation. Section 2.3.1 describes the definition of the single mode alternatives identified for Round 1 evaluation, Section 2.3.2 summarizes the footprint and fatal flaw analysis results, Section 2.3.3 summarizes the results of the Round 1 evaluation, and Section 2.3.4 describes the combination modes for evaluation in Round 2.

2.3.1 Single Mode Alternatives Definition

Twenty-one (21) single mode alternatives and the No Build Alternative were further defined and evaluated in Round 1. This included the conceptual alignments and layouts of the single mode alternatives and the definition of operational characteristics to be coded in the computerized transportation network for testing with the travel demand model. For the HRT and BRT alternatives that extended west beyond the existing CTA Forest Park Terminal, new stations were assumed along the extended route at 1st Avenue, 25th Avenue, Mannheim Road, Wolf Road, York Road, Roosevelt Road (for Illinois Prairie Path alignments), and 22nd Street. Park-and-ride access was assumed at the Wolf Road, York Road, and 22nd Street stations. Feeder bus routes were also configured to serve the new stations, as shown in Figure 2-2.

For the expressway alternatives, the managed lane alternatives (HOV and HOT) assumed intermediate access and egress locations to and from the managed lane. Depending on the termini of the managed lane, intermediate access and egress locations included I-290/I-88, Mannheim Road, DesPlaines Avenue, Austin Boulevard, and Central Park Avenue. For those expressway alternatives that included tolled facilities, tolling was tested using $0.06 per mile, which was the average toll rate for the Illinois Tollway system at the time.

Figure 2-2. Transit Bus Network Assumptions

Source: WSP Parsons Brinckerhoff, 2016.

2.3.2 Footprint and Fatal Flaw Screening Results

Corridor-level right-of-way footprints were mapped and evaluated to determine if there were any potential impacts that would result in that alternative being fatally flawed due to magnitude of impact. For this initial evaluation, corridor-level footprints evaluated the impact of the main trunk of each alternative and did not include more detailed and undefined components such as interchanges, intersection improvements, or other localized components, such as park-and-ride lots, that will be considered in subsequent rounds of alternative development and refinement. The footprint, or width of the alternative, was based on common design standards for each transportation mode.

Screening was initiated to evaluate the physical impacts of an alternative, or footprint, within the Study Area based on right-of-way requirements. A geographic information system (GIS) level of analysis was used for the initial screening to assess impacts based on information available. Prior to the footprint screening, an environmental constraint workshop was held with project stakeholders at a CAG meeting in September 2010 (Appendix C) to identify potential footprint constraints along I-290. This workshop identified any area outside the existing expressway right-of-way as a constraint.

Corridor-level footprint impacts were then evaluated along any portion of an alignment that extended west of the Des Plaines River. West of the river, alternatives alignment locations were relatively straightforward, with fewer constraint variables affecting their locations. East of the Des Plaines River, all of the alternative alignments generally followed along the existing Project Corridor, with the exception of arterial improvements. None of the expressway alternatives were fatally flawed in Round 1 due to footprint impacts because they all stayed within the existing right-of-way.

For the transit alternatives, the conceptual alignments were either in the median of I-290, running on shoulders or other travel lanes, or elevated; consequently, none of the transit alternatives were fatally flawed in Round 1 due to footprint impacts.

The results of Round 1 footprint screening indicated that the arterial widening alternatives had a disproportionate number of displacements. Due to the very mature and dense urban environment along Roosevelt Road and Madison Street, arterial capacity improvements along these routes would involve widening (from two to four lanes where a two-lane section exists) between Mannheim Road and Cicero Avenue. This would result in 356 to 583 direct impacts to buildings (for widening without and with parallel parking, respectively). For this reason, arterial widening was dropped from further consideration in the alternatives evaluation. The summary table of these results and supporting evaluation exhibits can be found in Appendix C.

2.3.3 Round 1 Evaluation Results

Round 1 evaluated the transportation performance characteristics of each single mode prior to assembling combination mode alternatives in Round 2. Although Round 1 was not intended to be a test for consistency with the project's Purpose and Need, travel performance-based measures related to the Purpose and Need were developed and applied to evaluate the relative performance of the single mode alternatives with respect to the 2040 No Build condition. The performance measures assessed regional and local travel performance, such as vehicle and truck miles of travel, vehicle and truck hours of travel, congested vehicle miles of travel, hours of delay, I-290 and Study Area arterial speeds, travel times, and volume to capacity (v/c) ratios, and east-west Study Area person throughput measures. Accessibility from the Study Area to 2040 jobs was analyzed for both auto and transit modes in terms of the number of jobs accessible in a given time span from a central point in the Study Area.

Safety was also analyzed for I-290, arterials, and transit in the Study Area. Safety for the expressway and arterials was evaluated using the available quantitative safety assessment tools (TTI and HSM). Because no quantitative tool was available to evaluate transit safety, it was assumed that there were no injuries or fatalities for any trip using transit. Multimodal opportunities and connections were assessed for new regional transit trips. The facility condition was determined not to be a differentiator in the evaluation of alternatives in Round 1. As I-290 is in need of reconstruction due to uniformly poor facility conditions throughout the Project Corridor, this factor was evaluated consistently for all of the alternatives, including the No Build Alternative. The results of the Round 1 evaluation of the single mode alternatives are summarized in Table 2-5. As summarized in this table, the remaining nine transit and 11 expressway single mode alternatives were ranked as to how well their performance addressed the five main Purpose and Need points. For further detail, refer to the full results summary matrix for the single mode alternatives in Appendix C.

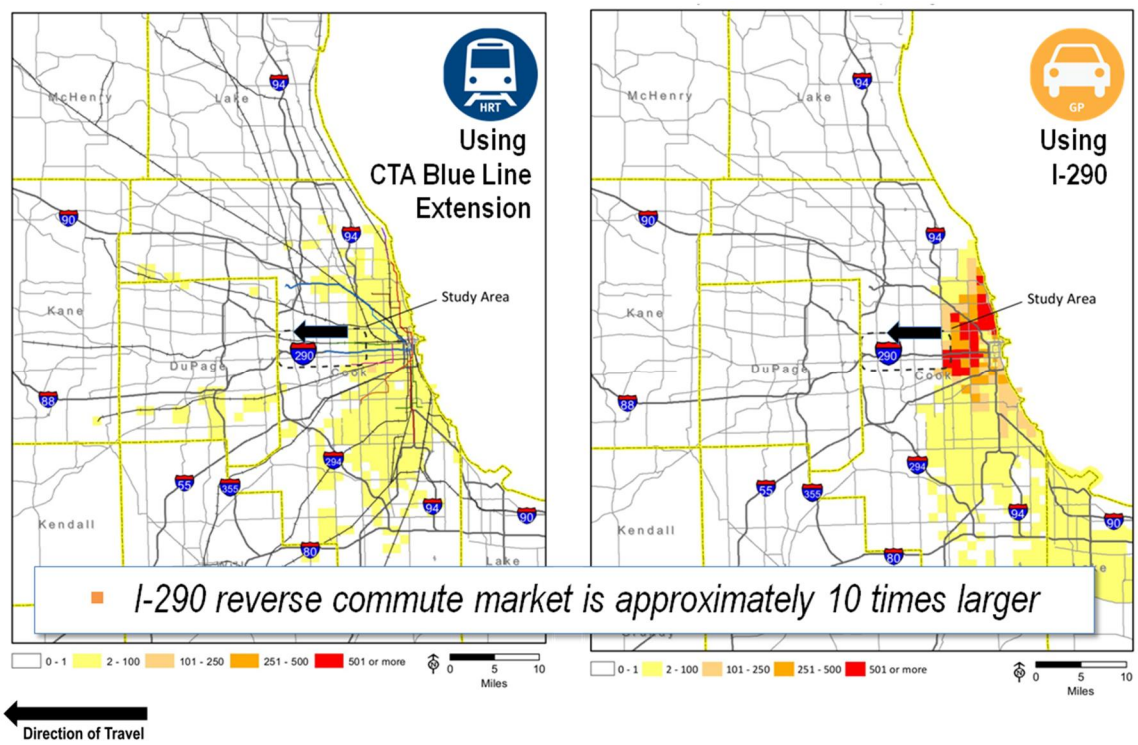
2.3.3.1 Round 1 Transit Mode Findings

The overall findings of the Round 1 evaluation of the single mode transit alternatives using the Regional Travel Demand Model are presented below.

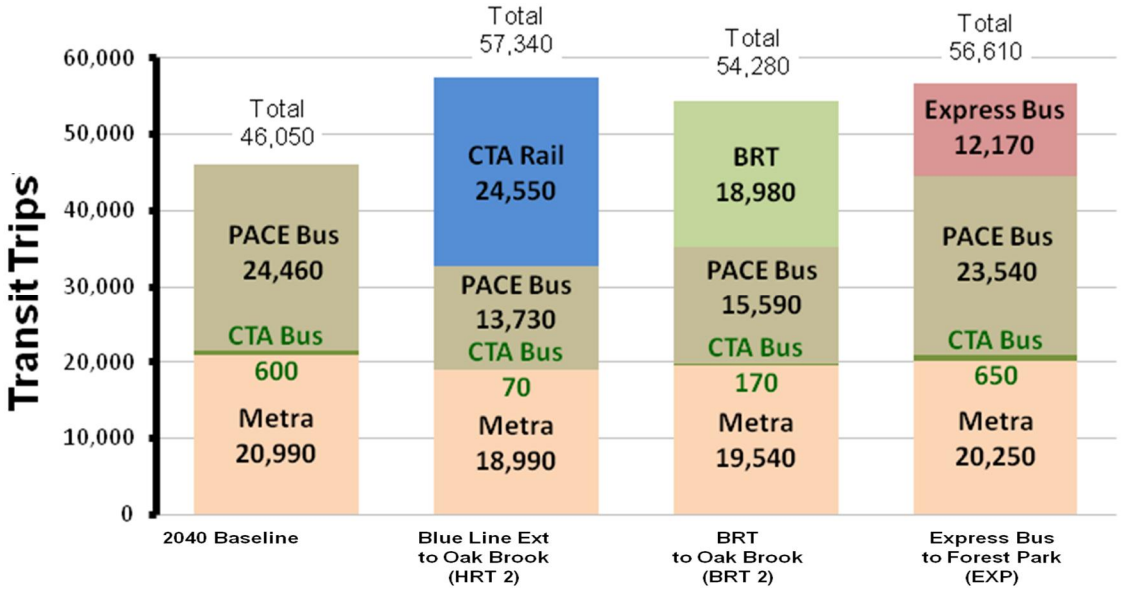


- The transit alternatives provide improved mobility options to areas west of the Forest Park Blue Line station, improved access to jobs, and some diversion of auto users.
- The transit alternatives did not result in any travel performance improvement to the I-290 Expressway. This is primarily due to insufficient diversion from auto to transit to have an impact on I-290 congestion. This is because transit serves a relatively small, compact market, as shown in Figure 2-3 and Figure 2-4. As seen in Figure 2-3 comparing the transit and expressway traditional commute travel markets (home-to-work), the transit travel market is much smaller and confined to an area immediately adjacent to the Blue Line extension compared to the travel market served by the I-290 Expressway, which has a much broader, more extensive draw of users that extends throughout DuPage County, and into Kane County and northwest Cook County. In the reverse commute direction, shown in Figure 2-4, the travel market for the Blue Line extension is broader, due to the extensive existing CTA network in the City of Chicago; however, the transit reverse commute travel market is much smaller than that of the I-290 Expressway at less than a tenth of the size.

Figure 2-3. Traditional Commute Travel Origins

Source: WSP Parsons Brinckerhoff, 2016.

Figure 2-4. Reverse Commute Travel Origins



Source: WSP Parsons Brinckerhoff, 2016.

- When comparing single mode transit alternatives, extensions of the existing CTA Blue Line Forest Park Branch with high-capacity transit modes of BRT and HRT showed the highest mode shifts from auto to transit and highest person throughput.
- There was a considerable amount of ridership drawn from other existing public transit services, and no single transit mode alternative was able to attract enough demand from automobile users to substantially reduce the demand on the expressway; therefore, single mode transit alternatives did not improve expressway performance.

For additional assessment and comparison of the transit alternatives, a screen line through the Study Area was evaluated between 1st Avenue and DesPlaines Avenue to compare to the east-west transit trips through the Study Area of three single mode transit alternatives to the baseline condition. As represented in Figure 2-5, approximately 46,000 daily transit trips on Pace and CTA buses and on Metra commuter rail trains cross through this screen line in the 2040 No Build condition. The Blue Line extension and BRT single mode alternatives to Oak Brook (HRT 2 and BRT 2) would result in diversions of up to 2,000 persons from Metra commuter rail and up to 11,000 passengers from Pace and CTA bus services. The ridership on the new BRT services and Blue Line extension would be between 19,000 and 25,000 riders, with a total transit screen line crossing of between 54,000 and 57,000 persons. Most of the ridership on the new transit service would be due to the diversion of trips from other existing transit services. For example, with the Blue Line extension to Oak Brook alternative (HRT 2)

Figure 2-5. Trip Diversions within Transit Modes

Source: WSP Parsons Brinckerhoff, 2016.

Pace Bus, CTA Bus, and Metra rail each would experience a reduction in ridership as a result of the CTA Rail extension. Although CTA Rail would attract 24,550 riders, 13,260 (54 percent) of these riders would be diverted from existing transit services (including 10,730 from PACE, 2,000 from Metra, and 530 from CTA bus). Of the overall increase in transit trips, 8,350 (34 percent) are diversions from auto, and the remaining 2,940 are new transit trips[2]. The diversion of 8,350 trips from auto to transit is small compared to nearly 250,000 weekday auto person trips that would remain on I-290. The other two single mode transit alternatives have similar results.

When comparing the effectiveness of the length of transit improvements, it was found that of the three Blue Line Extension alternatives evaluated (HRT 1, 2, and 3), most of the performance improvements were achieved by a Blue Line Extension to Mannheim Road (HRT 3), which is less than half the length of an extension to Oak Brook (3.5 miles versus 8 miles). Table 2-6 illustrates this comparison for several of the measures evaluated in Round 1.

As an example, the Blue Line Extension to Mannheim Road (HRT 3) provides 71 percent of the newly accessible jobs and 89 percent of new regional transit trips versus an extension to Oak Brook. Also, an HRT terminal west of Mannheim Road may serve as the starting point for a farther westward extension of the HRT line.

[2] I-290 Initial Alternatives Identification and Evaluation, April 2013.

Table 2-6. Performance Comparison of Blue Line Extensions

Performance Comparison* of Blue Line Extensions to:	Alignment Length	Daily Person Throughput	Regional Vehicle Miles Traveled	Regional Hours of Delay (Daily)	# of Jobs Accessible Increase	Overall Safety Improvements (Injury Crash Reductions)	New Transit Trips (Regional)
	Miles	# persons	Miles	Hours	# Jobs	Crash Rate	# trips
Oak Brook (HRT 2)	8	13,812	-37,362	-3,055	128,032	-3.37%	8,353
Mannheim Rd (HRT 3)	3.5	9,552	-35,438	-4,371	91,328	-2.25%	7,456
HRT 3 as % of HRT 2	44%	69%	95%	143%	71%	67%	89%

Source: WSP Parsons Brinckerhoff, 2016.
*From Round 1 single mode evaluation results.

Although not fatally flawed due to impacts, the Blue Line Extension and BRT Alternative along the Prairie Path (HRT 1 and BRT 1) are not being carried forward into Round 2 for further evaluation. The Blue Line extension and BRT alternatives along the Prairie Path and along I-290 (HRT 2) perform very similarly; however, the Prairie Path alignment has greater service overlap/duplication with the existing Metra service, and this alignment diverts more riders from the UP-West line than the alignment along I-290. There are also potential conflicts with the recreational functions of the Illinois Prairie Path corridor, which is considered Section 4(f). For these reasons, the alternatives using the Prairie Path alignment are not being carried forward for evaluation in Round 2.

The BRT 4 Alternative from Oak Brook to Ashland Avenue was evaluated as a conversion of the existing CTA Blue Line to a BRT facility between Ashland Avenue and the Forest Park terminal. This alternative indicated generally similar, and some improved, performance compared to an HRT Blue Line extension to Oak Brook (HRT 2); however, due to the similarity in performance and right-of-way requirements for these two fixed guideway transit facilities, the HRT extension of the Blue Line was selected as the representative mode that will be carried forward for evaluation in the combination alternatives.

2.3.3.2 Expressway Mode Findings

The overall findings of the Round 1 evaluation of the single mode expressway alternatives are presented below.

- Of all the single mode alternatives evaluated, the expressway alternatives showed the greatest improvement in travel performance for the region, in the Study Area, and on the I-290 Expressway itself. Due to the size of the travel markets the expressway is able to serve, there is a much higher demand for use of the expressway alternatives than for the transit alternatives. Of the expressway alternatives, the HOV and HOT lane alternatives had the best overall performance,

followed by the Toll and General Purpose lane alternatives. The HOV, HOT, and Toll lane alternatives also indicated that there would also be travel improvements for users of the general purpose lanes.

- The HOV and HOT lanes showed increased travel speeds over the existing general purpose lanes. Results of the Round 1 evaluation indicated that there was insufficient HOV 3+ Alternative demand (vehicles with three or more persons) to provide optimal peak-period performance.

The Round 1 single mode alternatives showing the best performance relative to the 2040 No Build condition are shown in Table 2-7.

Table 2-7. Single Mode Performance Ratings

Performance Summary	Top Performing Alternatives							
	1st	2nd		3rd	4th		5th	
Overall	 HOV 3LL	 TOLL 2	 HOT 2	 HOV 3+	 HOV 2LL	 GP LANE	 TOLL 1	 HOV 2W

Source: WSP Parsons Brinckerhoff, 2016.

Overall, managed lane expressway alternatives (HOV and HOT) provide some of the best performance benefits due to their ability to serve the high vehicle travel demand in this corridor, and they offer ways to more effectively manage the demand.

2.3.4 Initial Combination Mode Alternatives

Based on the findings of the Round 1 single mode alternative evaluation, 10 combination mode alternatives were assembled for evaluation in Round 2.

2.3.4.1 Expressway Modes in Combination Alternatives

Compared to the No Build condition, the stand-alone expressway alternatives resulted in the greatest improvement in travel performance for the region, Study Area, and along I-290, performing better than stand-alone transit modes for improving local and regional travel, overall access to employment, and safety. The top four expressway modes were selected for further testing in Round 2 as part of a combination mode alternative; GP Lanes, HOV 2+, TOLL, and HOT 3+. HOV with 2+ occupants was selected over HOV with 3+ occupants due to greater reduction in general purpose lane volumes and approximately twice the volume in the HOV lanes.

A fifth expressway alternative that pairs Toll Lanes and HOT 3+ was also identified to test the combined effects of converting I-290 to a tolled facility, with a HOT 3+ managed lane. These five expressway modes cover a range of potential expressway management strategies, from least amount of lane management (GP Lane Alternative) to a high level of lane management (TOLL & HOT 3+ Alternative).

To provide a consistent comparison basis between the Round 2 expressway alternatives, the eastern and western limits for each alternative were standardized to extend from the I-88/I-290 split at Wolf Road in the west to Racine Avenue in the east. These limits were established based on the Round 1 evaluation results, further clarification of tolling/ managed lane conversion legislation, and stakeholder input.

2.3.4.2 Transit Modes in Combination Alternatives

Although the stand-alone transit alternatives did not show the same level of improvements for expressway performance demonstrated by the expressway alternatives, they do offer additional benefits, such as increasing transit access to jobs, improving mobility for persons without auto access, and some auto person trip diversions to transit. To build on the performance improvements exhibited by the expressway alternatives and recognizing the additional benefits that transit provides, combination mode alternatives were developed to systematically test transit modes in combination with each expressway mode to determine if synergistic performance gains could be achieved.

Based on the Round 2 results, and coordination with transit agencies, two transit alternatives were identified for testing in combination with the expressway alternatives – Express Bus service (EXP) and a High Capacity Transit (HCT) extension to Mannheim Road.

EXP was included as a component in all combination mode alternatives due to its operational flexibility and physical compatibility with other modes. EXP would serve a broad market to the west, providing an express connection to the existing Blue Line Terminal in Forest Park or to a new HRT terminal at Mannheim Road. EXP may operate on the shoulder in the GP Add Lanes scenario, or in HOV, HOT, or Toll lanes, allowing this mode to integrate readily into the expressway alternatives.

The single mode transit system extensions evaluated from the existing Forest Park CTA Blue Line Terminal included HRT and BRT alternatives; each were found to be feasible with similar performance characteristics and footprint/right-of-way requirements. Since the HRT and BRT alternatives were found to be so similar in the Round 1 evaluation, the term “high capacity transit” was used going forward into Round 2, to include both the HRT and BRT modes.

The Mannheim Road terminus for an HCT extension was selected due to the single mode transit demand modeling results that suggested, relative to each other, most of the performance improvements were achieved by a Blue Line extension to Mannheim Road compared to an extension farther west to Oak Brook at less than half the length. Each Expressway and Express Bus transit combination alternative will be tested with and without HCT to Mannheim Road to systematically evaluate the effects of HCT in each scenario.

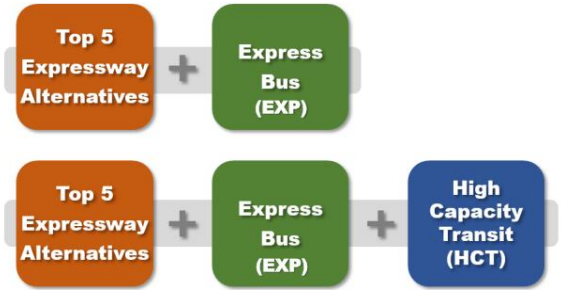
2.3.4.3 Initial Combination Mode Alternatives to be Evaluated in Round 2

Combination alternatives were then assembled to analyze the combined performance of transit and expressway alternatives in meeting the Purpose and Need. In addition, the compatibility of pairing each of the expressway modes with the transit alternatives was analyzed with regard to:

- Travel markets: To what degree do the expressway and transit components of these combination alternatives serve complementary or overlapping travel markets; and
- Operations: How well do the expressway and transit components of the combination alternatives work together from an operational perspective.

The rationale described above resulted in 10 initial combination alternatives, which are summarized in Figure 2-6. The top five highest performing expressway alternatives were first paired with the EXP single mode transit alternative to form the first five combination mode alternatives. Each of the five Expressway and Express Bus alternatives were then paired with the HCT extension from the Forest Park CTA Terminal to Mannheim Road to create the final five alternatives.

Figure 2-6. Initial 10 Combination Mode Alternatives



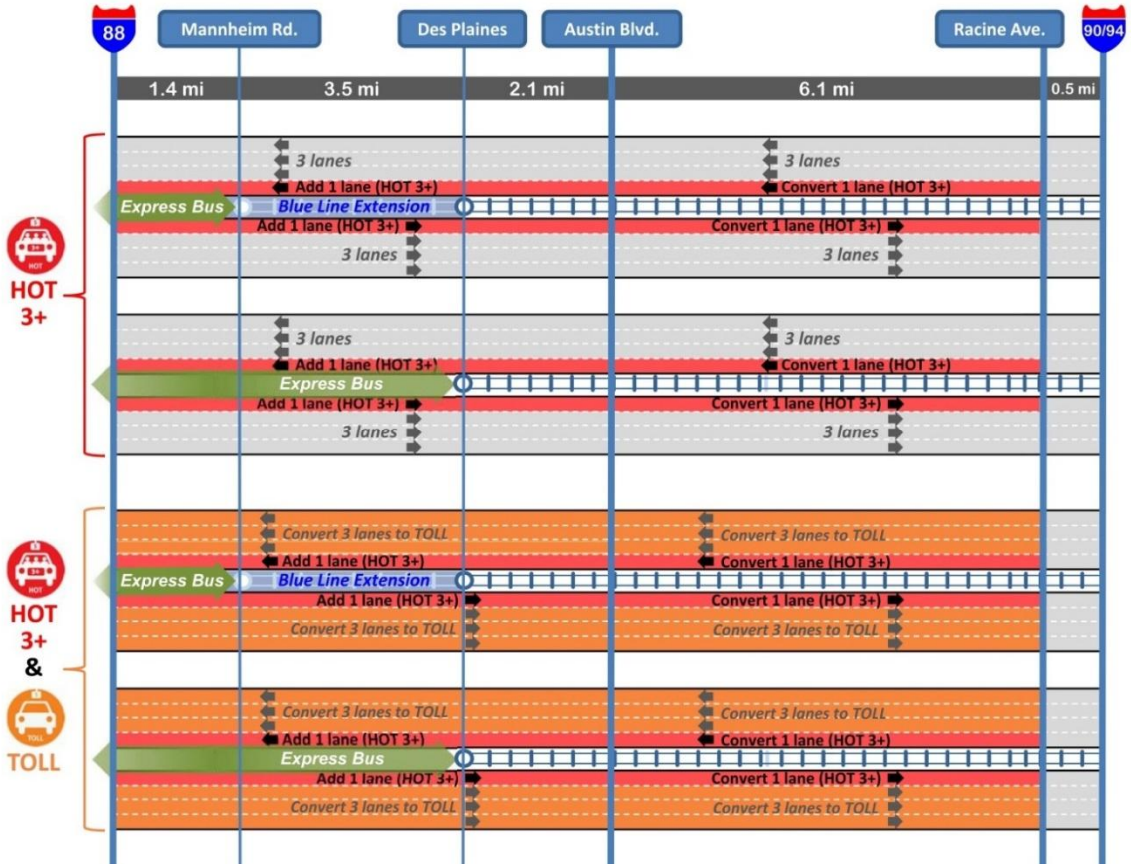


Figure 2-6. Initial 10 Combination Mode Alternatives (continued)

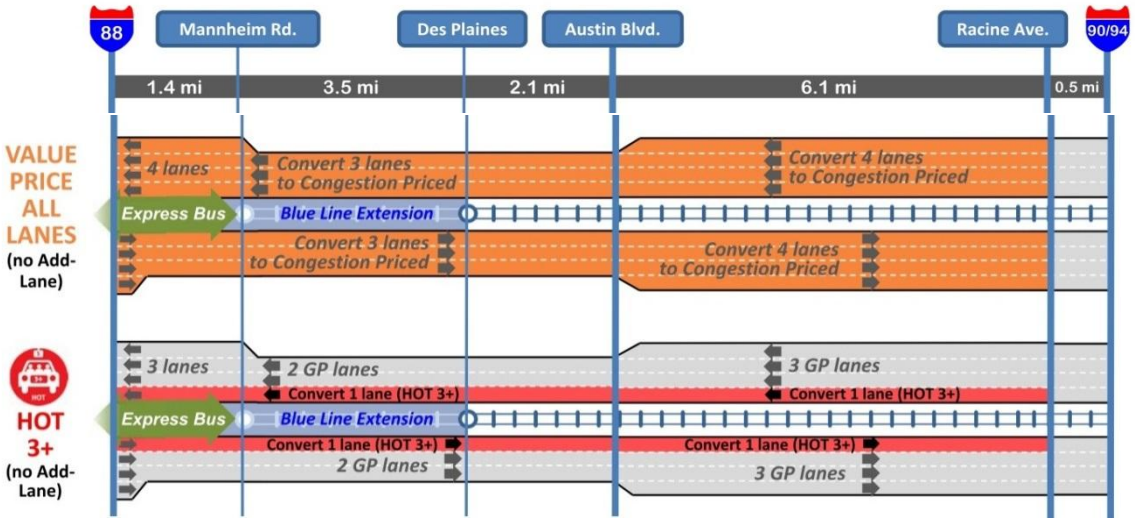
Source: WSP Parsons Brinckerhoff, 2016.



2.4 Round 2 Combination Mode Alternatives Evaluation

The results of the Round 2 screening evaluation of the combination mode alternatives are presented below. Section 2.4.1 presents the definition of the combination mode alternatives identified for Round 2 evaluation, Section 2.4.2 presents the results of the Round 2 evaluation, and Section 2.4.2.1 presents the mainline alternatives carried forward to Round 3.

2.4.1 Combination Mode Alternatives Definition

During the evaluation of the initial 10 combination mode alternatives, the CAG identified two additional combination mode alternatives for evaluation in Round 2 that combined transit and expressway management strategies, but without a lane addition in the existing six-lane section of I-290. The two additional alternatives that do not include a lane addition in the existing six-lane section are represented in Figure 2-7.

Figure 2-7. Additional Round 2 Combination Mode Alternatives

Source: WSP Parsons Brinckerhoff, 2016.

Table 2-8 provides more detailed descriptions of the Round 2 alternatives evaluated. In Round 2, service and operational characteristics of the alternatives were further defined for evaluation in the project's regional travel forecasting model. Model results were used to evaluate the performance measures in Round 2. General footprint variations of the combination mode alternatives were identified.

With regard to the service and operational characteristics of the 12 combination mode alternatives, the EXP component consists of three I-290 express bus services either continuing north on I-290 to serve the northwestern suburbs, heading west on I-88 to serve the western suburbs, or heading south on I-294 to serve the southwestern suburbs. The EXP components were included in all 12 alternatives and have two different termini, depending on whether an HCT extension is included in the combination mode alternative. In the five combination mode alternatives that do not include an HCT extension to the west, the EXP connects via I-290 to the existing Forest Park CTA Blue Line Station. For the seven combination mode alternatives that include an HCT extension to Mannheim Road, the EXP connects to a new CTA terminal located near Mannheim Road (and does not continue farther west along I-290).

For the purposes of evaluation with the regional travel model, the HCT extension was evaluated as an extension of the CTA Forest Park Blue Line rapid transit service; however, this service could be also run as BRT. Intermediate stations at 1st Avenue and 25th Avenue were assumed in each of the seven HCT extension alternatives. Park-and-ride availability was provided at a Mannheim Road terminal station. Feeder bus network assumptions were similar to those included in Figure 2-2, with the bus routes in DuPage County feeding the Mannheim Station.

Table 2-8. Combination Mode Alternatives Descriptions

GP Add Lane		**General Purpose Add Lane** from I-88 to Central Ave. with shoulder riding **Express Bus** from Forest Park to the west	GP Lane: • I-290 performance improvements • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with GP Lane (Bus on shoulder) HRT: • Auto diversions to transit • Job access improvement
		**General Purpose Add Lane** from I-88 to Central Avenue, **HRT** from Forest Park to Mannheim Rd., **Express Bus** from Mannheim Rd. to the west	
HOV 2+		**HOV 2+** from I-88 to Racine Ave., **Express Bus** operating in **HOV Lane** from Forest Park to the west	HOV Lane: • I-290 performance improvements • Manage added capacity • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with HOV Lane (Bus in HOV Lane) HRT: • Auto diversions to transit • Job access improvement
		**HOV 2+** from I-88 to Racine Ave., **HRT** from Forest Park to Mannheim Rd, **Express Bus** from Mannheim Rd. to the west

Source: WSP Parsons Brinckerhoff, 2016.

The 12 combination mode alternatives include maintaining the existing number of expressway lanes throughout and the addition of a new lane (in each direction) in the existing six-lane section of I-290 between I-88 and Central Avenue for 10 out of the 12 combination mode alternatives. For the managed lane concepts of HOV 2+, HOT 3+, TOLL, and HOT 3+ & TOLL, a conversion of one of the existing four lanes (in each direction) to a managed lane was assumed from Central Avenue to Racine Avenue. Racine Avenue was used as the eastern boundary of this lane conversion to allow sufficient traffic operational weaving distance between Racine Avenue and the ramps to I-90/I-94, and to match the Jane Byrne Interchange project's western terminus.

For those alternatives with a managed lane (HOV and HOT), intermediate access/egress for the managed lane was provided at 1st Avenue, Central Avenue, and California Avenue. For the HOT3+ and the TOLL alternatives, tolling at $0.12 per mile was assumed. The toll rate is consistent with what was used on the Illinois Tollway's I-355 South Extension, which was the most recent Tollway segment implemented at the time of the Round 1 screening in 2011. For the HOT3+ & TOLL and the BASE (2GP) & HOT3+ Alternatives, a toll rate of $0.16 per mile was assumed for the HOT3+ lane, and a toll rate of $0.12 per mile was assumed for the tolling of the general purpose lanes in each direction. For the BASE (3GP) W/ VALUE $ Alternative, toll rates of $0.25 per mile during the morning and afternoon peak periods (7:00 to 9:00 a.m. and 4:00 to 6:00 p.m.), $0.18 per mile during the peak shoulders (6:00 a.m. to 7:00 a.m., 9:00 a.m. to 10:00 a.m., 2:00 p.m. to 4:00 p.m., and 6:00 p.m. to 8:00 p.m.), and $0.12 per mile during the off-peak periods (10:00 a.m. to 2:00 p.m., and 8:00 p.m. to 6:00 a.m.) were assumed.

Within the 12 alternatives that were considered, three general footprint variations result: 1) an expressway lane addition with provision for an HCT extension in the median, 2) an expressway lane addition without the HCT extension provision, and 3) maintaining a six-lane section but including a provision for an HCT extension in the median. Detailed footprint requirements will be developed and evaluated in Round 3.

2.4.2 Round 2 Evaluation Results

For the Round 2 evaluation of the 12 combination mode alternatives, an evaluation matrix was used to summarize and compare how well the alternatives met four out of the five principal Purpose and Need points. The evaluation matrix for the combination mode alternatives included four of the five Purpose and Need point categories (referred to in this section as 'need points'):

- Improve Regional and Local Travel;
- Improve Access to Employment;
- Improve Safety for All Users; and
- Improve Modal Connections and Opportunities.

Because the expressway is in need of reconstruction regardless of the alternative, the fifth need point (Improve Facility Deficiencies) is common to all alternatives and is not a differentiator; therefore, it was not specifically measured in Round 2.

The evaluation measures used for **Improve Regional and Local Travel** were similar to those used in Round 1. These performance measures included assessing regional and local travel performance, such as vehicle and truck miles of travel, vehicle and truck hours of travel, congested vehicle miles of travel, hours of delay, I-290 and Study Area arterial speeds and travel times, and east-west Study Area person throughput measures.

Evaluation measures for **Improve Access to Employment** and **Improve Safety for All Users** are the same as those used in Round 1, which were the 2040 jobs accessible from the Study Area in a given time span for both auto and transit modes.

For the **Improve Modal Connections and Opportunities** need point, besides the new regional transit trip measure, two additional measures were included: 1) the number of households and 2) the number of jobs (employment) within 0.5 mile of a transit station, as compared to the No Build Alternative.

A scoring system was developed for Round 2. Across each of the 26 evaluation measures, alternatives were ranked from 1 to 12 (12 being the best), based on how well they performed relative to the 2040 No Build condition. Each alternative was then scored for each of the four need point categories by averaging the rankings of all the individual measures within the need point category. An overall score for each alternative was then calculated as the sum of the four need point category scores. With this scoring method, each need point category contributes equally to the overall score. The Rank Average for each need point was summed to arrive at the total, overall score for each alternative. For example, as shown in Figure 2-8, the "9.0" rank score for the HOV 2+ & EXP Alternative for Improve Safety for All Users was calculated by averaging the individual measure rankings (1 to 12) of the three travel measures for this alternative.

Figure 2-8. Alternative Ranking Example

Purpose and Need Point	Rank Average	
	HOV 2+ & EXP	HOV 2+ & EXP & HCT
Improve Regional And Local Travel	7.6	8.5
Improve Access to Employment	5.3	2.3
Improve Safety for All Users	9.0	10.0
Improve Modal Connections & Opportunities	1.0	6.7
Improve Facility Condition and Design	✓	✓
Score = Sum of Rank Averages	22.9	27.5

SAFETY	Injuries and Fatalities Rates % Change		Change from No-Build	Performance Rank (Compared to all alternatives)
	3.1	Arterial	0.08%	8
	3.2	Expressway	-10.14%	8
	3.3	Overall *(Arterial, Highway, Transit)*	-7.32%	11
		Need Point Average Rank ->		9.0

Source: WSP Parsons Brinckerhoff, 2016.

2.4.2.1 *Round 2 Screening Results*

The overall result of the Round 2 evaluation of the initial combination mode alternatives is presented in this section. In Figure 2-10 (Rank or Ordinal Scoring), the scores ranged from a high of 28.4 to a low of 17.9, with the largest gap in scores occurring between the top four and the remaining eight alternatives. The GP & EXP & HCT alternative had the highest overall score of all combination alternatives, followed by the HOV 2+ & EXP & HCT, HOT 3+ & EXP & HCT, and the HOT 3+ & TOLL & EXP & HCT Alternative.

At the request of stakeholders, a ratio scoring method was also applied. This method provides weighting for each measure based on the relative performance differences between the alternatives. Each of the 26 evaluation measures for each alternative was compared to the No Build Alternative and scored between 1 to 100 (1 being the worst, 100 being the best, and intermediate performers being scored on a proportionate basis). The alternative score is calculated based on its relative performance (or ratio) compared to the best (100) and worst (1) performer. Alternative scores for each need point were determined by averaging the scores of all the measures for that need point; the maximum score for any one need point is 100. For example, as shown in Figure 2-9, the "63.7" (Improve Safety for All Users) score for the HOV 2+ & EXP Alternative was calculated by averaging the individual performance scores (on a 1 to 100 scale) of the three measures for that need point. The total score for each alternative was then calculated by summing the four separate need point scores. As with the ranking scoring method, each need point contributes equally to the overall score.

Figure 2-9. Alternative Ranking Example (Ratio Scoring)

	Ratio Average	
Purpose and Need Point	**HOV 2+ & EXP**	**HOV 2+ & EXP & HCT**
Improve Regional and Local Travel	67.4	72.8
Improve Access to Employment	47.7	13.0
Improve Safety for All Users	63.7	74.3
Improve Modal Connections and Opportunities	0.0	83.3
Improve Facility Condition and Design	✓	✓
Score = Sum of Ratio Averages	**178.7**	**243.4**

SAFETY	Injuries and Fatalities Rates % Change		Change from No-Build	Performance Score (Compared to all alternatives)
	3.1	Arterial	0.08%	75
	3.2	Expressway	-10.14%	28
	3.3	Overall *(Arterial, Highway, Transit)*	-7.32%	88
		Need Point Ratio Score ->		**63.7**

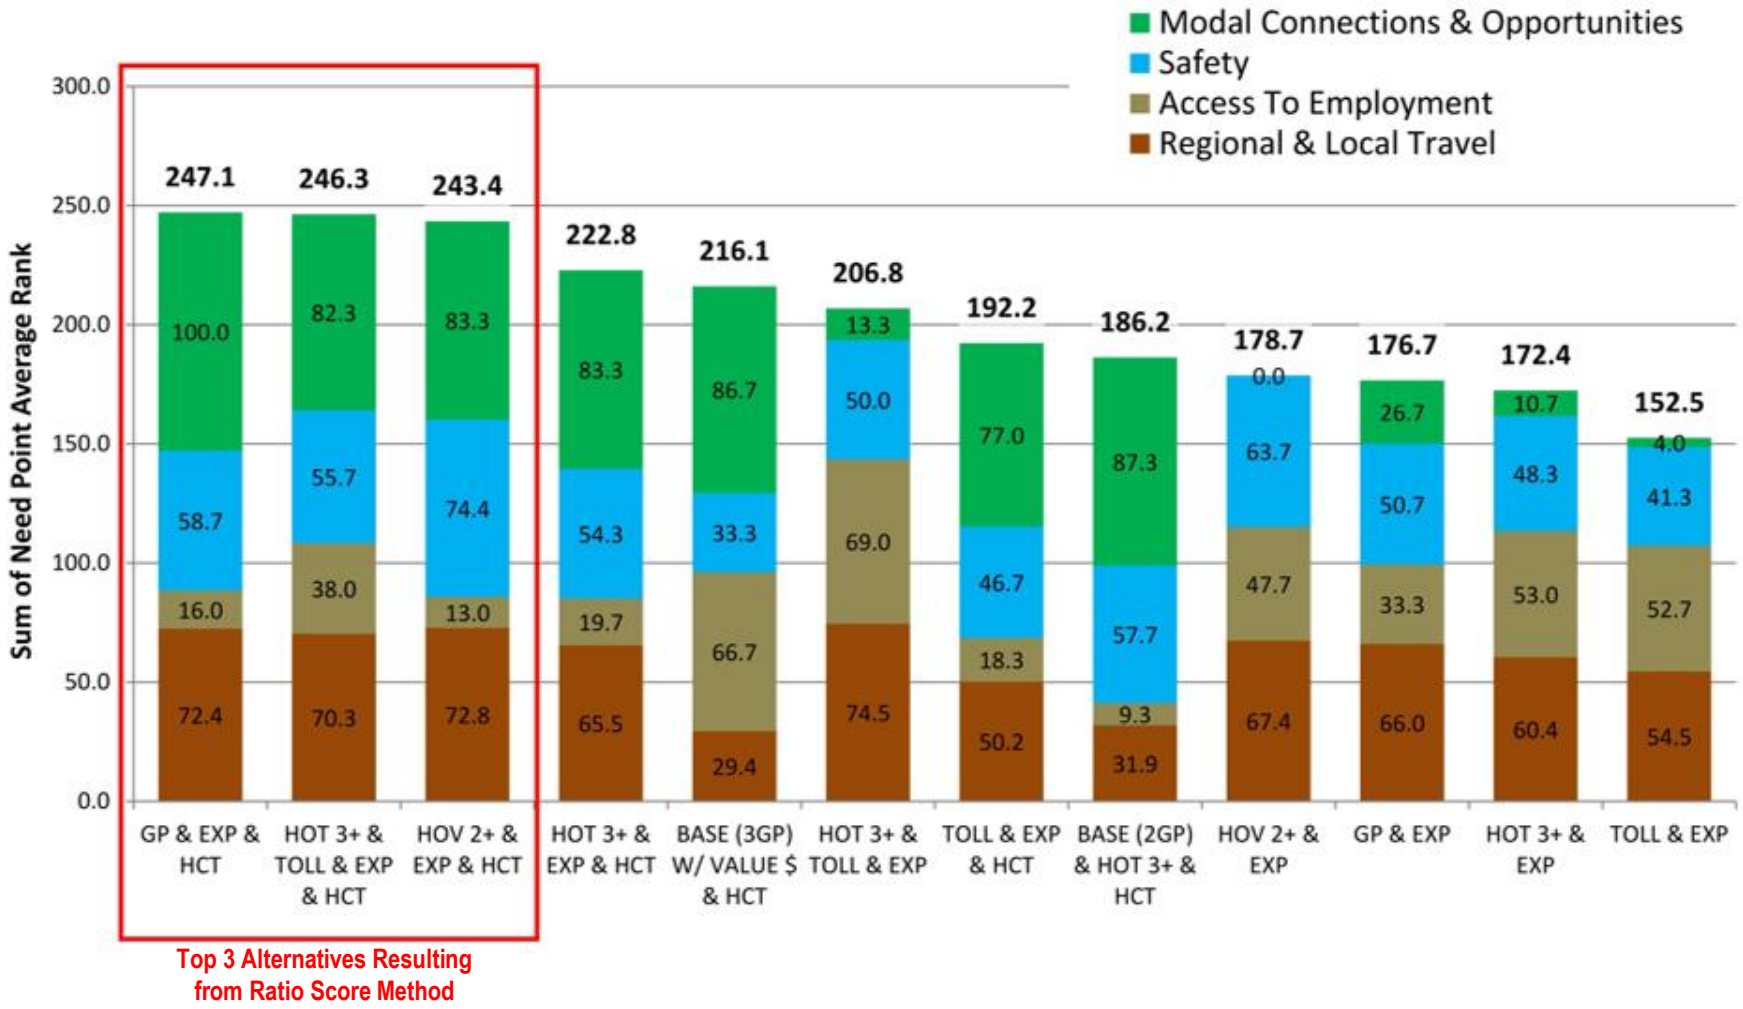
Figure 2-10. Round 2 Overall Alternatives Ranking

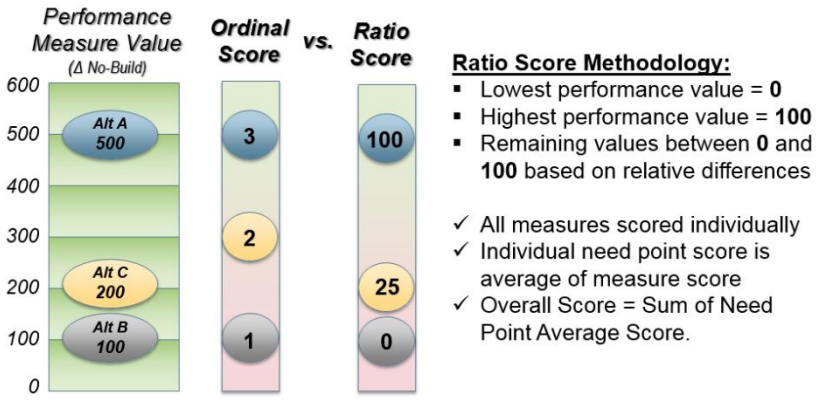


RANK (ORDINAL) SCORING

Source: WSP Parsons Brinckerhoff, 2016.

Figure 2-10. Round 2 Overall Alternatives Ranking (continued)

RATIO SCORING

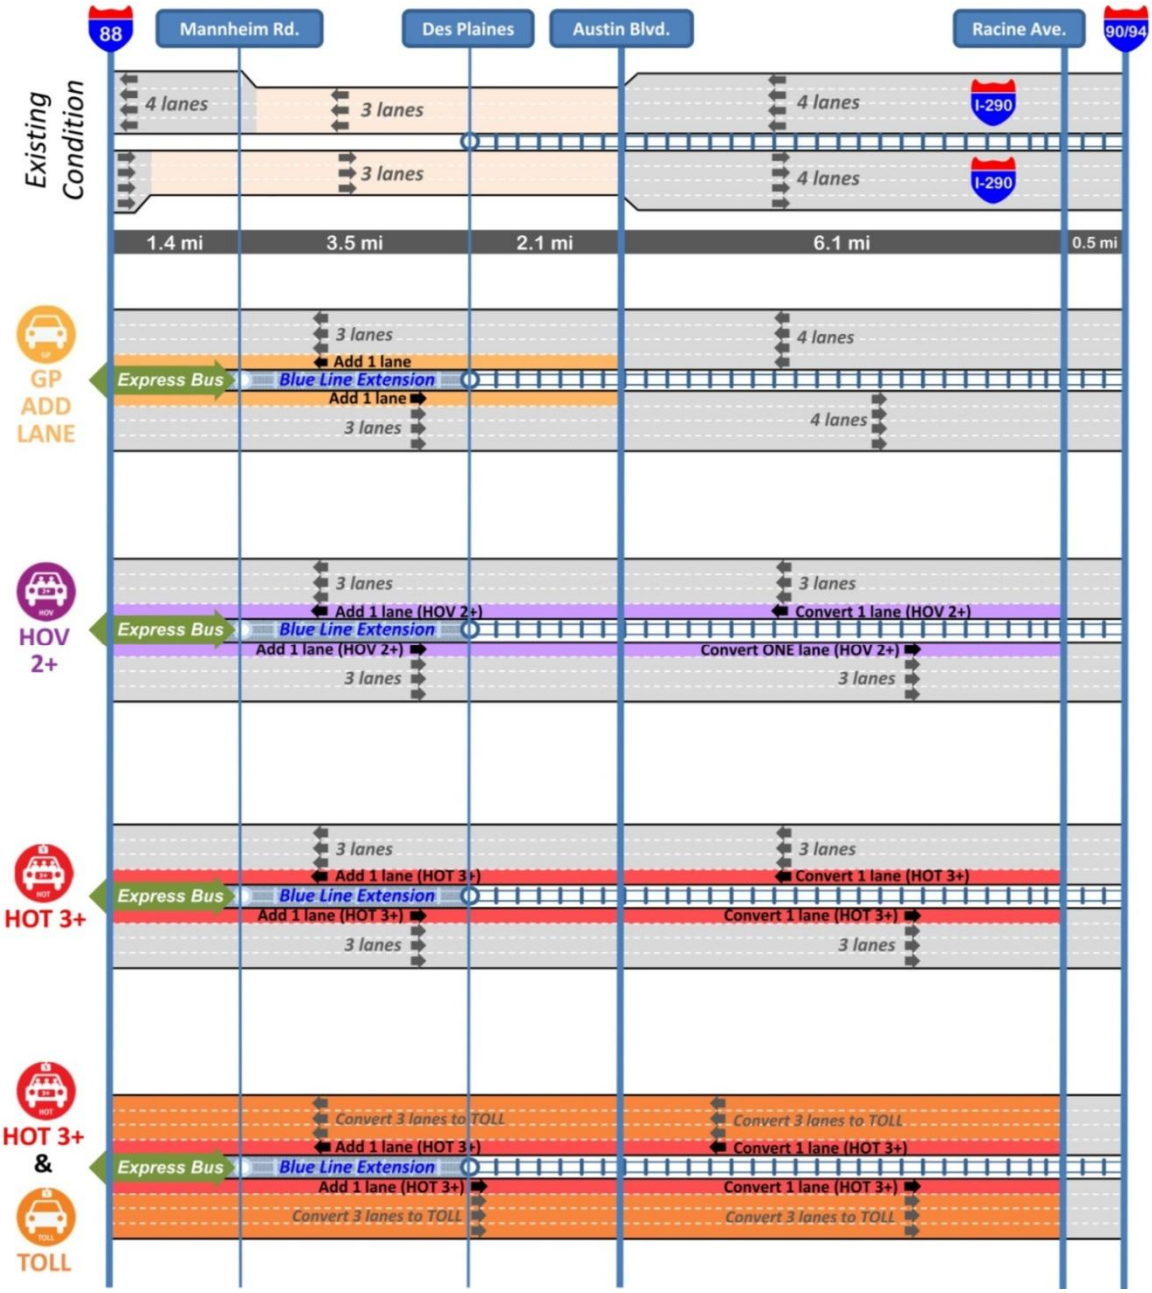


Source: WSP Parsons Brinckerhoff, 2016.

When ratio scoring is used (Figure 2-10 Ratio Scoring), the same alternatives score in the top four as with ordinal scoring, but with a more pronounced point gap separating the top three alternatives as GP & EXP & HCT, followed by HOT 3+ & TOLL & EXP & HCT, and HOV 2+ & EXP & HCT.

Figure 2-11 graphically illustrates a comparison of how the two methods are scored.

Figure 2-11. Comparison of Rank (Ordinal) and Ratio Scoring



Based on the results of the Round 2 evaluation, the top four alternatives were advanced for further evaluation in Round 3. A logical cutoff exists between the fourth and fifth ranked alternative, where the largest scoring gap between two successively ranked alternatives existed in ordinal scoring. The ratio method suggests three top alternatives with a scoring gap between the third and fourth ranked alternative. This confirmed the soundness of the process and the identification of four top-performing alternatives. These four alternatives selected for further evaluation in Round 3 cover a broad range of transit improvements and expressway management strategies. Figure 2-12 depicts the four alternatives.

General Observations

Adding a Lane to I-290

- The top four scoring alternatives include an additional lane on I-290 between Mannheim Road and Austin Boulevard, and an extension of the CTA Blue Line or a new BRT facility to Mannheim Road ("HCT") with supporting express and feeder bus services. Benefits of the top four alternatives include:
  - Adding a lane generally results in improved travel times (decrease in Vehicle Hours Traveled [VHT]) on I-290 as well as the arterial system.
  - Adding a lane on I-290 generally results in an increase in expressway travel (Vehicle Miles Traveled [VMT]) and a decrease in arterial travel (VMT).
  - Adding a general purpose lane attracts the most traffic onto I-290, while adding a managed lane with higher vehicle occupancy rates or pricing allows more people to travel through the corridor ("daily person throughput").

Figure 2-12. Four Combination Mode Alternatives to be Evaluated in Round 3

- Travel time savings provided by a tolled managed lane makes the Project Corridor relatively more attractive for longer distance trips and, consequently, longer distance trips shift onto I-290 and VMT is increased. However, there is a corresponding decrease in VHT due to the additional capacity provided.
- Tolling, even with adding a lane to I-290, generally results in relatively lower performance on the arterial system. Tolling makes I-290 slightly less attractive for shorter trips that would otherwise divert from the arterial system to I-290.
- Managed lanes result in net improvement in travel times in the remaining general purpose lanes. Existing (and future) carpoolers are drawn to the managed lane and away from the remaining general purpose lanes.

Not Adding a Lane to I-290

- The alternatives that did not include an additional lane on I-290, even in combination with an HCT and supporting bus services, performed relatively poorly.
  - The lack of an additional lane, coupled with congestion pricing or existing lane conversions that restrict flow on I-290, causes a significant shift of travel to an already congested arterial system.
  - Value (congestion) pricing shifts longer distance trips onto I-290 (increased VMT), but congestion pricing, without adding lanes to I-290, also has a net negative effect upon regional and arterial VHT due to the added capacity constraints imposed on the overall system.

Transit Service Expansion

- The alternatives that included HCT and supporting bus services created the relatively highest number of new transit trips, but more than 50 percent of the total ridership consists of trips diverted from other existing transit services.
- The alternatives that included HCT and supporting bus services provide new high-capacity options for the reverse commute.
- The alternatives that included HCT and supporting bus services generally resulted in increased VMT compared to alternatives without these transit components. This is because the HCT improvements in the Study Area shift some medium and shorter distance trips from auto to transit. This frees up capacity for longer distance auto trips to shift onto I-290.
- The alternatives that include HCT and supporting bus services provided slightly better safety performance compared to alternatives that did not include HCT, due to the shift in trips to transit (and to I-290), which has a higher safety performance.

The results matrix for the Round 2 evaluation of the 12 combination mode alternatives is included in Appendix C.

Overall and Combined Performance – Top Four Alternatives

As described above, the top four combination mode alternatives scored relatively higher than the other eight combination mode alternatives that were considered in Round 2. It should also be noted that these four combination mode alternatives all address the Purpose and Need, as overall regional and local travel performance is improved over the No Build Alternative, access to employment is greater than the No Build Alternative, overall safety is improved over the No Build Alternative, and modal opportunities are improved over the No Build Alternative. In addition, all four of these alternatives include reconstruction of I-290 between Cicero Avenue and Mannheim Road, addressing facility condition and design.

The following is a summary of the performance findings of each of the top four alternatives, based on the ordinal scoring method:

- The GP & EXP & HCT Alternative provides the best overall score of 28.4, driven by having the highest regional and local travel, and modal connections and opportunity improvements, as well as providing good safety performance. The added capacity attracts longer distance trips from the arterial network and onto the expressways for which they are intended. This shift from arterials also improves arterial performance in the Study Area, giving GP lanes the relatively highest overall performance for improving regional and local travel. Compared to the other alternatives, the GP lane combination alternatives showed a lower accessibility to jobs and safety performance. Accessibility to jobs for the GP lane combination alternatives is improved over the baseline condition, but not to the same extent as the managed lane alternatives due to the managed lanes providing a faster path than the GP lanes, therefore allowing users of the managed lanes to access more jobs located farther away in 60 minutes or less. With respect to overall safety, this GP lane combination mode alternative results in the best arterial safety due to the highest diversion of traffic from the arterials to the expressway, thus reducing the potential for crashes on the arterials.
- The HOV 2+ & EXP & HCT Alternative scored second best overall at 27.5. It provided the best safety performance and the second highest improvements to local and regional travel, as well as ranking as one of the top three for modal connections and opportunities. HOV lanes provided as much as a 40 percent reduction in daily hours of congestion in the managed lane, and more than 11 percent in the general purpose lanes. This is due in part to the already high percentage of HOV 2+ vehicles in this corridor that could use the HOV 2+ lane. The HOV 2+ combination alternatives indicated the highest overall safety performance improvements due to the increased auto and transit person throughput relative to the volume of traffic on the arterials and expressway.
- The HOT 3+ & EXP & HCT Alternative showed good overall performance, tied for third best in scoring at 26.8. The HOT 3+ alternatives show high person throughput, as the HOT 3+ lane allows better operations management control with toll pricing. Arterial performance was also good for this alternative as there is diversion of longer distance trips from the arterials to the expressway. There is also good performance

related to access to employment due to better operations management of the HOT 3+ lane that result in a relatively faster route (as compared to other combination alternatives) to jobs from the Study Area. Overall safety was also good due to the arterial diversion to the expressway and increased person throughput relative to the traffic volumes on the arterials and expressway.

- The HOT 3+ & TOLL & EXP & HCT Alternative showed good overall performance, tied for third best in scoring at 26.8. The HOT 3+ & TOLL Alternatives result in strong expressway travel performance due to the additional HOT 3+ lane in each direction and the lesser volumes on the expressway because of the tolls in all lanes. However, this is countered by the highest increase in arterial congestion for the combination alternatives with added expressway capacity as traffic is diverted from the expressway to the arterial due to tolling all expressway lanes. Similarly, expressway safety is relatively better (due to lower traffic volumes) and arterial safety is worse because more traffic on the arterials increases the risk of crashes. Job accessibility is also strong due to good expressway performance.

2.4.3 Round 3 DEIS Alternatives

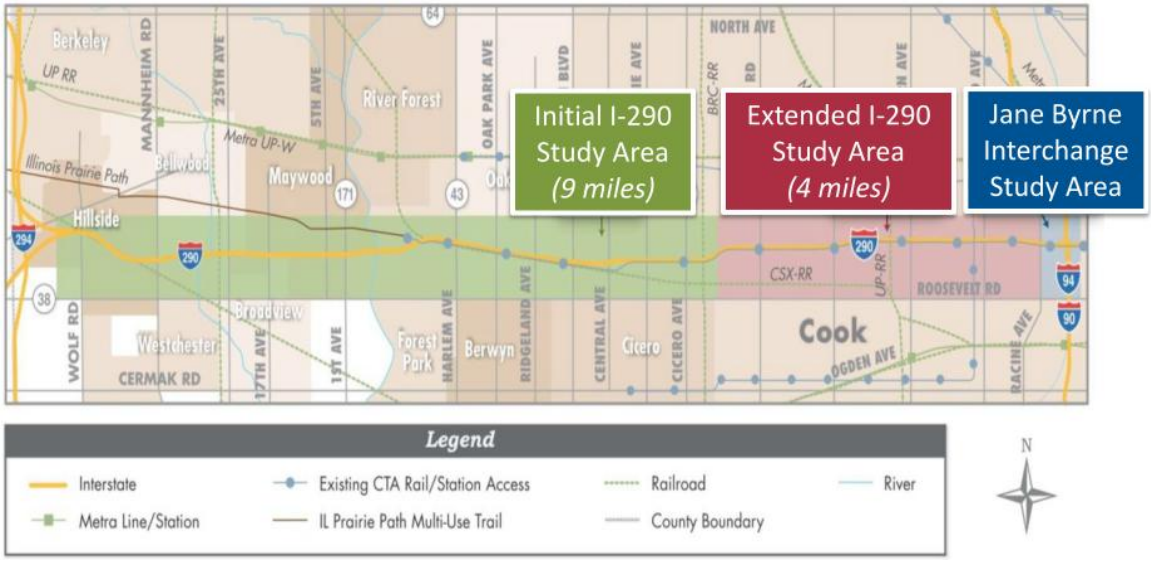
The results from the Round 2 evaluation established the set of mainline combination transit and expressway mode alternatives for detailed evaluation in Round 3. As described in the Round 2 evaluation, the overall scores of the top four combination mode alternatives were relatively higher than the remaining eight alternatives and, as such, the top four combination mode alternatives are carried into Round 3 along with the No Build Alternative. The build alternatives being advanced into Round 3 include:

- GP & EXP & HCT (also referred to as GP Add Lane Alternative)
- HOV 2+ & EXP & HCT (also referred to as HOV 2+ Alternative)
- HOT 3+ & EXP & HCT (also referred to as HOT 3+ Alternative)
- HOT 3+ & TOLL & EXP & HCT (also referred to as HOT 3+ & TOLL Alternative)

These alternatives are depicted in Figure 2-12.

2.5 Round 3 DEIS Alternatives

The result of the Round 2 combination mode evaluation led to the selection of four DEIS build alternatives and the No Build Alternative for further definition and evaluation in Round 3. Round 3 includes formal expansion of the Study Area east to Racine Avenue in Section 2.5.1, further definition of the build alternatives through an interchange type selection process, as described in Section 2.5.2, a summary of Round 3 travel performance in Section 2.5.3, and further refinement of the Round 3 alternatives in Section 2.5.4.



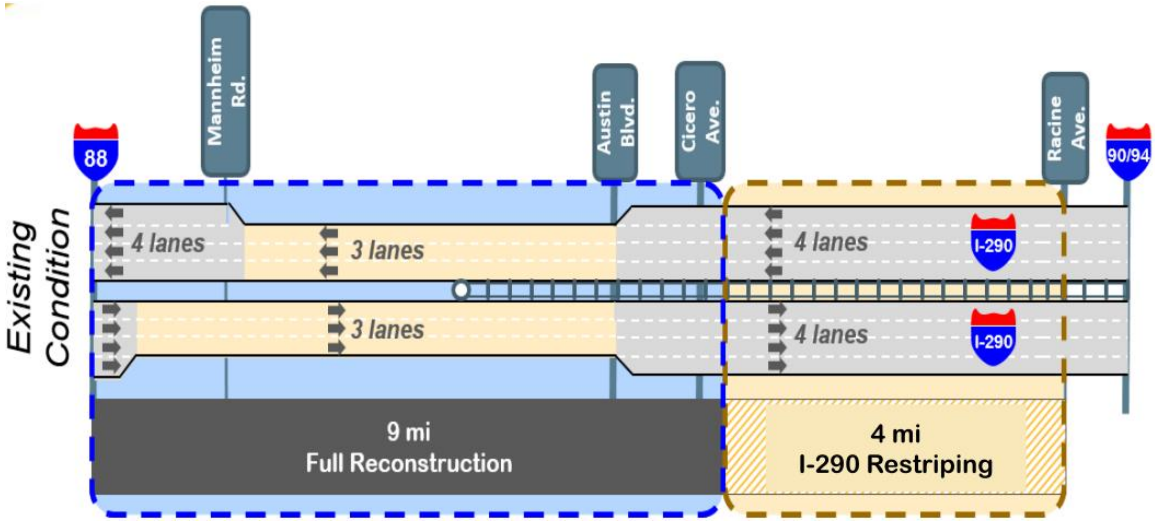
2.5.1 Study Area Extension

The initial Study Area spanned approximately 9 miles from the I-88/I-290 interchange to just east of Cicero Avenue to address the six-lane section bottleneck of I-290. As the

alternatives analysis progressed into the Round 2 evaluation, the managed lane and transit alternatives suggested by project stakeholders included operational improvements that extended east along I-290 to the Jane Byrne (former Circle) Interchange; therefore, the Study Area was formally extended to Racine Avenue for the Round 3 evaluation.

The I-290 revised Study Area is centered along I-290 in Cook County and extends approximately 13 miles from the I-88/I-290 interchange to Racine Avenue (Figure 2-13). This section of I-290 is a primary corridor serving travel between the western suburbs and the City of Chicago loop, as well as connecting southern Cook County to the high employment centers found in the I-88 Technology Corridor and the O'Hare commerce centers. The Study Area includes the seven villages of Hillside, Westchester, Bellwood, Broadview, Maywood, Forest Park, Oak Park, and also the City of Chicago.

Figure 2-13. I-290 Phase I Study Area



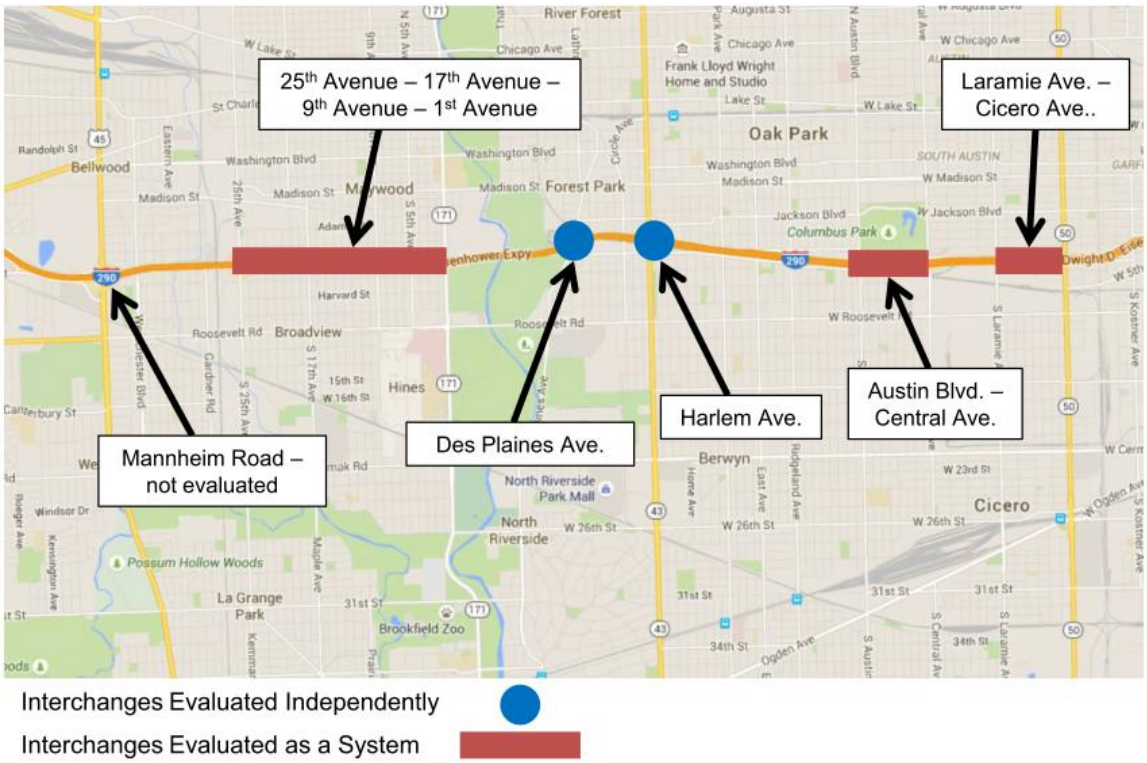
Source: WSP Parsons Brinckerhoff, 2016.

Racine Avenue was chosen as the revised eastern limit of the Study Area because this is also the western limit of the Jane Byrne Interchange Project. The Jane Byrne Interchange Project is addressing safety, facility condition, and congestion issues associated with this system interchange between I-290, I-90, and I-94. Construction of that project began in 2013.

Based on the needs analysis from the I-290 Study, no new expressway capacity is identified for the eight-lane section. As such, full reconstruction of this eight-lane section of the Study Area is not recommended. Any proposed operational changes in this section of the Study Area would be accommodated primarily via revised signing, restriping, and intelligent transportation system (ITS) improvements. No changes to the existing expressway interchanges and ramps are proposed, and the condition of the overhead bridges in the eight-lane restriping section is being addressed as part of separate studies being conducted by IDOT.

Figure 2-14 illustrates the overall 13-mile long Study Area, which is defined by two sections: a full reconstruction section (9 miles) and a restriping section (4 miles). The reconstruction section would require full reconstruction of the expressway and overhead bridges to accommodate the alternatives, which include additional lanes and alignment and profile changes. The restriping section does not require reconstruction to accommodate the alternatives and would consist primarily of new signing and pavement restriping.

Figure 2-14. I-290 Study Area Sections



Source: WSP Parsons Brinckerhoff, 2016.

2.5.2 Interchange Type Selection and Refinement Summary

This section describes the recommended interchange concepts to be further refined and evaluated in Round 3. The Combined Design Report fully describes the interchange alternatives considered and the process by which the recommended interchange types were identified. Design concepts at the 11 interchanges were evaluated along the Project Corridor as part of the Round 2 alternatives analysis. The Mannheim Road interchange was fully reconstructed in 2001 with the ramps and overhead bridge designed to accommodate future mainline reconstruction, including an added lane. Therefore, new interchange types for the Mannheim Road interchange were excluded from the interchange type studies.

Of the other 10 existing interchanges, some were evaluated independently due to their isolated nature, while others that are closely spaced or connected via frontage roads were evaluated as a "system," since the operations at one location could have an effect on an adjacent interchange. The primary evaluation factors were safety, geometric impact, traffic operations, and accommodations for potential nonmotorized and transit facilities. Figure 2-15 shows the evaluation type performed for each interchange.

Figure 2-15. Interchanges Evaluated

Source: WSP Parsons Brinckerhoff, 2016.

Stakeholder coordination was critical in the identification and development of the types and locations of interchanges in the corridor. In the Village of Maywood, an Advisory Working Group (AWG), consisting of local residents, business owners, municipal staff, and elected officials, met five times over 8 months with IDOT representatives to focus on the location and configuration of interchanges and access to the community at and in between 25th Avenue and 1st Avenue. During that time, IDOT staff also held 12 working meetings with municipal staff to work through the identification and evaluation of alternatives and to identify the preferred access alternative. Two broader town hall meetings were also held during this time to inform the community on the AWG progress and gather additional input.

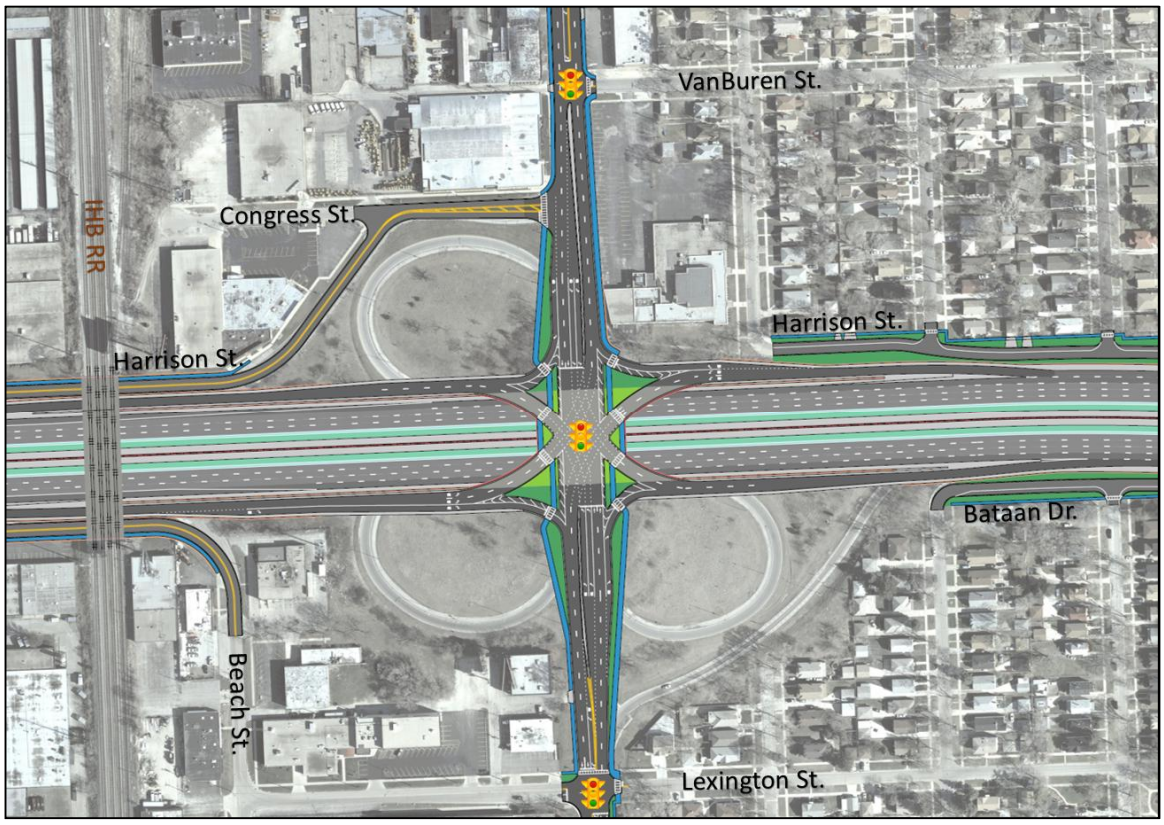
In the Village of Oak Park, a Working Group consisting of municipal staff and elected officials was assembled and met 21 times with IDOT representatives over a period of 17 months to discuss and refine project elements. The Working Group included focused reviews regarding the design and operations of the Harlem Avenue and Austin Boulevard interchanges. Eight special Village Board Study Sessions were held to inform the Village Board and community at large and to collect input on the project elements.

Evaluated Independently:

- DesPlaines and Harlem avenues: These interchanges are not directly connected to adjacent interchanges via a frontage road system; therefore, they were evaluated independently.

Evaluated as a System:

- 25th Avenue to 1st Avenue (including existing interchanges at 25th, 17th, 9th, and 1st avenues): There are nine existing ramp connections eastbound and eight existing ramp connections westbound in this 1.5-mile long section, with one-way parallel frontage roads connecting to the expressway via several slip ramps.
- Austin Boulevard and Central Avenue: These two interchanges are located 0.5 mile apart and do not meet current design guidelines for interchange spacing. Furthermore, the existing left-hand ramps at Austin Boulevard present safety and operational issues. Due to the close proximity of Austin Boulevard and Central Avenue, right-hand ramps at Austin Boulevard would conflict with the ramp design requirements for Central Avenue and require unique design considerations. For this reason, these two interchanges were evaluated together geometrically and operationally.
- Laramie Avenue and Cicero Avenue: Laramie Avenue and Cicero Avenue are closely spaced at 0.5 mile apart and connected by one-way frontage roads with slip ramps to I-290. These two half diamond interchanges effectively serve as one full interchange. For these reasons, Laramie Avenue and Cicero Avenue were evaluated as a system.



The proposed interchange concepts are the same for each build alternative; therefore, they are not factors in the Round 3 evaluation. The detailed evaluation of interchange alternatives and summary of the proposed interchange design and operations are included in the Combined Design Report for the project.

2.5.2.1 25th Avenue

At 25th Avenue, a Single-Point Urban Interchange (SPUI) was selected as the preferred concept for its high operational performance, its compact design, and compatibility with the land use plans of local villages (Figure 2-16). The compact SPUI would provide full access at 25th Avenue where currently only partial access exists. This design would replace the existing loop ramp configuration, providing additional space for stormwater detention ponds that would be used to accept stormwater overflow from the local communities and minimizing required right-of-way. The existing bridge carrying the IHB Railroad over I-290 would also be reconstructed to accommodate the added lanes, the acceleration/ deceleration lanes, and the two frontage roads.

A raised median along 25th Avenue would be required for the dual northbound and southbound left-turn lanes. To the south, the raised median would extend to just north of the signalized Lexington Street intersection, where northbound and southbound left-turn lanes would be added. To the north, the existing signal at Congress Street would be relocated north to Van Buren Street, a raised median would extend from the interchange to just south of the Van Buren Street intersection, and a southbound left-turn lane would be provided. Due to the raised median extending north to Van Buren Street, access to Congress Street would be reconfigured as right-in, right-out access only.

Figure 2-16. 25th Avenue Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

Nonmotorized improvements at 25th Avenue would include 10-foot-wide, Americans with Disabilities Act (ADA) accessible sidewalks and crossings along the east and west side of 25th Avenue over I-290. All proposed signals would include pedestrian crossing countdown timers.

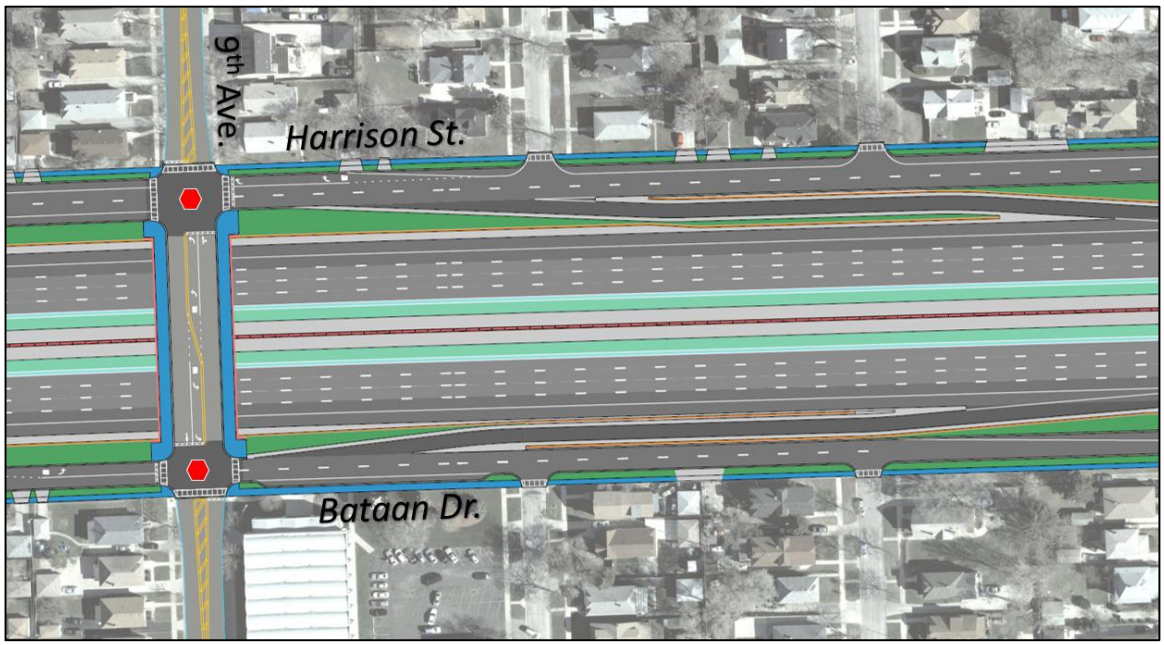
Only 0.54 acre of right-of-way would be required. 0.061 acre would be required in the northeast quadrant to accommodate the westbound-to-northbound ramp terminal and for widening 25th Avenue to accommodate dual southbound turn lanes. The existing parcel in the northeast quadrant is under consideration by the Village of Bellwood for commercial redevelopment, and the compact SPUI design would minimize right-of-way needed from this parcel. To the south, 0.46 acre of right-of-way would be needed along Indian Joe Drive due to a slight relocation of the frontage road to accommodate the improved I-290 cross section and new eastbound I-290 off-ramp to 25th Avenue. At the Lexington Street intersection, 0.0007 acre would be required to accommodate intersection improvements at Lexington Street.

2.5.2.2 17th Avenue

The proposed interchange concept at 17th Avenue would continue to provide full directional expressway access via improved slip ramp connections to/from Harrison Street and to/from Bataan Drive (Figure 2-17). 17th Avenue improvements would include a northbound right-turn lane at Bataan Drive, 12-foot-wide sidewalks and pedestrian plaza areas with ADA-accessible ramps, and modernized signals. This concept does not require any additional right-of-way.

Figure 2-17. 17th Avenue Proposed Interchange Concept

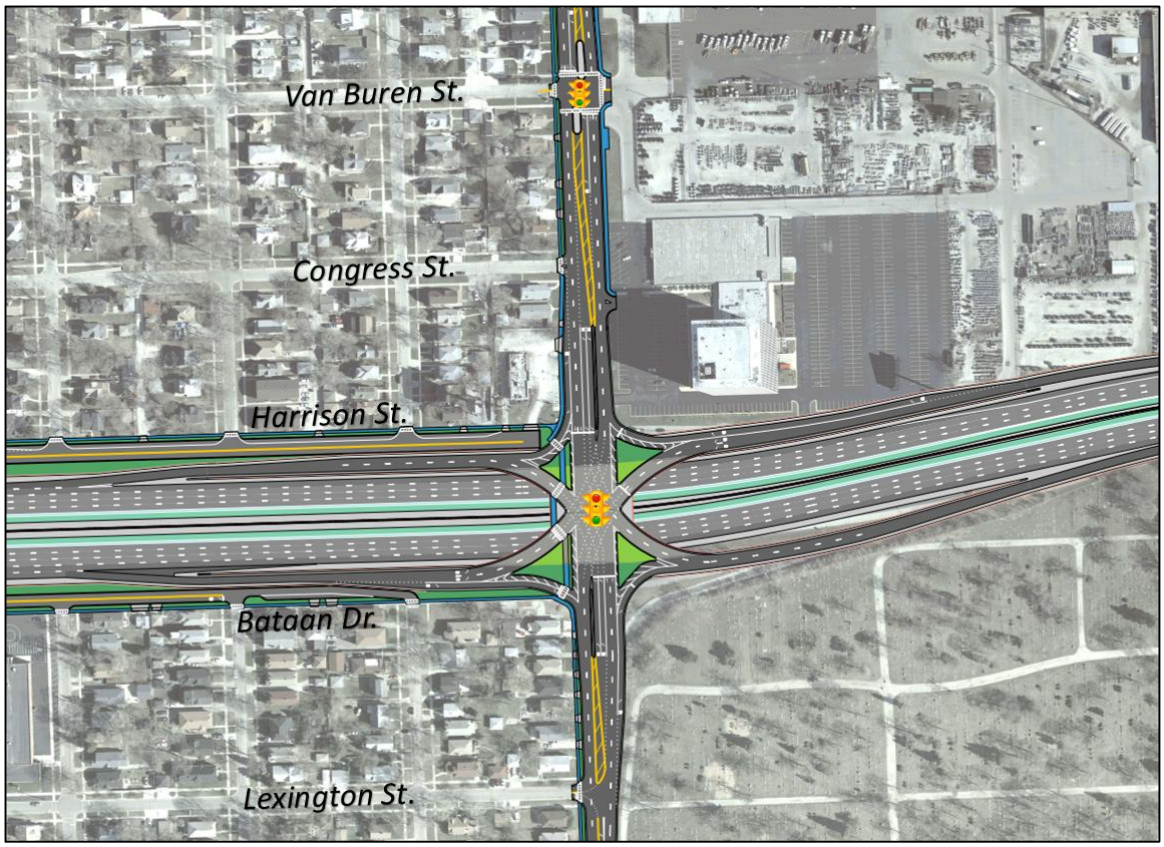
Source: WSP Parsons Brinckerhoff, 2016.



2.5.2.3 9th Avenue

The proposed interchange concept at 9th Avenue would continue to provide expressway access to and from the east via improved slip ramp connections to Harrison Street and from Bataan Drive (Figure 2-18). 9th Avenue improvements would include 12-foot-wide sidewalks and pedestrian plaza areas with ADA-accessible ramps and modernized signals. This concept would not require any additional right-of-way.

2.5.2.4 1st Avenue (IL 171)



At 1st Avenue, a SPUI was selected as the preferred concept for its efficient operation that would significantly reduce congestion and delay at this location (Figure 2-19). This very congested interchange currently operates at a failing level of service (LOS) F and experiences very long queues and extended delays on 1st Avenue. To improve performance at this interchange, the Harrison Street and Bataan Drive frontage roads would no longer connect with 1st Avenue. Dual left-turn lanes would be provided at all approaches, and signal phasing would be reduced from four to three phases. Compared to the 2040 No Build condition, the proposed SPUI would reduce delay by 74 percent and vehicle stacking by 77 percent.

Figure 2-18. 9th Avenue Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

Figure 2-19. 1st Avenue (IL 171) Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

Painted medians would be provided along 1st Avenue, except along the dual northbound and southbound left-turn lane storage areas, which would be protected from opposing traffic by a raised median. To the north, northbound and southbound left-turn lanes would be provided at Van Buren Street; a short section of raised median is proposed along 1st Avenue at the south leg of the Van Buren Street intersection to accommodate a pedestrian refuge island.

Nonmotorized improvements at 1st Avenue would include a signalized bike and pedestrian crossing of the Illinois Prairie Path at 1st Avenue and a 10-foot-wide ADA-accessible sidewalk along the west side of 1st Avenue and crossing over I-290. All proposed signals would include pedestrian crossing countdown timers. A bus pad and shelter area would be accommodated on the east side of 1st Avenue at Van Buren Street to provide improved transit amenities for Pace Bus Route #320, which serves the Maywood Workforce Center located in the Eisenhower Tower Building.

The compact design footprint of the 1st Avenue interchange would minimize the amount of right-of-way required, with 1.94 total acres required at this location. 1.9 acres would be required in the northeast quadrant between the expressway and Maybrook Drive for widening of 1st Avenue to accommodate dual southbound turn lanes, and northbound and southbound left-turn lanes at Van Buren Street; 0.039 acre of right-of-way would be required in the northwest corner of the interchange to accommodate improved geometry.

2.5.2.5 DesPlaines Avenue

At DesPlaines Avenue, the proposed interchange concept would maintain the existing ramp access to and from the west, and the ramps would be improved to meet current design standards (Figure 2-20). The proposed concept includes on-street bike lanes, 10-foot wide ADA-accessible sidewalks across both sides of the DesPlaines Avenue bridge, a shared use path bridge crossing of DesPlaines Avenue, and a shared use path connection to the east side of DesPlaines Avenue. All new signals would include pedestrian crossing countdown timers. Intersection improvements requested by the Village of Forest Park are also incorporated at the eastbound off-ramp connection with Harrison Street, including improved truck turning radii and improved turn lane channelization at each approach. CTA is planning to fully redevelop and modernize the Forest Park Blue Line Terminal & Yard and Shop facilities. CTA's proposed improvements include extending the CTA terminal over DesPlaines Avenue to provide direct terminal access from both sides of DesPlaines Avenue. The redevelopment plans also include converting Van Buren Street to two-way operations, as well as removing the parking lot on the south side of the terminal.

The proposed DesPlaines Avenue interchange concept is compatible with the current CTA Terminal site plan, as well as the future CTA terminal site concept as proposed at the time of this FEIS. The compatible design can accommodate the terminal site redevelopment without requiring bridge or ramp reconstruction.

Figure 2-20. DesPlaines Avenue Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

A total of 0.088 acre of right-of-way would be required, primarily north of I-290 along the east and west sides of DesPlaines Avenue, to accommodate improved 10-foot-wide sidewalks and 6-foot-wide bike lanes along DesPlaines Avenue.

2.5.2.6 Harlem Avenue (IL 43)

The proposed Harlem Avenue interchange concept is a modified SPUI design (Figure 2-21). Similar to a standard SPUI, the proposed interchange would operate with a single signal location; however, the ramp connections would be accommodated at Harlem Avenue in a compact configuration, comparable to a standard intersection. Expressway ramps would enter and exit I-290 from the right, then cross over the expressway to connect to Harlem Avenue at a compact four-leg intersection. This concept centers the intersection location over the expressway, maximizing the horizontal separation of the intersection from the adjacent signalized intersections at Jackson Boulevard and Harrison Street. No additional right-of-way would be required.

The compact design of the modified SPUI provides operational improvements that would include improved truck turning radii, improved lane channelization, dual left-turn lanes on the ramps, and increased queue storage on the off-ramps. The dual left-turn lanes and increased ramp traffic storage would minimize the risk of ramp traffic backing up onto the expressway through lanes and allow more signal green time to be allocated to the north-south traffic flow and pedestrian crossing movements along Harlem Avenue. Ramp turn signal phases would also be separated to reduce potential turning conflicts with improved

Figure 2-21. Harlem Avenue (IL 43) Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

safety. New signals at the Jackson Boulevard and Harrison/Garfield Street intersections would be coordinated with the interchange signal, which would also improve operations at both of these intersections.

Nonmotorized improvements would include wider ADA-accessible sidewalks across the bridge, pedestrian plaza areas in each corner of the intersection, and a wide transit plaza area near the CTA Harlem Avenue Blue Line station entrance. The wider sidewalk along the east side of Harlem Avenue could also accommodate a bus stop shelter for a new/relocated northbound bus stop located directly across from the CTA station. Crosswalks and pedestrian crossing countdown signals would be provided across all four intersection legs, and pedestrian refuge islands would be located between the ramps. North of the expressway, a ramp connection to the proposed grade-separated east-west shared use trail would be provided.

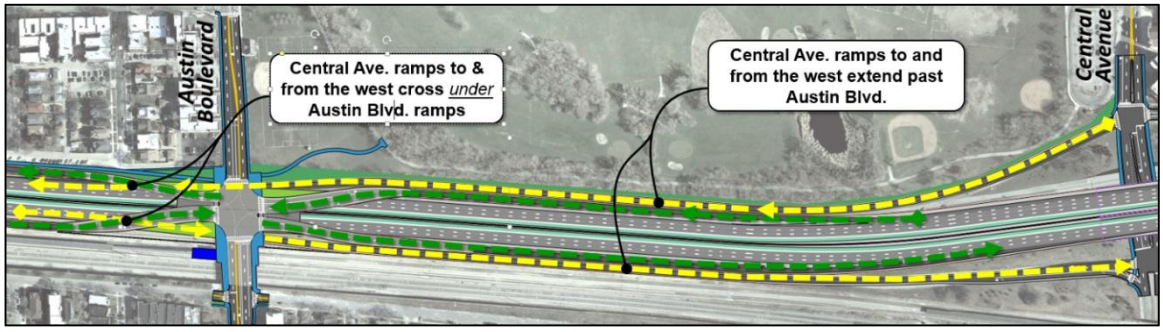
A total of 0.014 acre of right-of-way would be required by IDOT along the west side of Harlem Avenue, just north of I-290, to accommodate an improved 10-foot-wide sidewalk.

2.5.2.7 *Austin Boulevard*

The proposed Austin Boulevard interchange concept is a modified SPUI design (Figure 2-22). Similar to a standard SPUI, the proposed interchange would operate with a single signal; however, the ramp connections would be accommodated at Austin Boulevard in a compact configuration, comparable to a standard intersection. Expressway ramps would enter and exit I-290 from the right, then cross over the expressway to connect to Austin Boulevard at a compact four-leg intersection. This concept centers the intersection location over the expressway, maximizing the horizontal separation of the intersection from the adjacent signalized intersection at Harrison Street. No additional right-of-way would be required.

Figure 2-22. Austin Boulevard Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.



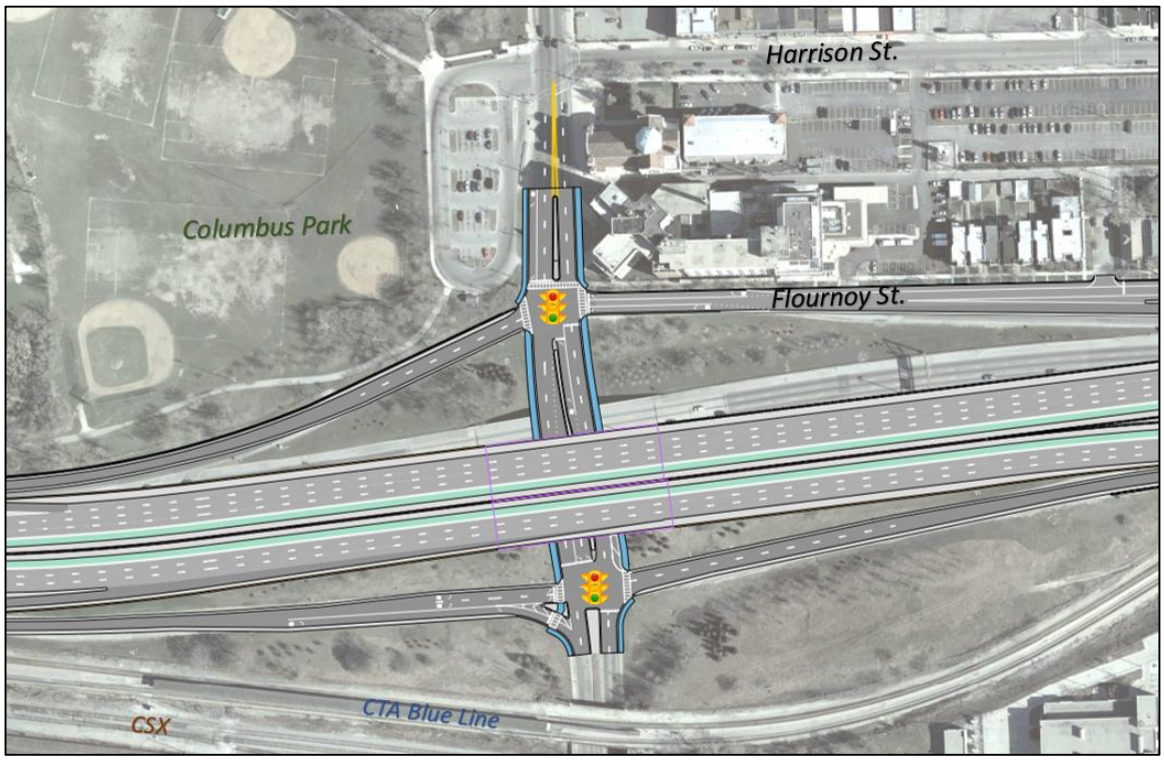
The compact design of the modified SPUI provides operational improvements that would include improved truck turning radii, improved lane channelization, dual southbound left-turn lanes, dual ramp left-turn lanes, and increased queue storage on the off-ramps. The dual left ramp turn lanes and increased ramp traffic storage would minimize the risk of ramp traffic backing up onto the expressway through lanes and would also allow more signal green time to be allocated to the north-south traffic flow and pedestrian crossing movements along Austin Boulevard. Ramp turn signal phases would also be separated to reduce potential turning conflicts with improved safety. A new signal at Harrison Street would be coordinated with the interchange signal, which would also improve operations at Harrison Street. Due to their close proximity to the

interchange ramp signal, Garfield Street and Railroad Avenue would be reconfigured for right-in, right-out only operations.

Nonmotorized improvements would include wider ADA-accessible sidewalks across the bridge, pedestrian plaza areas in each corner of the intersection, and a wide transit plaza area near the CTA Austin Boulevard Blue Line station entrance. The wider sidewalk along the east side of Austin Boulevard could also accommodate a bus stop shelter for a new/relocated northbound bus stop located directly across from the CTA station. Crosswalks and pedestrian crossing countdown signals would be provided across all four intersection legs, and pedestrian refuge islands would be located between the ramps. North of the expressway, the proposed east-west shared use path would connect at grade with Austin Boulevard. A connection of the shared use path to the Columbus Park path would also be accommodated.

Because of the close spacing of Austin Boulevard and Central Avenue, "braided" ramps would be provided to separate entering and exiting traffic between the two interchanges (Figure 2-23). The westbound on-ramp from Central Avenue and eastbound off-ramp to Central Avenue would be extended to the west and would cross under Austin Boulevard and the Austin Boulevard ramps. In this configuration, the off-ramps would enter the expressway prior to an on-ramp, which would improve mainline traffic weaving operations.

Figure 2-23. Austin Boulevard and Central Avenue Braided Ramp Configuration



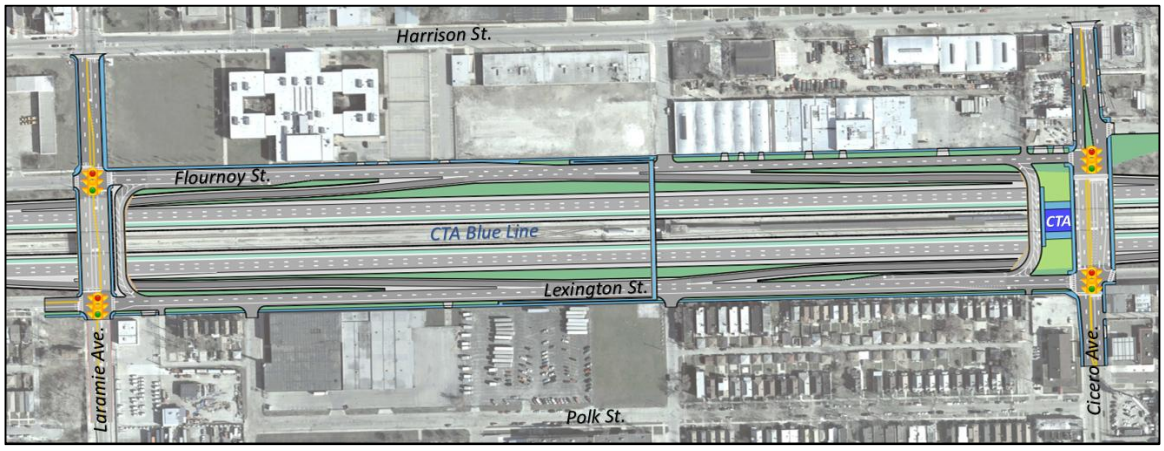
Source: WSP Parsons Brinckerhoff, 2016.

2.5.2.8 Central Avenue

At Central Avenue, the proposed interchange concept would maintain the diamond interchange configuration with some operational and geometric improvements to address current design standards, including dual left-turn lanes on the westbound off-ramp (Figure 2-24). 10-foot-wide, ADA-accessible sidewalks would also be included along both sides of Central Avenue between the ramp intersections. Ramp intersections would have modern signals that include pedestrian countdown timers. No new right-of-way would be required.

Figure 2-24. Central Avenue Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.



2.5.2.9 Laramie Avenue and Cicero Avenue (IL 50)

Laramie Avenue and Cicero Avenue are very closely spaced and overall operate as a single, full-access interchange (Figure 2-25). The proposed interchange type at Laramie Avenue and Cicero Avenue is identified as a reverse diamond with frontage road U-turns. The reverse diamond with U-turn concept maintains the existing ramp access locations, but it reverses their connections to provide an off-ramp followed by an on-ramp in each direction. This relocates the traffic weave between ramps from the higher speed, higher volume expressway onto the lower speed, lower volume frontage roads. No additional right-of-way would be required at Laramie Avenue or Cicero Avenue.

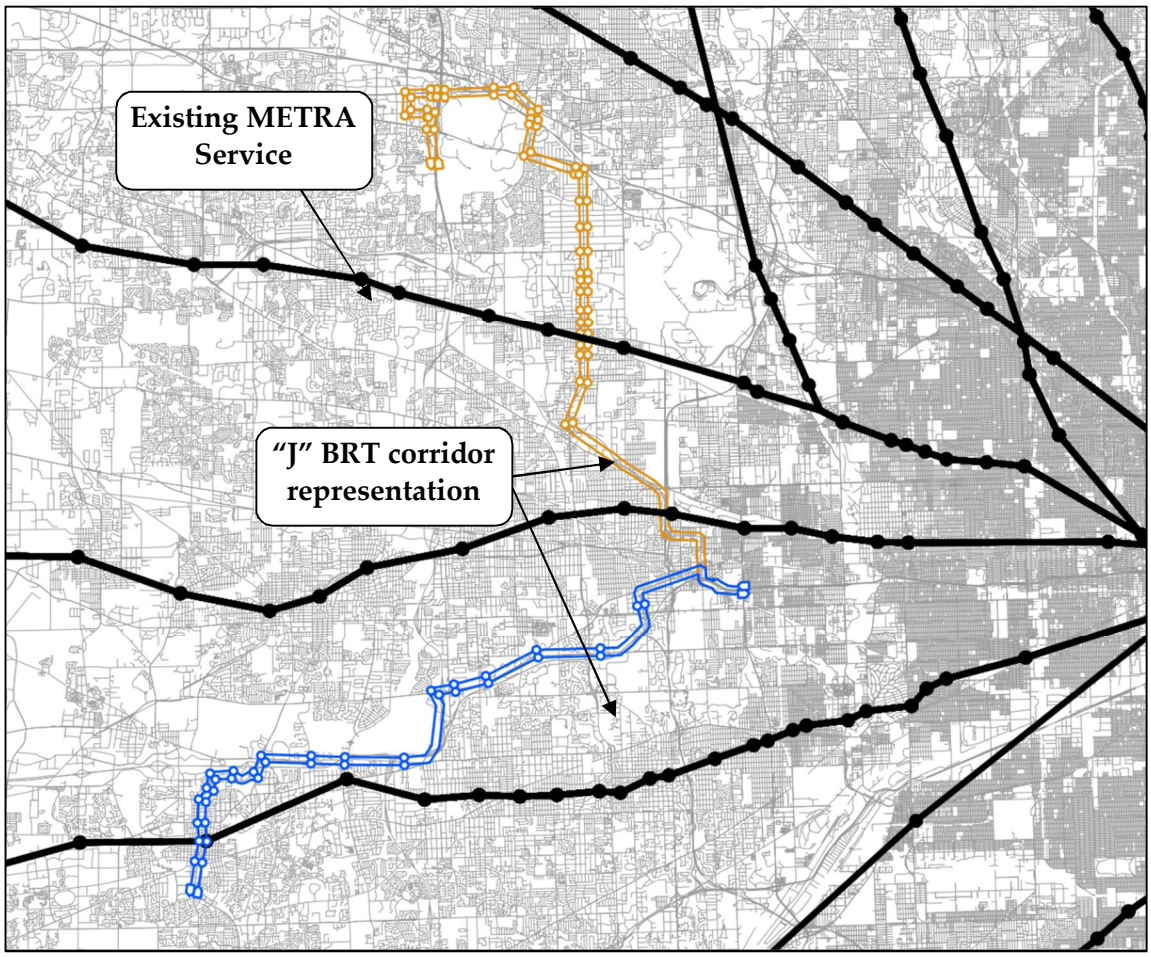
The U-turn design, sometimes referred to as a "Texas U-Turn" or "Texas Turnaround," allows for vehicles traveling on a one-way frontage road to U-turn onto the opposite frontage road by crossing under or over the freeway.

In this application, a U-turn west of Cicero Avenue would permit traffic heading east on Lexington Street to bypass the two signals at Cicero Avenue to head west on Flournoy Street if their ultimate destination is either westbound I-290 or Laramie Avenue. The U-turn at Cicero Avenue would also include a bus pullout at the CTA Blue Line Cicero Avenue Station to accommodate bus to rail transit transfers.

Figure 2-25. Laramie Avenue and Cicero Avenue (IL 50)
Proposed Interchange Concept

Source: WSP Parsons Brinckerhoff, 2016.

The U-turn east of Laramie Avenue would accommodate the westbound traffic in a similar way. Westbound traffic on Flournoy Street destined for Cicero Avenue or eastbound I-290 could use the U-turn to bypass the two intersections on Laramie Avenue to head eastbound on Lexington Street to access Cicero Avenue or eastbound I-290.



Nonmotorized improvements would include a new pedestrian bridge near Lavergne Avenue that would extend over Flournoy Street and Lexington Street and wider, ADA-accessible 10-foot wide sidewalks across the Laramie Avenue and Cicero Avenue bridges. Bus lanes that service bus stops in front of and across from the CTA Blue Line Station would be provided on the Cicero Avenue Bridge in the northbound and southbound directions. A new signalized pedestrian crossing of Cicero Avenue would be provided just south of the Flournoy Street intersection to improve bus transfers between the CTA station and the northbound bus stop. New signals would be provided at Cicero Avenue and Flournoy Street, and at Cicero Avenue and Lexington Street. All new signals would include pedestrian crossing countdown timers.

2.5.3 Round 3 Travel Performance

The Round 3 alternatives were tested using the travel demand forecasting model. The Round 3 travel performance results reflect use of the 2040 Build market-based population and employment forecasts, the revised Study Area definition described in Section 3.1, and a revised definition of the regional measures from the 21-county modeling area to the six-county northeast Illinois region (Cook, DuPage, Kane, Lake, McHenry, and Will counties).

The transit network was similar to that assumed in Round 2 with the HCT extension to Mannheim Road and bus network assumed, with the addition of two new bus routes representing the two branches of the proposed "J" BRT corridor feeding the Mannheim Road Station (as shown in Figure 2-26), and EXP from DuPage County using the managed lane and serving the University of Illinois Chicago Campus and the Illinois Medical District.

Figure 2-26. Round 3 Transit Network

Source: WSP Parsons Brinckerhoff, 2016.

For the managed lane alternatives (HOV and HOT), the west terminus was I-88 and the east terminus was Ashland Avenue. Intermediate access/egress for the managed lane was assumed at 1st Avenue, Austin Boulevard, and California Avenue. Congestion pricing was assumed for the HOT 3+ lane. Toll rates of $0.20 per mile during the morning and afternoon peak periods (7:00 to 9:00 a.m. and 4:00 to 6:00 p.m.), $0.16 per mile during the peak shoulders (6:00 a.m. to 7:00 a.m., 9:00 to 10:00 a.m., 2:00 p.m. to 4:00 p.m., and 6:00 p.m. to 8:00 p.m.), and $0.12 per mile during the off-peak periods (10:00 a.m. to 2:00 p.m., and 8:00 p.m. to 6:00 a.m.) were assumed. A $0.12 per mile toll was assumed for the tolling of the existing three lanes in each direction on I-290 for the HOT 3+ & TOLL Alternative.

The travel performance for the four Round 3 build alternatives was compared to the No Build Alternative and is presented in Table 2-9. Figures in green denote an improvement, and figures in red a worsening of performance compared to the No Build Alternative.

Table 2-9. Round 3 Travel Performance Comparison (Showing Change from 2040 No Build)

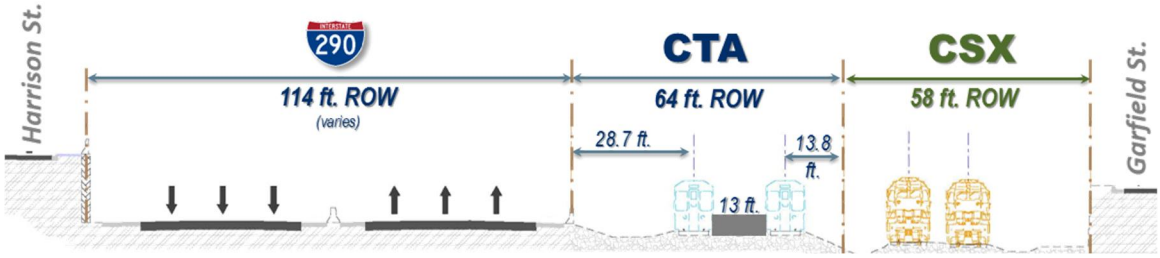
Travel Measure	No Build Alternative	GP & EXP & HCT Alternative	HOV 2+ & EXP & HCT Alternative	HOT 3+ & EXP & HCT Alternative	HOT 3+ & TOLL & EXP & HCT Alternative
Regional VMT (miles)	201,187,710	+151,380	+72,492	+52,211	+33,774
Regional VHT (hours)	8,067,709	-9,840	-9,773	-16,161	-17,300
I-290 Travel Time (Min) (GP/ML)	30.7 / NA	21.2 / NA	23.2 / 13.7	23.0 / 13.5	14.8 / 12.6
Study Area Arterial VMT (miles)	4,294,011	-24,560	+6,944	-8,853	+147,834
Study Area Arterial VHT (Hours)	255,282	-1,996	-967	-1,643	+6,778
Person Throughput	459,122	+25,247	+31,871	+28,604	+25,294
Job Accessibility	5,151,539	+105,053	+364,948	+397,660	+326,499
Overall Safety (crashes per million person miles per year)	0.287	-4.86%	-6.44%	-6.21%	-4.65%
East-West Transit Trips	76,950	+4,375	+2,150	+4,425	+8,425

Source: WSP Parsons Brinckerhoff, 2016.

The travel performance of the Round 3 build alternatives is summarized below.

- GP & EXP & HCT: This alternative had the greatest reduction in arterial VMT and VHT, but also had the greatest increase in regional VMT. This is because the added capacity of the GP lane in each direction between Mannheim Road and Austin Boulevard is not managed; therefore, this additional capacity is nearly fully used, resulting in the most diversion of longer distance trips from the arterials to the expressway. This alternative had the largest increase in regional VMT because more trips are attracted to the expressway system to utilize the additional I-290 capacity. The GP Add Lane also had the second lowest decrease in regional VHT and lowest person throughput. These two travel measures are good indicators of efficient use of the transportation system, because it is the most beneficial to minimize time spent traveling on the highway system and to maximize person throughput. Since the

added GP lane is not managed, it does not encourage carpool use or promote more efficient use of the additional capacity. In addition, the GP lane had the lowest job accessibility due to the lack of a faster managed lane, although the alternative does improve travel times on I-290 versus the No Build Alternative.



- HOV 2+ & EXP & HCT: This alternative had the highest person throughput, primarily due to the HOV lane, which encourages carpooling. It should be noted that even though this alternative had the lowest increase in east-west transit trips, this was more than offset by the increase in carpool use and more efficient management of the added capacity resulting in the highest person throughput. However, the HOV2+ Alternative had the lowest decrease in regional VHT, in part due to the second highest increase in regional and arterial VMT (as regionally, carpool vehicles are driving farther to get to the additional capacity provided by the HOV lane, and the greatest benefit for diverting from arterial to expressway trips is for carpool vehicles), and the lowest increase in east-west transit trips (due to the most competition for forming new carpools versus switching to transit). Job accessibility is the second highest due to the travel time advantages provided by the managed HOV lane. The HOV 2+ Alternative had the highest overall safety improvement.
- HOT 3+ & EXP & HCT: This alternative had the second lowest increase in regional and arterial VMT and the second highest reduction in regional and arterial VHT. This is due to the additional capacity provided by the HOT 3+ Alternative lane and the reliability and efficiency of its operation; this alternative encourages carpools with 3 or more persons and allows others to pay tolls for a guaranteed faster trip through the use of congestion pricing. As a result, the HOT 3+ Alternative attracts more arterial diversions than the HOV 2+ Alternative and has slightly faster travel times in both the managed lane and general purpose lanes than those of the HOV 2+ Alternative. The HOT 3+ Alternative has the second highest person throughput because it is encouraging 3+ carpools, has the second highest increase in east-west transit trips, and has faster, more reliable managed lane operation based on congestion pricing. It also has the highest job accessibility due to both the improved managed lane travel time and the improvement in arterial performance. Overall, the HOT 3+ Alternative is first or second best in improvement for all of the travel measures, so this alternative provides very balanced transportation benefits.
- HOT 3+ & TOLL & EXP & HCT: This alternative had the lowest increase in regional VMT, the highest reduction in regional VHT, and the fastest I-290 general purpose and managed lane travel times. This is due to the tolling of all of the lanes on I-290 that results in the least traffic on I-290 because of drivers avoiding tolls by diverting from the expressway to arterials. As a result, the HOT 3+ & TOLL Alternative has the highest increase in arterial VMT and VHT, and it has the lowest overall safety improvement. The HOT 3+ & TOLL Alternative has the second lowest person throughput due to lower expressway volumes that more than offset the highest increase in east-west transit trips.

2.5.4 Other Round 3 Refinements and Considerations

2.5.4.1 Expressway and Railroad Right-of-Way Evaluation

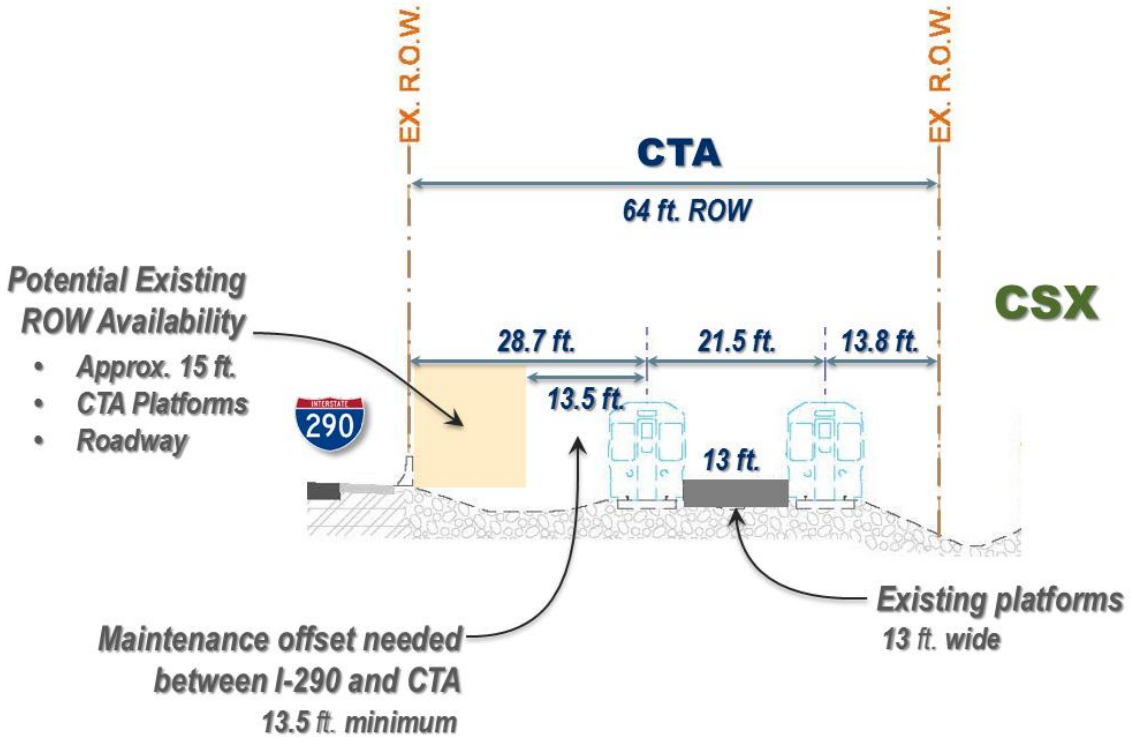
As part of the I-290 Study, IDOT evaluated the availability of CTA and freight railroad right-of-way from just east of Austin Boulevard to Circle Avenue to determine an optimal cross-section configuration that considers the needs of CSX Transportation freight rail, CTA rapid transit, and the I-290 Expressway. The typical section, which represents the most constrained section of this area, is located just east of Oak Park Avenue (Figure 2-27).

Figure 2-27. Existing Expressway and Parallel CSX and CTA Constrained Section

Source: WSP Parsons Brinckerhoff, 2016.

CSX Right-of-Way Availability and Typical Section:

Within this footprint evaluation Study Area, CSX operates in a generally 58-foot-wide strip of parallel right-of-way located south of I-290 and CTA. The southern edge of the CSX right-of-way is primarily defined by a retaining wall that extends along the majority of its trackage in this area.



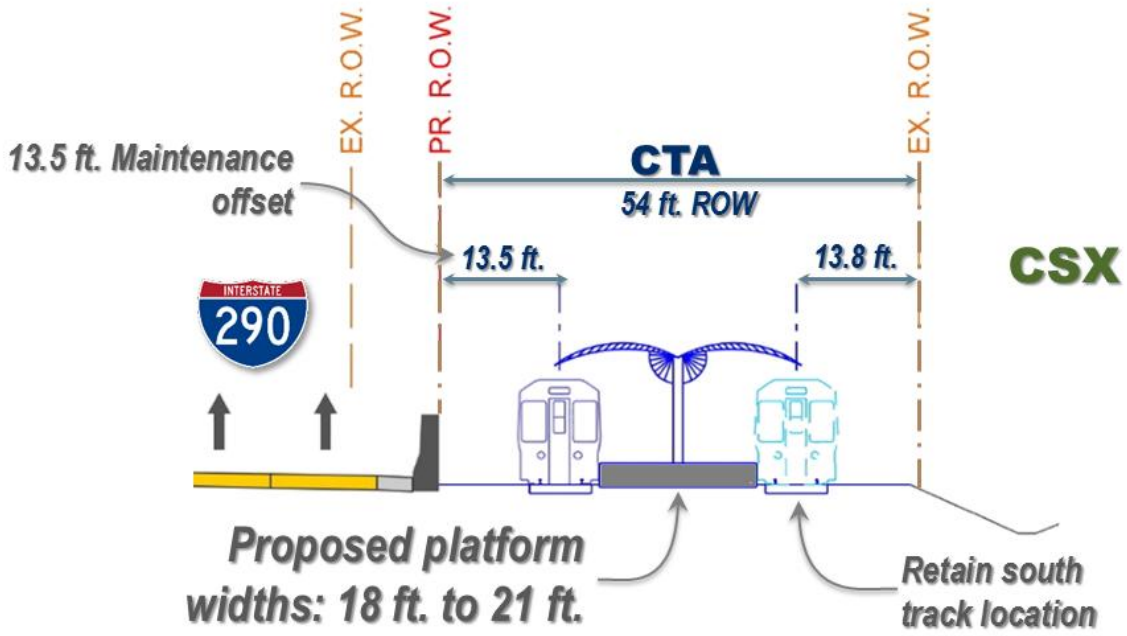
Currently, there are two mainline tracks in this area and a siding track where CSX services the Ferrara Candy Company located along the south edge of the Project Corridor, just east of Circle Avenue. CSX provides weekly rail deliveries to this client (Figure 2-28).

Regarding horizontal clearances, CSX indicated that this is an active freight corridor. As such, CSX stated a need to accommodate a minimum two-track envelope to maintain service and that there is no excess CSX right-of-way available.

CTA Right-of-Way Availability and Safety Evaluation:

The CTA Blue Line Vision Study concluded that as part of the Blue Line modernization needs, the Austin, Oak Park, and Harlem stations would remain in place and would continue to be accessed via dual head houses located at the adjacent cross streets with track-level platform access end-loaded as it is today. The Blue Line Vision Study also concluded that a third or express track is not needed and is not proposed as part of the modernization. Based on the results of the Blue Line Vision Study, CTA indicated that up to 15 feet of CTA right-of-way could be available for expressway improvements.

Figure 2-28. Existing CTA Right-of-Way Configuration



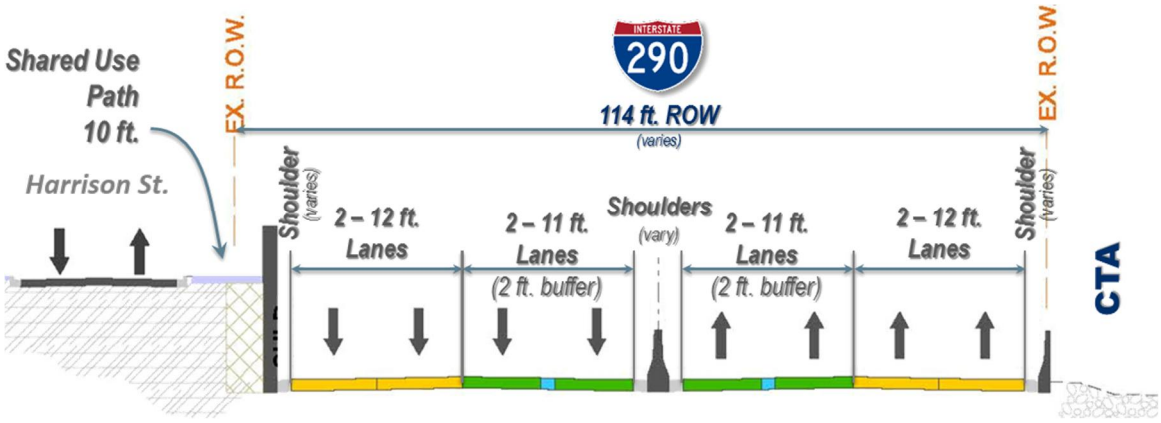
Source: WSP Parsons Brinckerhoff, 2016.

CTA stipulated that any use of CTA right-of-way would require platform widening to accommodate future ridership and up to a 10-car train; a 13.5-foot-wide maintenance offset between the proposed I-290 barrier and the centerline of the CTA rapid transit tracks; and a review of proposed platform widths per National Fire Protection Association (NFPA)-130.

Assuming an expressway improvement utilizing up to 10 feet of CTA right-of-way to accommodate wider shoulders and/or lanes, the resulting space available for platform widths were determined and evaluated. In this evaluation, the south track was assumed to remain on its current alignment, and the north track would be shifted to accommodate wider platforms. The platform widths that could be accommodated (assuming up to 10 feet of CTA right-of-way is used for I-290 improvements) are from approximately 18 to 21 feet wide. Figure 2-29 illustrates generally how the I-290 and CTA right-of-way is proposed to be allocated. Each station platform can accommodate a 10-car train; however, the length of the platform was not a factor in the determination of right-of-way evaluation.

IDOT evaluated the proposed platform widths to determine if the widths would meet the NFPA-130 fire code egress time requirements.

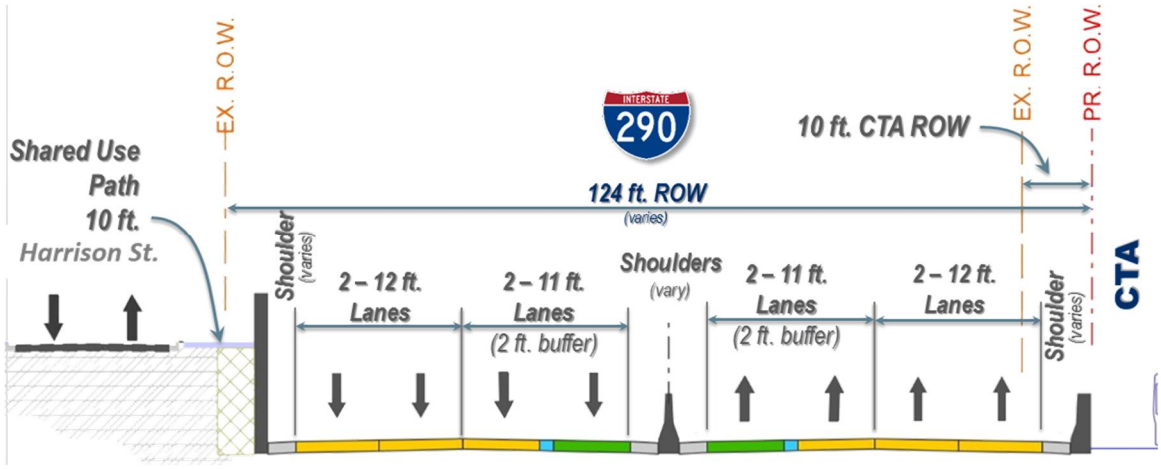
Figure 2-29. 10-Foot Right-of-Way and CTA Right-of-Way Configuration



Source: WSP Parsons Brinckerhoff, 2016.

The conceptual platform widths, as proposed for the Harlem, Austin, and Oak Park stations, were found to allow passengers to be evacuated to the street-level sidewalk areas outside the stationhouses within the NFPA-130 time requirements. The analysis indicated that emergency passenger evacuation is primarily affected by the configuration of stationhouse egress barriers (i.e., turnstiles, roto gates, accessible fare gates, emergency exit gates, and station exit doors/gates) than by the width of the end-loaded platforms. Simply increasing platform widths beyond the proposed dimensions (and thereby the clear widths of vertical circulation elements) is not a key factor in reducing total evacuation time per NFPA 130 - 2014. Further and more detailed fire code safety analysis would be required during final design to account for any proposed platform features/amenities and other obstructions.

I-290 Safety Evaluation



Two expressway geometric alternatives were evaluated as part of the right-of-way footprint evaluation; an alternative that required no right-of-way from CTA (Figure 2-30), and an alternative that assumed up to 10 feet of CTA right-of-way (Figure 2-31)were available to accommodate wider shoulders and/or lanes.

Figure 2-30. I-290 Expressway Improvement Configuration without 10-Foot CTA Right-of-Way

Source: WSP Parsons Brinckerhoff, 2016.

Figure 2-31. I-290 Expressway Improvement Configuration with 10-Foot CTA Right-of-Way

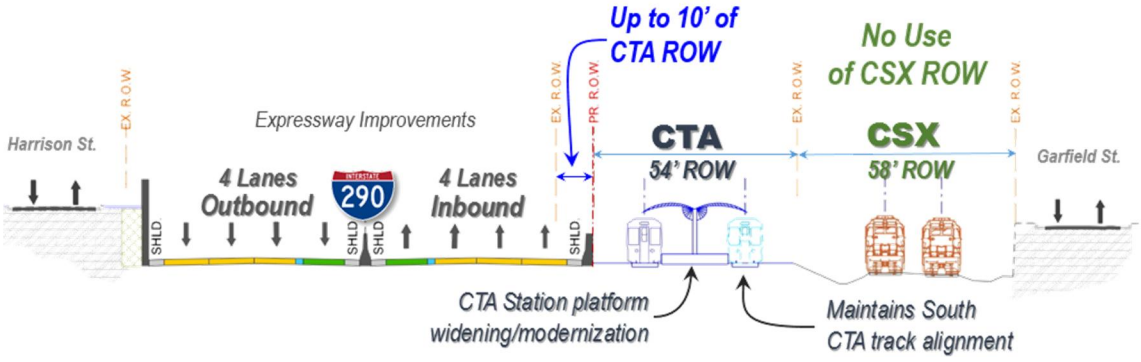
Source: WSP Parsons Brinckerhoff, 2016.

The expressway safety performance of both geometric alternatives was evaluated to determine the best overall lane and shoulder configurations. The Interchange Safety Analysis Tool-Enhanced (ISATe) predictive highway safety evaluation tool developed by TTI was used to test the mainline geometry. The summary of the analysis is presented in Figure 2-32.

Figure 2-32. I-290 Expressway and CTA ROW Safety Evaluation

ISATe Expressway Safety	Lanes (each direction)	Shoulders (minimum)	Injury Crash Reduction (Compared to NoBuild)	Overall Crash Reduction (Compared to NoBuild)
1. No ROW	2 @ 11ft 2 @ 12ft	2ft inner 2ft outer	**-3.9%**	**-11.8%**
2. 10ft. CTA ROW	2 @ 11ft 2 @ 12ft	4ft inner 4ft outer	**-9.6%**	**-15.1%**

Source: WSP Parsons Brinckerhoff, 2016.



Both expressway alternatives provide safety benefits for reducing injury crashes and overall crashes. Mainline capacity improvement is the primary factor increasing safety for the no CTA right-of-way alternative. Wider shoulders were also found to be key safety factors, in that wider outside shoulders provide a greater safety benefit than wider lanes. Overall, lane widths were not found to be a primary safety performance driver, and if additional space were available to accommodate all 12-foot-wide lanes, the incremental safety benefit would be an additional 0.3 percent decrease in the overall crash rate.

Utilizing up to 10 feet of CTA right-of-way to provide wider shoulders is predicted to provide an additional 3.3 percent decrease in overall crash rate and an additional 5.7 percent decrease in the injury crash rate (more than double the reduction) from the crash rates of the no CTA right-of-way alternative.

Conclusions:

Based on the geometric and safety analysis, up to 10 feet of CTA right-of-way would be utilized for the I-290 improvements, which would more than double the expressway safety performance while also accommodating between 5 and 7 feet of station platform widening, ADA requirements, CTA operational needs, and fire safety requirements (Figure 2-33).

Figure 2-33. I-290 Expressway and CTA Right-of-way Proposed Configuration

Source: WSP Parsons Brinckerhoff, 2016.

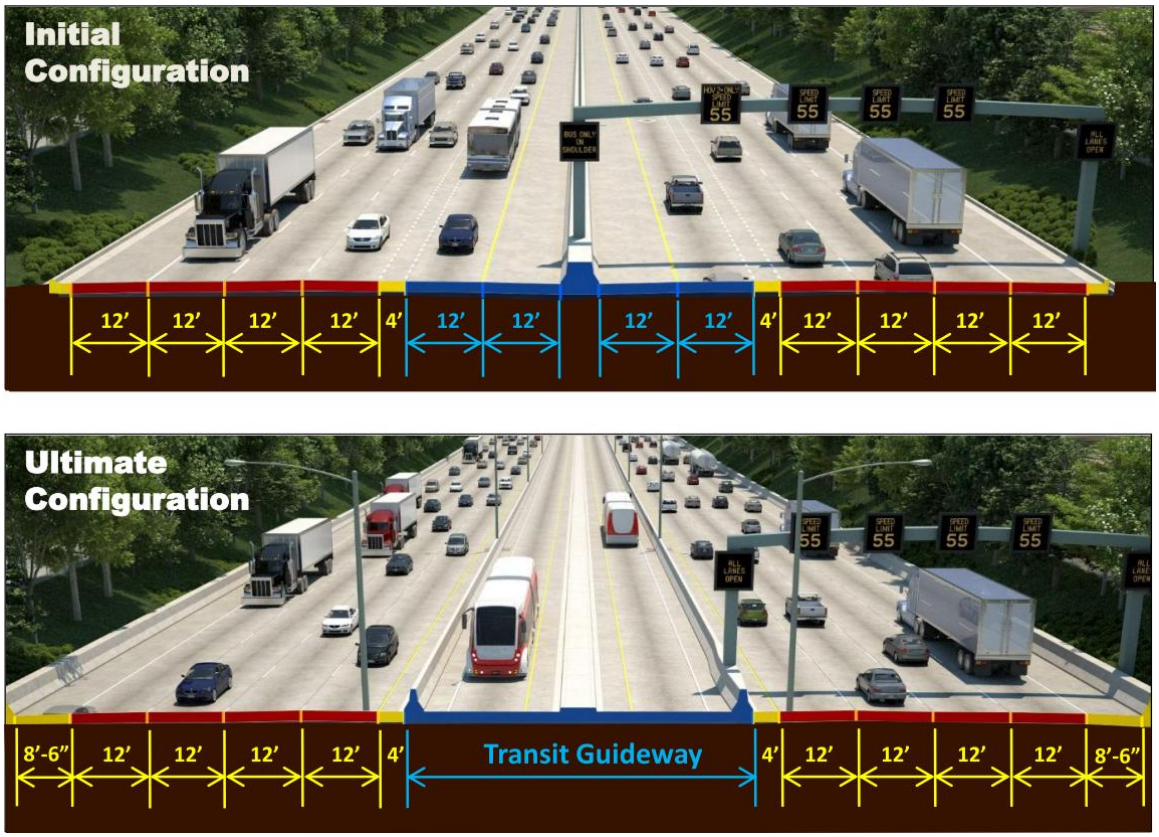
2.5.4.2 CSX Railroad Vertical Clearance Evaluation

Between Circle Avenue and Central Avenue, CSX freight railroad tracks run parallel to I-290 and the CTA Blue Line along the south wall of the existing "trench." The existing vertical clearances from the top of the track to the underside of the cross-road bridges between Circle Avenue and Central Avenue do not meet the 23-foot-high vertical clearance required for reconstruction by freight railroad design standards and as identified under IDOT reconstruction criteria in the Bureau of Design and Environment (BDE) Manual Section 39-4.06. Providing a vertical clearance of 23 feet by raising crossroad profiles would result in displacements and impacted properties along the crossroads. Overall, increasing the vertical clearance to 23 feet cannot be justified based on impacts.

Based on coordination with CSX representatives, CSX indicated that a 21-foot, 9-inch vertical clearance is acceptable for their operations. Scenarios were developed and evaluated considering railroad and crossroad profiles, vertical clearance provided, impacts to the existing retaining wall, drainage, and cost. A scenario was developed that provides 21-foot, 9-inch minimum vertical clearance from Austin Boulevard to Circle Avenue without raising crossroad bridge profiles through a combination of some lowering of CSX and utilizing a reduced depth, post-tensioned bridge deck for the crossroad spans over the railroad tracks. The average depth of lowering is 8 inches and is shallow enough that it is not anticipated to impact the existing retaining wall and require its reconstruction. The additional proposed I-290 trunk sewer capacity, combined with 3-acre feet of underground vault storage, should provide CSX with 100-year storm inundation protection, which they currently do not have.

2.5.4.3 CTA Vision Study Findings

In coordination and in parallel with the I-290 Study, CTA performed its own Blue Line Forest Park Branch Feasibility/Vision Study[3] to determine the immediate and long-term improvement needs along this line. Among its findings are the following:



- The Forest Park Branch should be brought to a state of good repair to address deficiencies in track, signals, and stations. The stations closed in the 1970s should be removed.
- CTA should continue to coordinate with IDOT on corridor improvements, including overhead bridges to improve stations and street access, project coordination to achieve long-term cost savings for both projects, and a transit alternative during I-290 construction.
- The Forest Park terminal, yard, and shop should be modernized to improve site circulation and to meet increased rail yard and shop needs, and should be configured to allow a future western extension.

[3] Blue Line Forest Park Branch Feasibility/Vision Study Website: http://www.transitchicago.com/blueweststudy/.

- A third express track (for which space was provided for in the original Project Corridor planning) is not needed; the existing station spacing currently allows the line to function as a west side express. As a result, 10 of the 21 feet of existing vacant CTA right-of-way space is available for I-290 improvements and is compatible with the identified future CTA Blue Line improvements.
- The extension of the Forest Park Branch to the west is not a short-term priority for CTA, but provisions should be made within the project to preserve future extension options to Mannheim Road.

The proposed expressway design is configured to accommodate a future HCT guideway along the median of I-290 from 1st Avenue to east of Manheim Road. All proposed bridge piers, frontage roads, ramps, and retaining walls would be constructed such that they could remain in place when the HCT is added. The space for inside lane and shoulder would be utilized for the transit guideway, and the remaining expressway pavement would remain in place, requiring a minor reconfiguration of the inside auxiliary lane in each direction for use as a through lane. Figure 2-34 illustrates the convertible section concept that would accommodate this CTA Vision Study finding.

Figure 2-34. Convertible Expressway Concept – Initial and Ultimate Configuration

Source: WSP Parsons Brinckerhoff, 2016.

2.5.4.4 Railroad Right-of-Way Allocation and Vertical Clearance Recommendation

Based on the findings for the right-of-way and profile evaluations and in consideration of CTA's Vision Study findings, a combination solution of obtaining 10 feet of right-of-way from CTA and improving clearances over the CSX Railroad to a minimum of 21 feet 9 inches via reduced crossroad bridge depths and minor track lowering is recommended. Utilizing 10 feet of CTA right-of-way would result in improved safety performance at a reasonable cost and level of implementation complexity. CSX access to Ferrara Candy Company would remain in place, although the minor track lowering and some track alignment reconfiguration would likely result in some temporary operational impacts during construction. Construction risks and impacts to the existing south retaining wall, which is still in good condition, would be minimized.

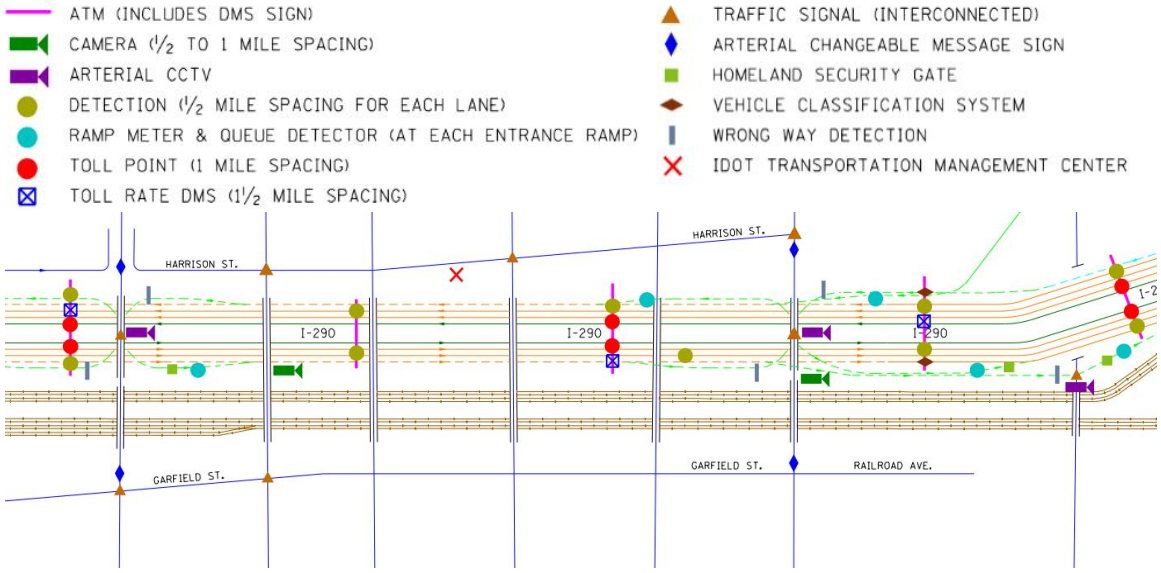
2.5.4.5 Intelligent Transportation System Components

To maximize the safe and efficient flow of traffic in the Project Corridor, ITS concepts would be used to provide integration of devices and operational strategies on I-290, as well as on the adjacent state arterial network. The expectation is that the ITS concepts would help with traffic management during construction and after completion of the I-290 improvements.

The initial proposed ITS plan organizes the systems into expressway, ramp, arterial, and management components, each with multiple ITS systems. The ramp and expressway systems would be directly linked and coordinated. The link between arterial systems and expressway/ramp systems can be via directly coordinated systems or a linkage through policy and operations. The result would be a fully functional integrated ITS corridor. Effective management systems (i.e., software, policies, staffing) are as important to the outcomes as the addition of ITS field devices. Initial proposed ITS devices are described below.

I-290 ITS Devices

The proposed I-290 reconstruction and improvements allow the introduction of new ITS systems, such as Active Traffic Management (ATM), and opportunities to implement a next generation of the existing ITS system, which has ramp metering that has operated in the Project Corridor for years.



A central component of the I-290 system is the ITS gantry. The gantry is a multipurpose structure that can be used to hold toll rate signs, toll readers, ATM signs, dynamic message signs (DMS), and standard traffic signs. By utilizing a multipurpose gantry, the ITS design becomes a flexible and efficient way to manage a dense network of ITS systems.

The ITS systems on I-290 are dependent on having high quality real-time traffic data for system management. There are a variety of technologies available, either as in-pavement detection or nonintrusive detection systems that are placed on poles or ITS gantries. The detection systems provide real-time information on volume, speed, lane occupancy, and vehicle classification. The data from detectors can be used to set toll prices, provide

travel time and congestion messages, create vehicle classification and traffic data sets, and determine advisory speed limits, as well as run an adaptive ramp metering program. If a toll system is required, it must be interoperable with other toll systems in the Chicago region and provide national interconnectivity. It is expected that any necessary tolling equipment and signing would be accommodated within the ITS gantries.

ATM systems are a relatively new ITS system for managing traffic at the lane level. ATM lane management systems are spaced every 0.5 mile along the expressway and activated to manage reduction in speeds in advance of slowing or stopped traffic and to provide lane-level incident information to drivers (Figure 2-35). Typical messages for ATM are shown in Figure 2-36.

2.6 Conclusion – Alternatives Carried Forward for Further Analysis

The process of identifying alternatives for the reconstruction of I-290 was completed through the evaluations described previously in Rounds 1, 2, and 3.

Consideration was given to travel performance and socioeconomic and environmental effects with the intent of keeping the proposed improvements within existing right-of-way to the extent possible (see Section 3.1.7 for proposed right-of-way requirements for the build alternatives). With extensive stakeholder input, the alternatives were refined to better integrate this transportation system recognizing regional and community considerations. Consequently, the alternatives share common elements for improved roadway, transit, and other related elements, along with pedestrian and bicycle movements and noise abatement, and they share the same right-of-way footprint, interchange designs, and accommodations for the parallel CTA and CSX Railroad facilities.

With these considerations and given the design refinements described previously, the four build alternatives advanced previously for analysis in the DEIS (and this FEIS) are shown in Figure 2-37. Together with the No Build Alternative, which is used for comparison purposes, these alternatives are carried forward for detailed evaluation in Section 3.0, Environmental Resources, Impacts, and Mitigation, of this FEIS. The Preferred Alternative is presented in Section 5.0.

3.0 Environmental Resources, Impacts, and Mitigation

This section discusses the existing conditions and potential beneficial and adverse social, economic, and environmental impacts of the build alternatives. In addition, this section includes discussion of anticipated construction related impacts, a summary of potential mitigation measures, and identification of necessary permits and certifications.

This discussion is divided into the following 19 sections:

3.1 Social/Economic Characteristics 3-4
3.2 Cultural Resources 3-107
3.3 Air Quality 3-122
3.4 Traffic Noise 3-143
3.5 Energy 3-160
3.6 Natural Resources 3-162
3.7 Water Resources and Aquatic Habitats 3-173
3.8 Groundwater 3-195
3.9 Floodplains 3-198
3.10 Wetlands 3-207
3.11 Special Waste 3-208
3.12 Special Lands 3-218
3.13 Visual Resources 3-239
3.14 Construction Impacts 3-288
3.15 Indirect and Cumulative Impacts 3-298
3.16 Short-Term Use and Long-Term Productivity 3-311
3.17 Irreversible and Irretrievable Commitment of Resources 3-312
3.18 Permits and Approvals 3-314
3.19 Summary of Environmental Commitments and Mitigation 3-315

Throughout Section 3.0, the terms Study Area and Project Corridor are used to describe the following areas:

- Study Area: the approximately 55 square mile area surrounding I-290 with the northern boundary at North Avenue, the southern boundary at Cermak Road, the western boundary at the intersection of I-290 and I-294, and the eastern boundary at the intersection of I-290 and I-90.
- Project Corridor: general term covering the one mile wide area along I-290 from the I-88/290 Split in the west to Racine Avenue in the east.

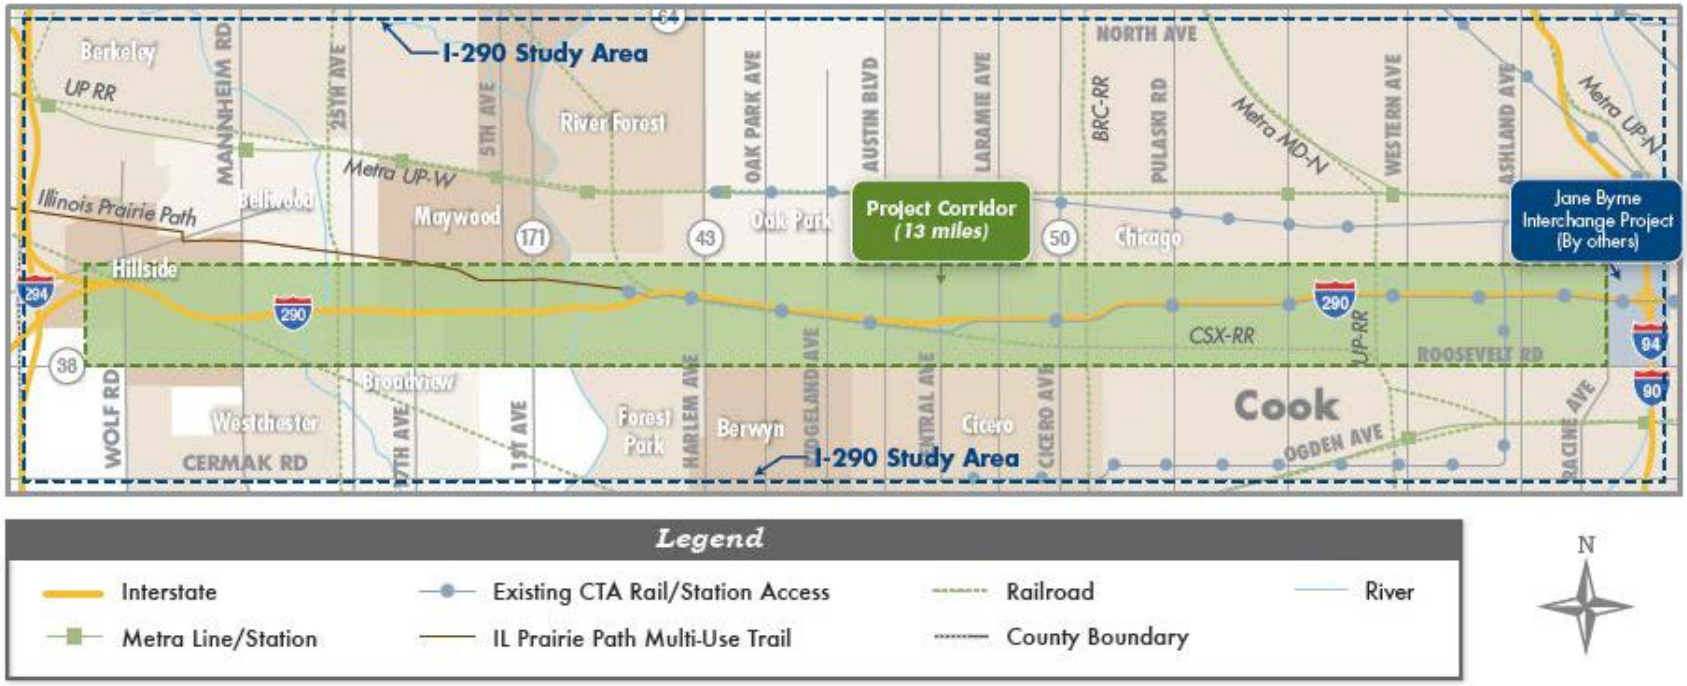

Figure 3-1 below shows the location of the Study Area and the Project Corridor (which was initially located between the intersection of I-290 and I-294 to east of Cicero Avenue, and was subsequently extended east to Racine Avenue).

Also throughout Section 3.0, the build alternatives (described in detail in Section 2.0) are identified with the following naming structure:

- General Purpose Lane Alternative (GP Lane)
- HOV 2+ Lane Alternative (HOV 2+)
- HOT 3+ Lane Alternative (HOT 3+)
- HOT 3+ Lane and Toll Alternative (HOT 3+ & TOLL)

Each of the build alternatives for the Project Corridor share the same right-of-way footprint. This footprint would require only a small amount of new right-of-way outside of the existing I-290 right-of-way area and would cause no residential, business, public facility, or other displacements or relocations.

Figure 3-1. I-290 Study Area and Project Corridor

3.1 Social/Economic Characteristics

Since publication of the Draft Environmental Impact Statement (DEIS), the following substantive changes to this section have been made:

- Clarified sources cited in Section 3.1.1 for reporting City of Chicago data in the Project Corridor;
- Updated daily vehicle hours of travel savings estimates in Section 3.1.2.2, Table 3-11;
- Updated Section 3.1.4 regarding right-of-way impacts to parking at the State of Illinois Circuit Court of Cook County Fourth Municipal District (Maywood Courthouse); and
- Updated the amount of new right-of-way in Section 3.1.7, Table 3-15 to reflect minor design changes that occurred along 1st Avenue.

This section describes and analyzes the socio-economic conditions of the Project Corridor. This assessment examines population trends, economic conditions, Environmental Justice (EJ), existing communities, traffic and transportation impacts, land use, and potential impacts caused by any of the build alternatives and the No Build Alternative.

Social and economic impacts are analyzed in accordance with the procedures of the Illinois Department of Transportation (IDOT) Community Impact Assessment Manual (IDOT, 2007), the Federal Highway Administration (FHWA) Community Impact Assessment Handbook (FHWA, 1996), and the IDOT Bureau of Design and Environment (BDE) Manual (IDOT, 2010). Generally, social and economic conditions would have minimal impact from any of the build alternatives that have been carried forward. The build alternatives each share the same right-of-way footprint and do not require relocations of any residences, businesses, or public facilities. Small areas of additional right-of-way may be required near two interchanges, which are detailed below.

3.1.1 Population Characteristics

3.1.1.1 Existing Conditions

The Project Corridor traverses highly developed areas of the Chicago metropolitan region. Communities that are either partially or wholly within the Project Corridor are listed in Table 3-1. All of the affected communities have reached a mature state and are almost fully built-out with little unused underdeveloped urban land. The communities along the Project Corridor include the following land uses: residential, commercial, industrial, recreational, and transportation.

As shown in Table 3-1, the population in Oak Park and Chicago saw moderate to substantial population decreases between 1950 and 1980, while communities farther west in the Project Corridor experienced dramatic population increases, most notably

Hillside (288.5 percent), Bellwood (126.5 percent), and Westchester (311.5 percent). From 1950 to 1980, the City of Chicago had the greatest decline in population at -38.9 percent of all communities in the Project Corridor. In the 30 years following 1980, the trend of decreasing population for cities in the eastern portion of the corridor and population increases for those communities in the western portion of the corridor stabilized. Also, the "daytime" population of Chicago increased by 177,457, according to the US Census, Commuter Adjusted Daytime Population, 2006-2010, 5-year American Community Survey (ACS). In most cases, communities in the Project Corridor experienced slight population declines from 1980 to 2012. Cicero saw the greatest increase in population between 1980 and 2012.

Table 3-1. Population Changes in Project Corridor Communities 1950-2012

Community	1950	1980	2012	% Change 1950 – 1980	% Change 1980 – 2012

Source: US Census Bureau, 2014.
Note: Numbers are rounded to 1 decimal point unless less than 0.05.
Note: Statistics are presented for the entire City of Chicago.

The total population within the Project Corridor is presented in Table 3-2.

Table 3-2. Project Corridor Population, 2010

	Project Corridor	Cook County	Illinois
Total Population	134,829	5,194,675	12,830,632

Source: US Census Bureau, 2013.

Race and Ethnicity

The overall racial and ethnic breakdown of the Project Corridor is presented in Table 3-3. The predominant racial groups in the Project Corridor are whites at 29.8 percent of the total population and African American at 58.1 percent of the total population. Population by race and ethnicity for each of the communities in the Project Corridor is presented in Table 3-4. Detailed maps showing distribution of racial groups within the Project Corridor are presented in Section 3.1.9, Environmental Justice.

Table 3-3. Project Corridor Race and Ethnicity Characteristics, 2010

	Corridor Total	Corridor %	Cook County	Illinois
White	40,306	29.9	2,877,212 (55.4%)	9,117,877 (71.1%)
Black/African American	78,526	58.2	1,287,767 (24.8%)	1,866,414 (14.5%)
American Indian/ Alaska Native	224	0.1	21,559 (0.4%)	43,963 (0.3%)

Source: US Census Bureau, 2009 – 2013 ACS.

[a] As presented in FHWA Order 6640.23A, Hispanic or Latino populations are classified as a minority group, regardless of race. Consistent with US Census data, Hispanic or Latino origins are considered as ethnicity data and a separate designation from race data.

Note: Numbers are rounded to one decimal point unless less than 0.05.

Of the communities within the Project Corridor, the Villages of Bellwood, Broadview, and Maywood are predominantly African American, while Elmhurst and Oak Park are predominantly white. The other communities in the Project Corridor also have a mix of racial groups.

Table 3-4. Population by Race and Ethnicity for Project Corridor Communities

Sources: * US Census Bureau, 2010.

US Census Bureau, 2009 – 2013 ACS.

[a] As presented in FHWA Order 6640.23A, Hispanic or Latino populations are classified as a minority group, regardless of race. Consistent with US Census data, Hispanic or Latino origins are considered as ethnicity data and a separate designation from race data.

Note: Numbers are rounded to 1 decimal point unless less than 0.05.

Populations comprising the communities of the Project Corridor are diverse, with varying levels of minority population between the communities. This variation can be seen in Oak Park, having the lowest minority population, while Cicero has the highest minority population. Taken as a whole, the communities within the Project Corridor are comprised of 86.3 percent minority population, which is higher than Cook County (68.5 percent) and the State of Illinois (44.2 percent).

> As presented in FHWA Order 6640.23A, Hispanic or Latino populations are classified as a minority group, regardless of race. According to the US Census Bureau, the terms "Hispanic" or "Latino" refer to persons who trace their origin or descent to Mexico, Puerto Rico, Cuba, Spanish-speaking Central and South America countries, and other Spanish cultures. Origin can be considered as the heritage, nationality group, lineage, or country of the person or the person's parents or ancestors before their arrival in the US. People who identify their origin as Hispanic or Latino may be of any race, consistent with FHWA Order 6640.23A, thus the Hispanic ratio was not added to percentages for racial categories.

Approximately 9.7 percent of the population of the Project Corridor considers themselves Hispanic or Latino, compared to the 24.0 percent average for Cook County and the 15.8 percent average for Illinois.

Most of the City of Chicago lies outside of the Project Corridor. To better assess the population and demographic characteristics of only the subarea of Chicago, census blocks within the 0.5-mile Project Corridor were examined to provide better detail. The racial makeup of Chicago within the Study Area has a percentage of minority populations similar to the city as a whole, with 86.3 percent of the Chicago Project Corridor subarea being minority versus 83.9 percent for all of the City of Chicago. The largest minority group within the Chicago Project Corridor subarea is African American, comprising 65.4 percent of the Chicago subarea's population.

Within the Project Corridor, populations are generally more diverse than either Cook County or the State of Illinois. Overall, the Project Corridor is just over 64.5 percent African American, compared to only 24.8 percent of Cook County, or 14.5 percent of Illinois. Hispanic/Latino populations make up a smaller percentage of the corridor population (9.7 percent) than Cook County (24 percent) or Illinois (15.8 percent).

Age

Data on ages of populations of communities in the Project Corridor are presented in Table 3-5. Five communities had higher percentages of populations of children (under age 18) than the Cook County average of 23.64 percent. The five communities are the City of Chicago within the I-290 Project Corridor (24.8 percent), Village of Bellwood (25.10 percent), Oak Park (24.89 percent), Maywood (23.92 percent), and Cicero (34.0 percent). Cicero had the highest percentage of its population under 18 of all Project Corridor communities. The average population for seniors (ages 65 +) in Cook County was 12.04 percent. Of the Project Corridor communities, Hillside (14.49 percent), Westchester (21.75 percent), Broadview (13.08 percent), Elmhurst (13.59 percent), and Maywood (12.64 percent) had higher percentages of senior populations than Cook County, with Westchester being the highest.

Table 3-5. Age Characteristics of Project Corridor Communities

Community	Total Population	% < 18	% 18-21	% 22-29	% 30-39	% 40-49	% 50-64	% 65 +
Elmhurst	44,385	21.7	6.3	6.8	10.4	16.7	18.8	13.6
Hillside	8,136	21.6	7.5	8.9	12.1	17.4	18.04	14.5

Note: Numbers are rounded to 1 decimal point unless less than 0.05.

3.1.1.2 Population Impacts

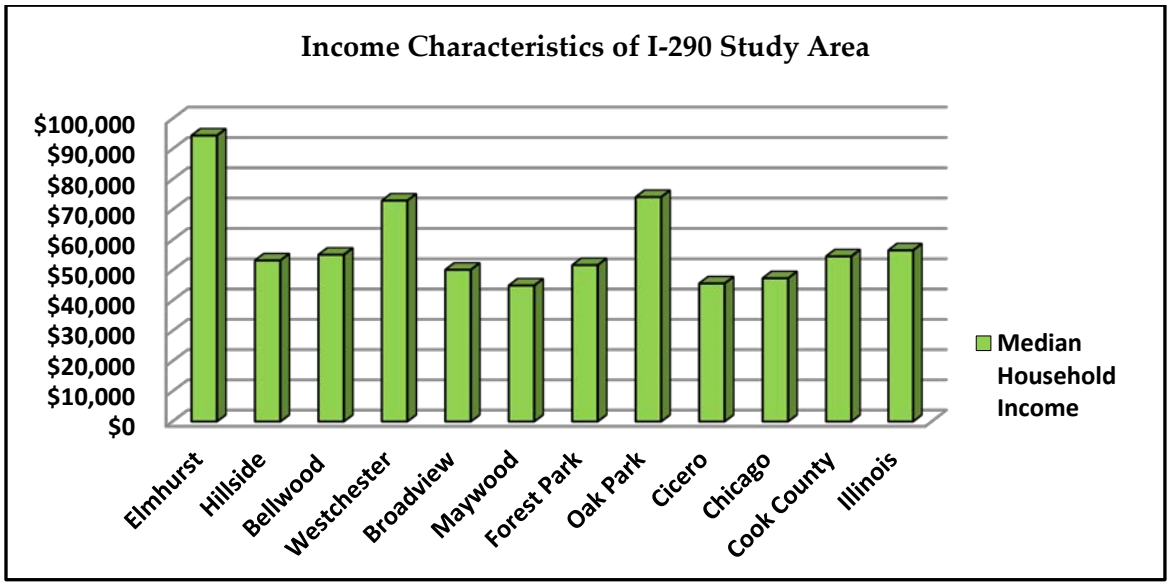
Year 2040 market-driven socio-economic forecasts were developed as part of the I-290 Study (full discussion in Section 3.15.1, Indirect and Cumulative Impacts, and Appendix B). This included both 2040 No Build and 2040 Build population forecasts. The 2040 No Build population forecasts assumed no I-290 Eisenhower Expressway improvements (no additional lanes on I-290) and no high capacity transit (HCT) extension to the west from the Chicago Transit Authority (CTA) Blue Line Forest Park station (no Blue Line Forest Park Branch extension). The 2040 No Build population forecasts assumed the implementation of other major capital transportation projects outside of the Study Area that are included in the approved, fiscally constrained, Metropolitan Transportation Plan (MTP) and Transportation Improvement Program (TIP) for the region.

The Study Area population forecast for the 2040 No Build is 649,215 persons, and for the 2040 Build Scenario, the 2040 population forecast is 651,912 persons. The build alternatives would result in an additional 2,697 persons, or a 0.4 percent increase in population.

The slight differences between the 2040 Build and No Build population forecasts are due to the transportation improvements included in the I-290 build alternatives. The increase

is small due to the existing built-out urban conditions in the Study Area and that the proposed project reflects improvements to an existing facility that already provides accessibility to the Study Area. These highway and transit improvements result in improved accessibility for the Study Area, which then affect the population forecasts. The improvement of access to developable or redevelopable sites increases the development potential of those sites, attracting development that may have occurred elsewhere in the region. Because the I-290 build alternatives include highway and transit improvements, composite accessibility effects were used to measure changes in accessibility for the build alternatives.

3.1.2 Corridor Economic Characteristics



This section provides data on current economic conditions within the Project Corridor, including employment characteristics, income levels, poverty rates, auto ownership, housing, and travel time to work.

3.1.2.1 Existing Conditions

Income and Poverty

The ACS 5-year estimates were used to compile the income characteristics of the communities for the Project Corridor. For comparative analysis, income and demographic data were gathered for Cook County and the State of Illinois. With the exception of Westchester ($72,966), Oak Park ($74,141), Elmhurst ($94,424), and Bellwood ($55,123), each of the communities has a lower median family income level than that of Cook County ($54,598) or the State of Illinois ($56,576) (Figure 3-2). Of the communities analyzed, Elmhurst had the highest median family income, while Maywood had the lowest ($44,979).

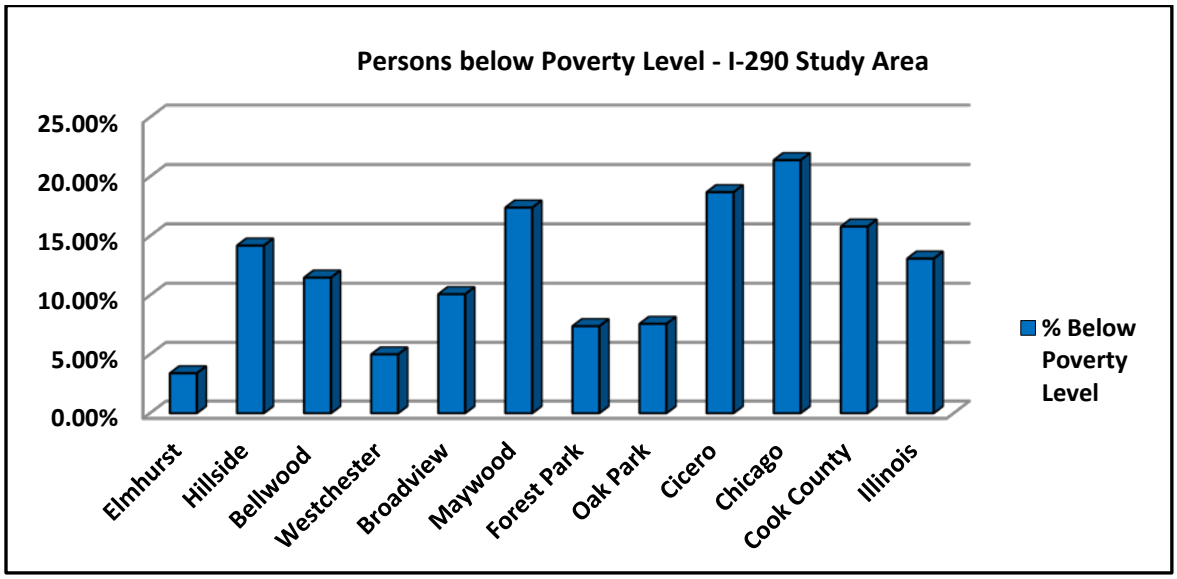


Figure 3-2. I-290 Median Household Income for Project Corridor Communities (2011)

Source: US Census Bureau, 2007-2011 ACS, 5-Year Estimates, 2013.
Note: Income statistics are for the entire City of Chicago since data were not available for only the portion of Chicago within the Project Corridor.

According to the United States Department of Health and Human Services (HHS), the poverty guidelines for 2014 are an income of $19,790 for a family of three and $23,850 for a family of four. The Poverty Guideline for individuals is an income of $11,670. The Poverty Guidelines are issued annually and serve as an administrative function for the federal government in determining eligibility for certain federal programs. Median household incomes for all core communities are higher than the poverty guidelines. Westchester and Elmhurst had the lowest percentages of persons living below the poverty line, while communities with the highest percentage of persons living below the poverty line were generally found on the eastern portion of the corridor. Chicago has the highest percentage of persons below the poverty line at 21.4 percent. Poverty information for the Project Corridor is shown in Figure 3-3. Additional discussion of low-income populations is included in Section 3.1.9, Environmental Justice.

Figure 3-3. Poverty Levels for Project Corridor Communities (2011)

Source: US Census Bureau, 2007-2011 ACS, 5-Year Estimates, 2013.

Unemployment

Unemployment numbers are shown by community in Table 3-6. Over the past decade, US Census data has shown an increase in seasonally adjusted civilian unemployment in the Project Corridor communities and Cook County. This trend is likely the result of the recent economic recession that began in 2008. Increases in unemployment rates are not localized to the Project Corridor, as seen in the national unemployment rate climbing from 4.0 percent in 2000 to 9.6 percent in 2010.[1]

[1] United States Bureau of Labor Statistics, 2013. https://data.bls.gov/timeseries/LNS14000000

Table 3-6. Project Corridor Community Unemployment Percentages 2000 – 2014

Community	Percent Civilian Workforce Unemployed 2000	Percent Civilian Workforce Unemployed 2014
Elmhurst	1.9 [a]	4.8 [c]
Hillside	4.4 [a]	6.7 [c]
Bellwood	6.5 [a]	10.3 [c]
Westchester	2.5 [a]	4.7 [c]

[b] Illinois Department of Employment and Security, October 2013.
[c] US Bureau of the Census, 2010 – 2014 ACS, 5-Year Estimate.
Note: Numbers are rounded to one decimal point unless less than 0.05.
Note: Statistics are presented for the entire City of Chicago since 2014 data were not available for the portion of Chicago within the Project Corridor.

Housing

The total number of occupied housing units within communities of the Project Corridor was 1,121,652 according to the ACS 5-year estimates (Table 3-7). In the State of Illinois, the average rate of home ownership is 68 percent, and in Cook County, it is 59 percent. Of the Project Corridor communities listed in Table 3-7, the only communities with lower percentages of home ownership than that of Cook County were Forest Park (47.4 percent), Chicago within the Project Corridor (34.1 percent), and Cicero (52.5 percent). The Village of Westchester had the highest percentage of owner-occupied homes in the Project Corridor at 91.1 percent.

Table 3-7. Housing Characteristics of Project Corridor Communities

Community	Total Occupied Housing Units	% Owner Occupied	% Renter Occupied
Elmhurst	15,307	81.4	18.6
Hillside	2,994	68.9	31.1
Bellwood	5,974	75.3	24.7
Westchester	6,381	91.1	8.9
Broadview	3,164	64.4	35.6
Maywood	7,708	63.5	36.5
Forest Park	6,894	47.4	52.6
Oak Park	21,750	62.2	37.8
Cicero	21,404	52.5	47.5
Chicago	1,030,076	46.1	53.9
Chicago (within Project Corridor)	30,377	34.1	65.9
Cook County	1,933,670	59.0	41.0
Illinois	4,774,275	68.0	32.0

Sources: US Bureau of the Census, 2008-2012 ACS 5-Year Estimates.
Note: Numbers are rounded to 1 decimal point unless less than 0.05.

Auto Ownership

The percent of autos owned per household indicates whether people rely on personal vehicles or another form of transportation (e.g., walking, bicycle, bus) to get to and from work, the grocery store, school, etc.

Within the Project Corridor communities, the only community to have a higher percentage of zero and one car households than both the State of Illinois and Cook County was the City of Chicago at 26.8 percent for zero car and 44.5 percent for one car (Table 3-8). The portion of the City of Chicago that lies within the Project Corridor 0.5-mile buffer has 31.4 percent of its population without access to a car and 48.4 percent of the population with access to one car. This indicates that 31.4 percent of households (without a car) within the Chicago portion of the Project Corridor rely on another form of transportation besides a personal car. Outside of the City of Chicago, the Project Corridor communities with the highest percentage of zero car households are Forest Park (15.8 percent) and Maywood (15.2 percent). Both are slightly below the Cook County average but higher than the statewide average.

Table 3-8. Auto Ownership Characteristics of Project Corridor Communities

Community	% 0 Cars	% 1 Car	% 2 Cars
Elmhurst	0.7	13.9	52.3
Hillside	10.6	37.8	34.3
Bellwood	8.4	37.1	34.6
Westchester	4.9	33.7	47.7
Broadview	6.9	50.1	30.4
Maywood	15.2	35.3	33.4
Forest Park	15.8	52.6	28.3
Oak Park	12.8	47.0	34.2
Chicago (within I-290 Project Corridor)*	31.4	48.4	17.0
Cicero	5.0	25.1	39.3
Chicago	26.8	44.5	22.1
Cook County	17.7	40.7	30.3
Illinois	10.7	34.9	37.2

* US Bureau of the Census 2009-2013 ACS, 5-Year Estimates.
Note: Numbers are rounded to 1 decimal point unless less than 0.05.

Travel Time to Work

Generally, travel times to work of employees within the Project Corridor communities grow longer in the eastern portions of the corridor. In the State of Illinois, the percent of employees whose travel time to work was greater than 30 minutes was 42.8 percent. For Cook County, the average was 53.6 percent. With the exception of the Village of Broadview (41.6 percent), every community in the Project Corridor had a greater percentage of its population with a 30-minute or greater travel time to work than the statewide average (Table 3-9). According to US Census 2011-2014 data, the average commuter in the Chicago metropolitan region has a one-way commute of 30 minutes, while the national average is 26 minutes.

Oak Park (61.4 percent), Cicero (55.4 percent) and Chicago (58.3 percent) were greater than Cook County and the statewide average for a 30-minute or greater travel time to work. Of all Project Corridor communities, the Village of Oak Park had the greatest percentage of its population with travel time to work at 30 minutes or higher. Of the communities in the Project Corridor (using the US Census definition of a 'long commute' as traveling 60 or more minutes to work), Forest Park has the highest percentage of long commuters at 15 percent with Elmhurst second at 11.4 percent.

Travel time to work is important to analyze because it:
- Provides an understanding how the entire transportation system serves each community getting to and from jobs;
- Is a measure of the efficiency of the transportation system; and
- Plays a role in shaping residential and commercial land use patterns (i.e., people may base their decision of where to live and work based on the convenience and duration of their commute).

A shorter travel time to work is preferred over a longer travel time.

Table 3-9. Travel Time to Work Characteristics of Project Corridor Communities

Minutes to Work	Percentage of Population											
	Illinois	Cook County	Elmhurst	Hillside	Bellwood	Westchester	Broadview	Maywood	Forest Park	Oak Park	Cicero	Chicago
Less Than 10	12.6	7.3	14.4	10.2	8.6	7.6	9.7	7.8	6.4	7.4	6.0	5.3

N/A: Not available.

Note: Numbers are rounded to 1 decimal point unless less than 0.05.

Note: Statistics are presented for the entire City of Chicago since 2014 data were not available for only the portion of Chicago within the Project Corridor.

Employment

A summary of those industries providing the greatest number of jobs in the corridor communities is presented in Table 3-10. Generally, the greatest numbers of jobs are located in the eastern portion of the Project Corridor in the communities of Forest Park, Oak Park, and Chicago. The healthcare and manufacturing industries tend to provide the largest number of jobs in the Project Corridor communities. Bolded numbers in Table 3-10 indicate the largest employment sector for each community along the Project Corridor.

The Project Corridor is home to hundreds of businesses and employers of varying types and sizes. Many of the largest employers in the corridor are medical facilities, such as the University of Illinois Medical Center (Chicago), Rush University Medical Center (Chicago), Jesse Brown Veterans Administration Medical Center (Chicago), and Loyola Medical Center (Maywood). Other large employers within the Project Corridor include Corn Products International (Westchester), Dynamic Manufacturing (Hillside), United States Postal Service Bulk Mail Facility (Forest Park), and Ferrara Candy Company (Forest Park). Corn Products International is headquartered in Westchester and processes corn, wheat, potatoes, and other raw materials to provide ingredients for food, beverage, pharmaceutical, and other industries. Corn Products International employs more than 11,000 worldwide. Dynamic Manufacturing in Hillside manufactures automotive, off-road, industrial, and racing powertrain products. The United States Postal Service Bulk Mail facility in Forest Park is part of a greater network of Network Distribution Centers located around the country used to sort and process mail for a large geographic region. The Ferrara Candy Company, directly south of I-290 at Circle Avenue in Forest Park, is a candy manufacturer best known for producing Atomic Fireballs and Lemon Heads. Each of these employers, along with other businesses in the Project Corridor, are dependent on reliable connections to local roadways, freight rail access, and I-290 to ship and receive goods and to move customers and employees to their locations.

3.1.2.2 Economic and Employment Impacts

All of the build alternatives would result in long-term benefits associated with improved access to and from I-290. In addition, the reduction in vehicle hours of travel (VHT) associated with all of the alternatives would provide productivity savings, which is measured by multiplying the travel time savings by the time value of money. The alternatives provide the following savings in daily VHT compared to the No Build Alternative (Table 3-11).

Assuming a $24 per hour value of time per the National Cooperative Highway Research Program (NCHRP) *Report 456 Guidebook for Assessing the Social and Economic Effects of Transportation Projects,* the annual benefit to productivity in 2040 would range from $83 to $152 million depending on the alternative, as shown in Table 3-11.

Table 3-10. Employment by Major Industries for Project Corridor Communities

Industry	Elmhurst	Hillside	Bellwood	Westchester	Broadview	Maywood	Forest Park	Oak Park	Cicero	Chicago	Cook County
All Industries Total	27,554	5,489	3,145	7,795	7,674	9,181	5,217	14,312	15,383	1,088,765	2,095,533
Manufacturing	1,973	**936**	**1,491**	144	**3,151**	415	**1,049**	197	2,773	63,074	188,427
Wholesale Trade	3,445	728	245	302	1,244	128	199	115	1,992	36,501	100,774
Retail Trade	2,347	516	189	253	677	98	1,000	953	486	90,128	224,306
Transportation & Warehousing	612	423	121	20	329	228	A/	24	92	60,328	111,375
Finance and Insurance	1,596	131	45	925	33	29	105	470	328	103,217	142,393
Professional, Scientific & Tech Services	1,795	394	17	1,038	39	49	79	959	125	138,046	199,214

Accommodations & Food Service	1,940	418	154	287	173	**455**	711	1,800	1,102	110,257	206,848

Source: Illinois Department of Employment and Security, 2013. Where Workers Work 2014.

A/ = Numbers omitted to avoid disclosure of individual data.

BOLD: Indicates largest employment sector for each community.

Note: Statistics are presented for the entire City of Chicago since data were not available for only the portion of Chicago within the Project Corridor.

Table 3-11. Alternatives Daily Vehicle Hours of Travel Savings and Annual Productivity Benefits Change vs. No Build Alternative

Build Alternatives	GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
Daily Vehicle Hours of Travel Change	-9,840	-9,773	-16,161	-17,300
2040 Annual Productivity Change	$83 Million	$86 Million	$142 Million	$152 Million

Changes caused by the build alternatives are not anticipated to generate substantial new areas of developable land along the Study Area. With the proposed construction of a single-point urban interchange (SPUI) at the interchange at 25th Avenue, the existing ramps to the northwest, southwest, and southeast of the interchange would be removed. The quadrants to the south would then be used for stormwater management areas. The area northwest of 25th Avenue and I-290 could be available for future development.

Employment Impacts

Year 2040 market-driven socio-economic forecasts were developed as part of the I-290 Study (full discussion in Section 3.15.2.1). This included 2040 No Build and 2040 Build employment forecasts. The 2040 No Build population forecasts assumed no I-290 Eisenhower Expressway improvements (no additional lanes on I-290) and no HCT extension to the west from the CTA Blue Line Forest Park Station (no Blue Line Forest Park Branch extension). The 2040 No Build employment forecasts assumed the implementation of other major capital transportation projects outside of the Study Area that are included in the approved, fiscally constrained, MTP and TIP for the region.

The Study Area employment forecast for the 2040 No Build is 309,334 jobs, and for the 2040 Build Scenario, the 2040 employment forecast is 310,967 jobs, or a 0.5 percent increase in employment. This relatively small increase is due to the existing built-out urban conditions in the Study Area and that the proposed project reflects improvements to an existing facility that already provides accessibility to the Study Area.

The differences between the 2040 Build and No Build employment forecasts are due to the transportation improvements included in the I-290 build alternatives (full discussion in Section 3.15.1, Indirect and Cumulative Impacts, and Appendix B). These highway and transit improvements result in improved accessibility for the Study Area, which then affect the employment forecasts. The improvement of access to developable or redevelopable sites increases the development potential of those sites, attracting development that may have occurred elsewhere in the region. Because the I-290 build alternatives include highway and transit improvements, composite accessibility effects were used to measure changes in accessibility for the build alternatives.

3.1.3 Project Corridor Neighborhoods

3.1.3.1 Existing Conditions

Residential neighborhoods exist along the entire length of the Project Corridor, with many of these neighborhoods directly adjoining the Eisenhower Expressway. Neighborhoods in the Project Corridor are well established and include single- and multi-family housing, which has developed in a fairly compact pattern. These neighborhoods are served by a full range of community services, including hospitals, schools, libraries, parks, commercial/retail, churches, police, fire, post offices, public transit, and many others that are detailed in Section 3.1.4, Public Facilities and Services.

For the purposes of this Final Environmental Impact Statement (FEIS), the term "neighborhood" refers to the portions of the nine communities plus the City of Chicago that are fully or partially within the Project Corridor. From west to east these neighborhoods are the City of Elmhurst; Villages of Hillside, Bellwood, Westchester, Broadview, Maywood, Forest Park, and Oak Park; the Town of Cicero, and the City of Chicago. Brief summaries of each neighborhood, as well as graphics depicting the neighborhood's place in the Project Corridor, are detailed below.

Existing land uses throughout the Project Corridor are presented in Figure 3-4 through Figure 3-7. Overall, residential uses are the primary land use throughout the Project Corridor, making up slightly less than 30 percent of the total land use. Non-parcel and unclassified right-of-way comprises the second largest overall land usage with approximately 26 percent of total usage. Non-parcel right-of-way is typically composed of roadways. The third largest land use in the Project Corridor is Civic and Institutional usage (e.g., hospitals, schools, churches, cemeteries, government) at just over 13 percent. In general, the entire Project Corridor is mostly built out, with only four percent of the current land use vacant for residential, commercial, or industrial usage.

City of Elmhurst

The City of Elmhurst was incorporated in 1882. In 2010, Elmhurst had a population of almost 43,000 (US Census Bureau, 2010). Although not directly adjacent to I-290, Elmhurst is located at the westernmost edge of the Project Corridor's 1-mile-wide corridor. Only a small portion of Elmhurst falls within the Project Corridor. The southeasternmost portion of Elmhurst is in the Project Corridor. This very small portion of the city is all residential land uses.

Figure 3-4. Existing Land Use – I-290 Study Area (Subarea 1)

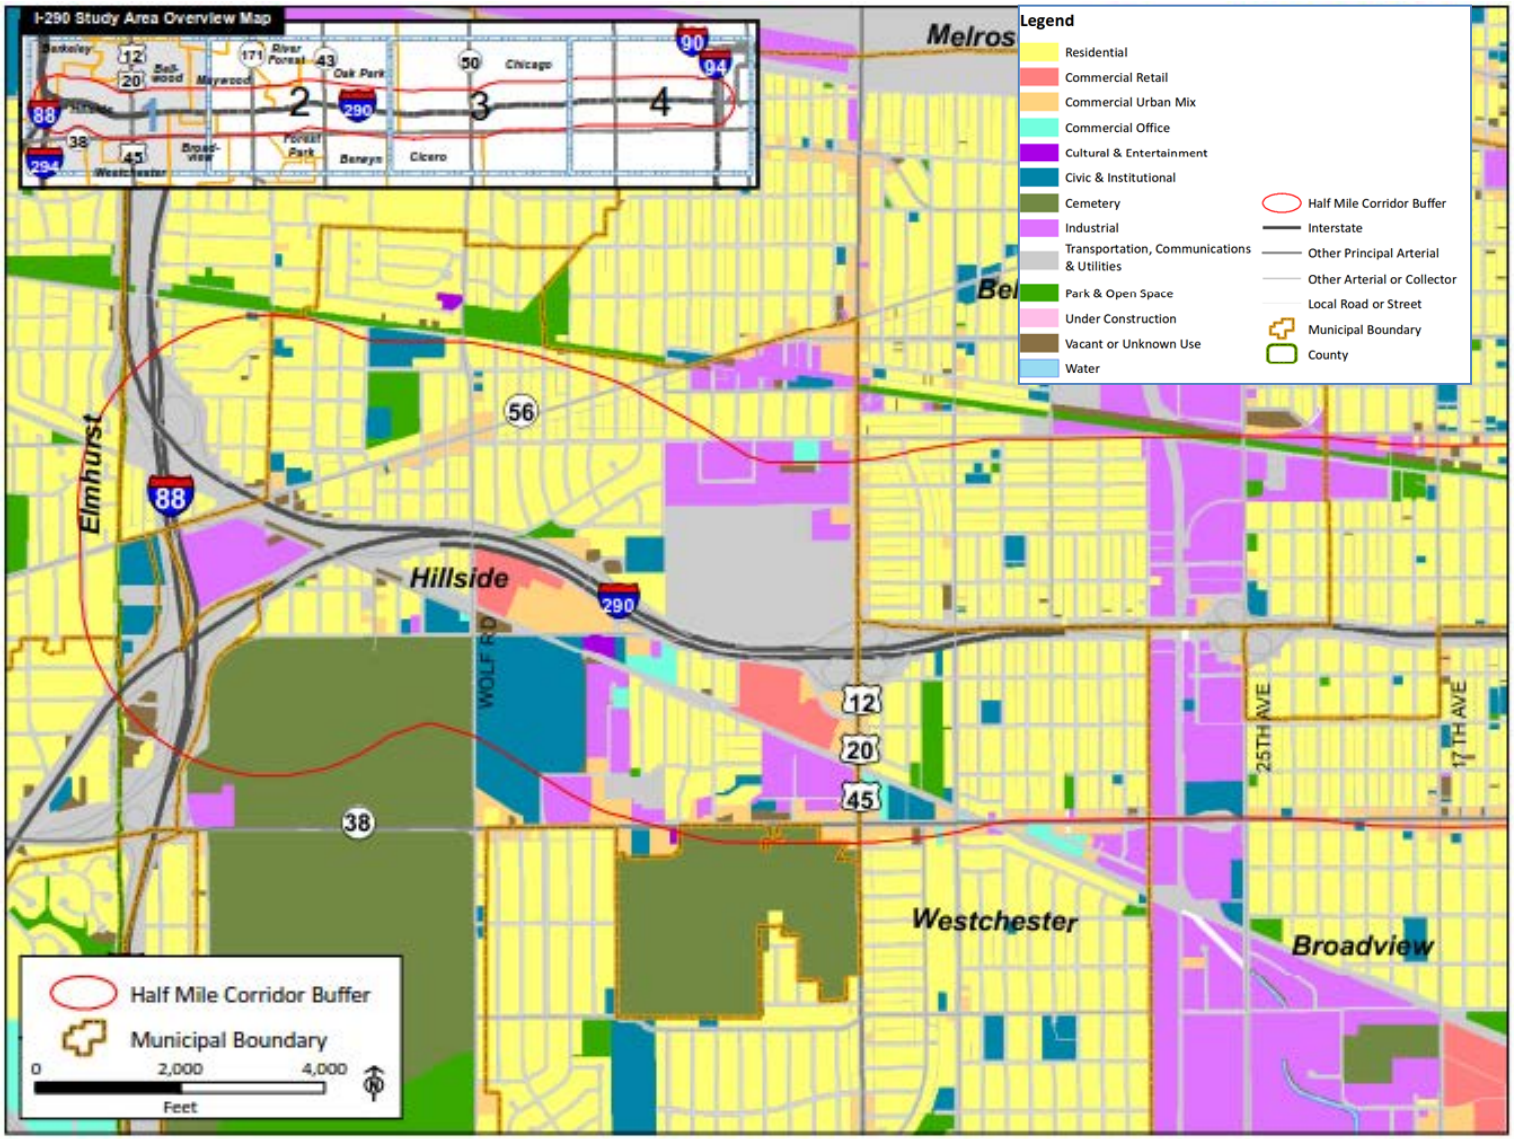

Figure 3-5. Existing Land Use – I-290 Study Area (Subarea 2)

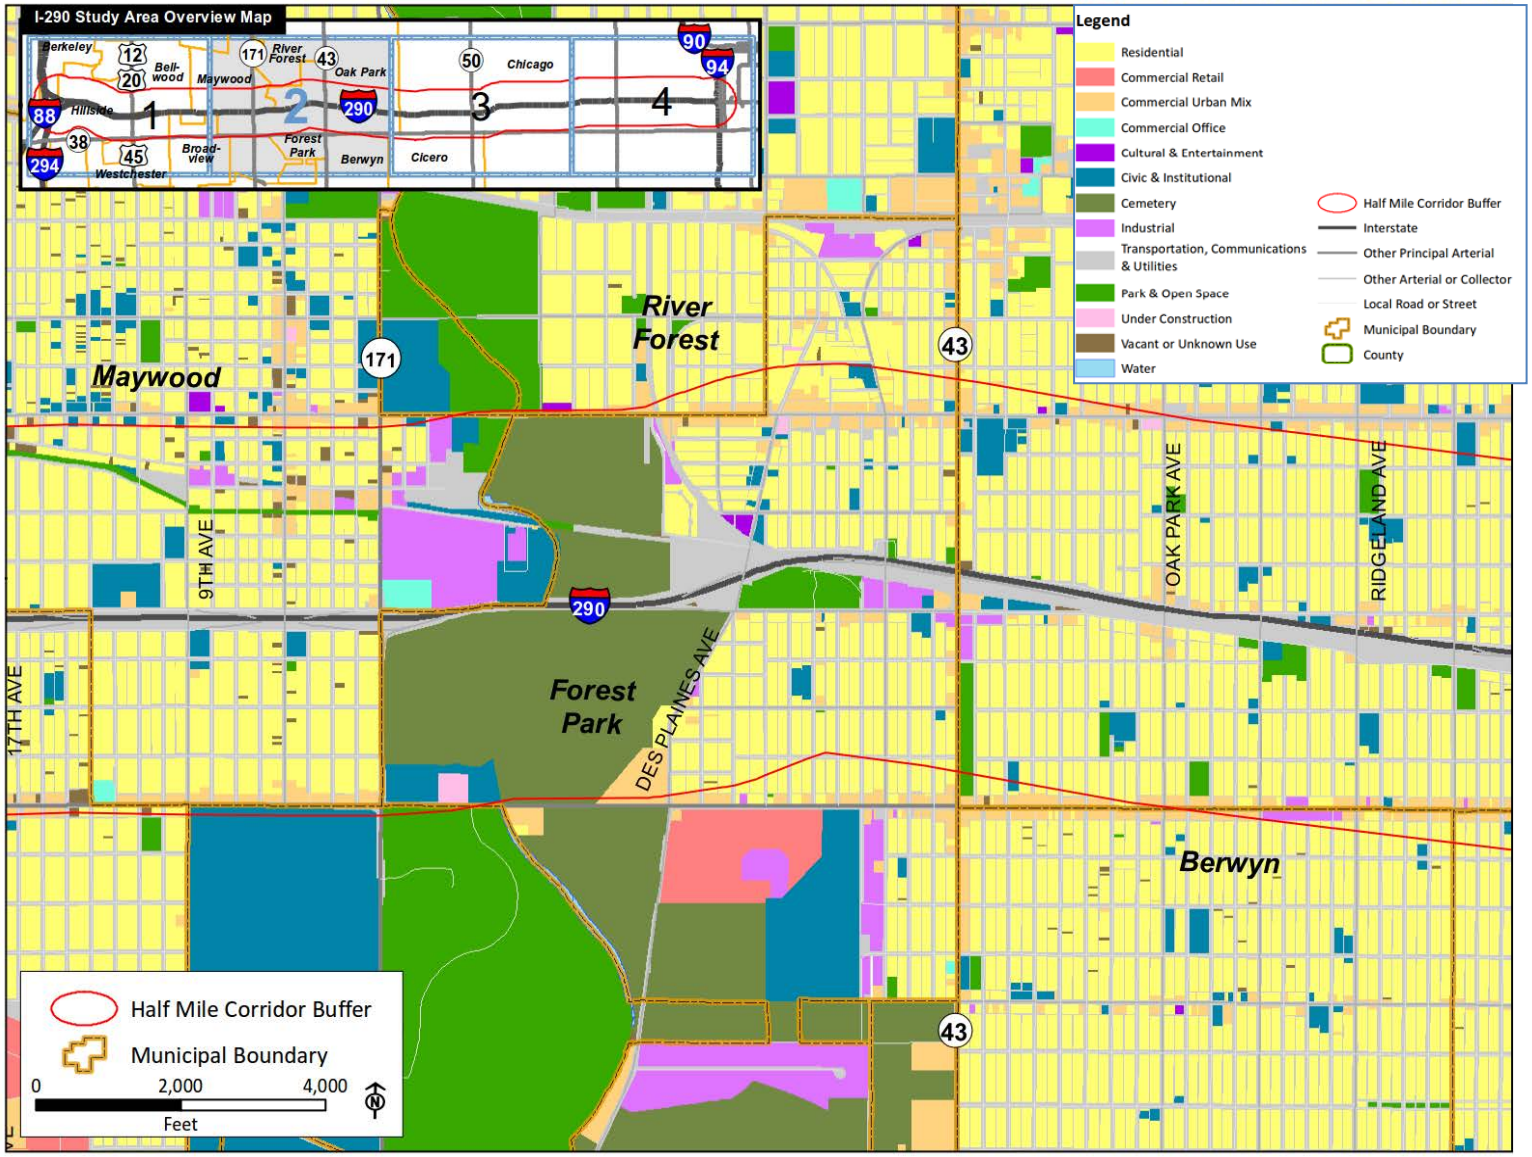

Figure 3-6. Existing Land Use – I-290 Study Area (Subarea 3)

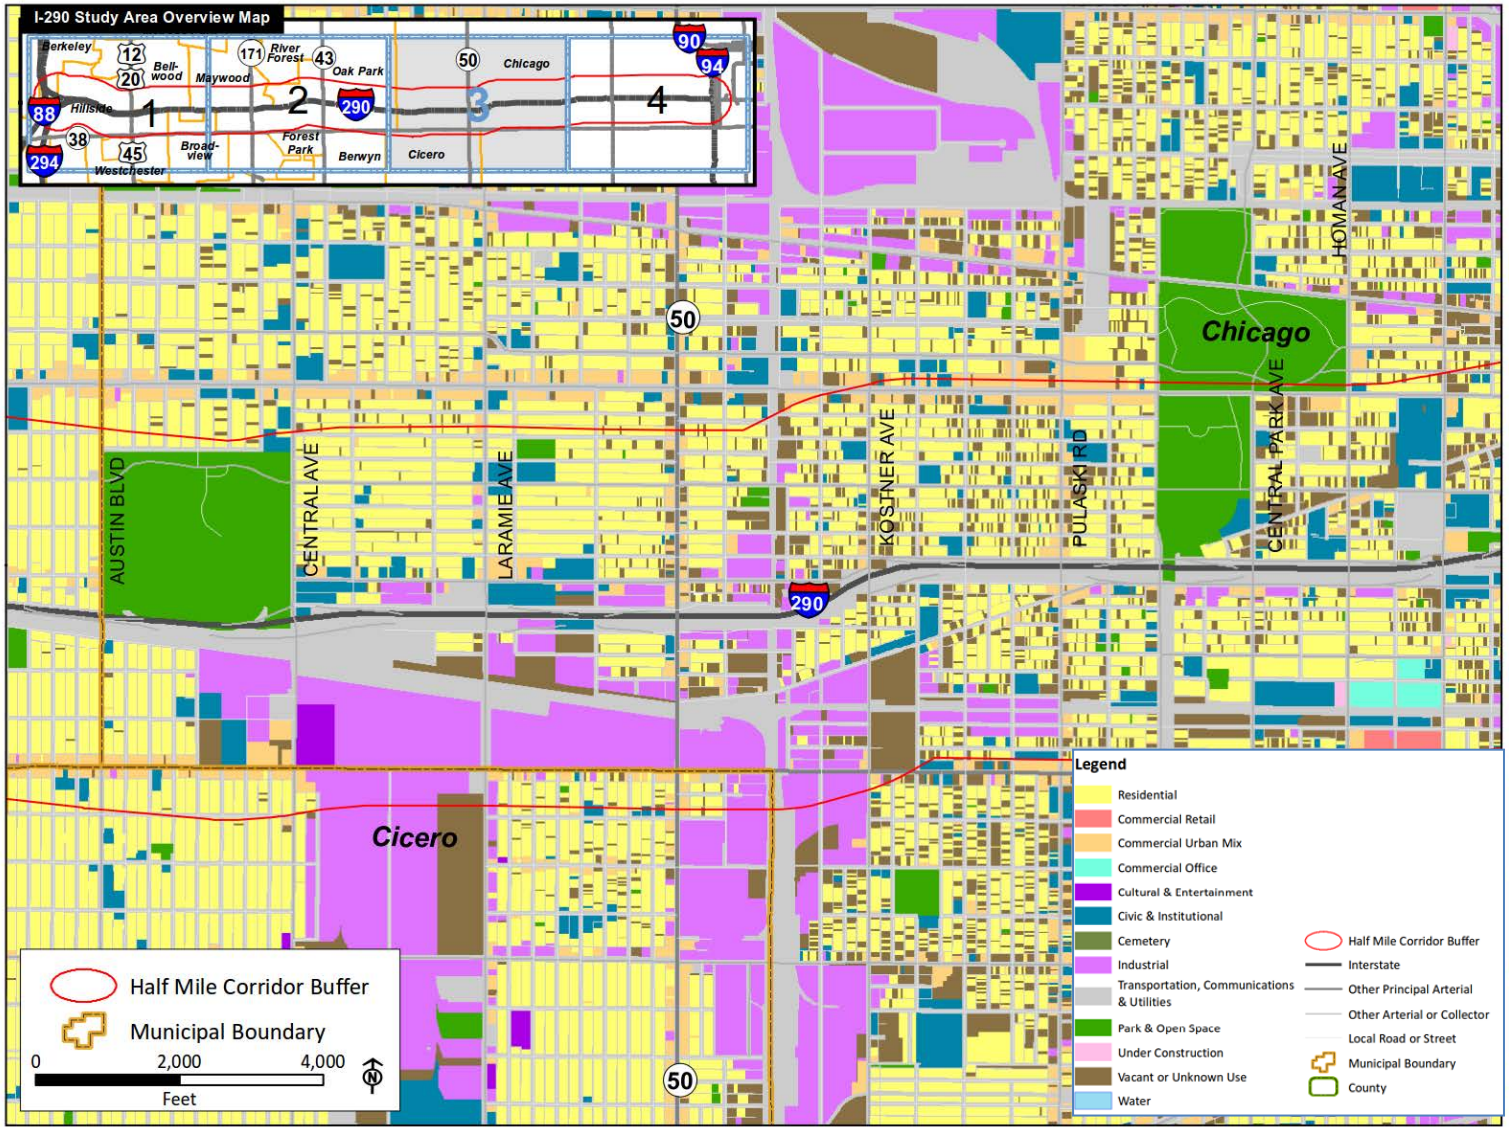

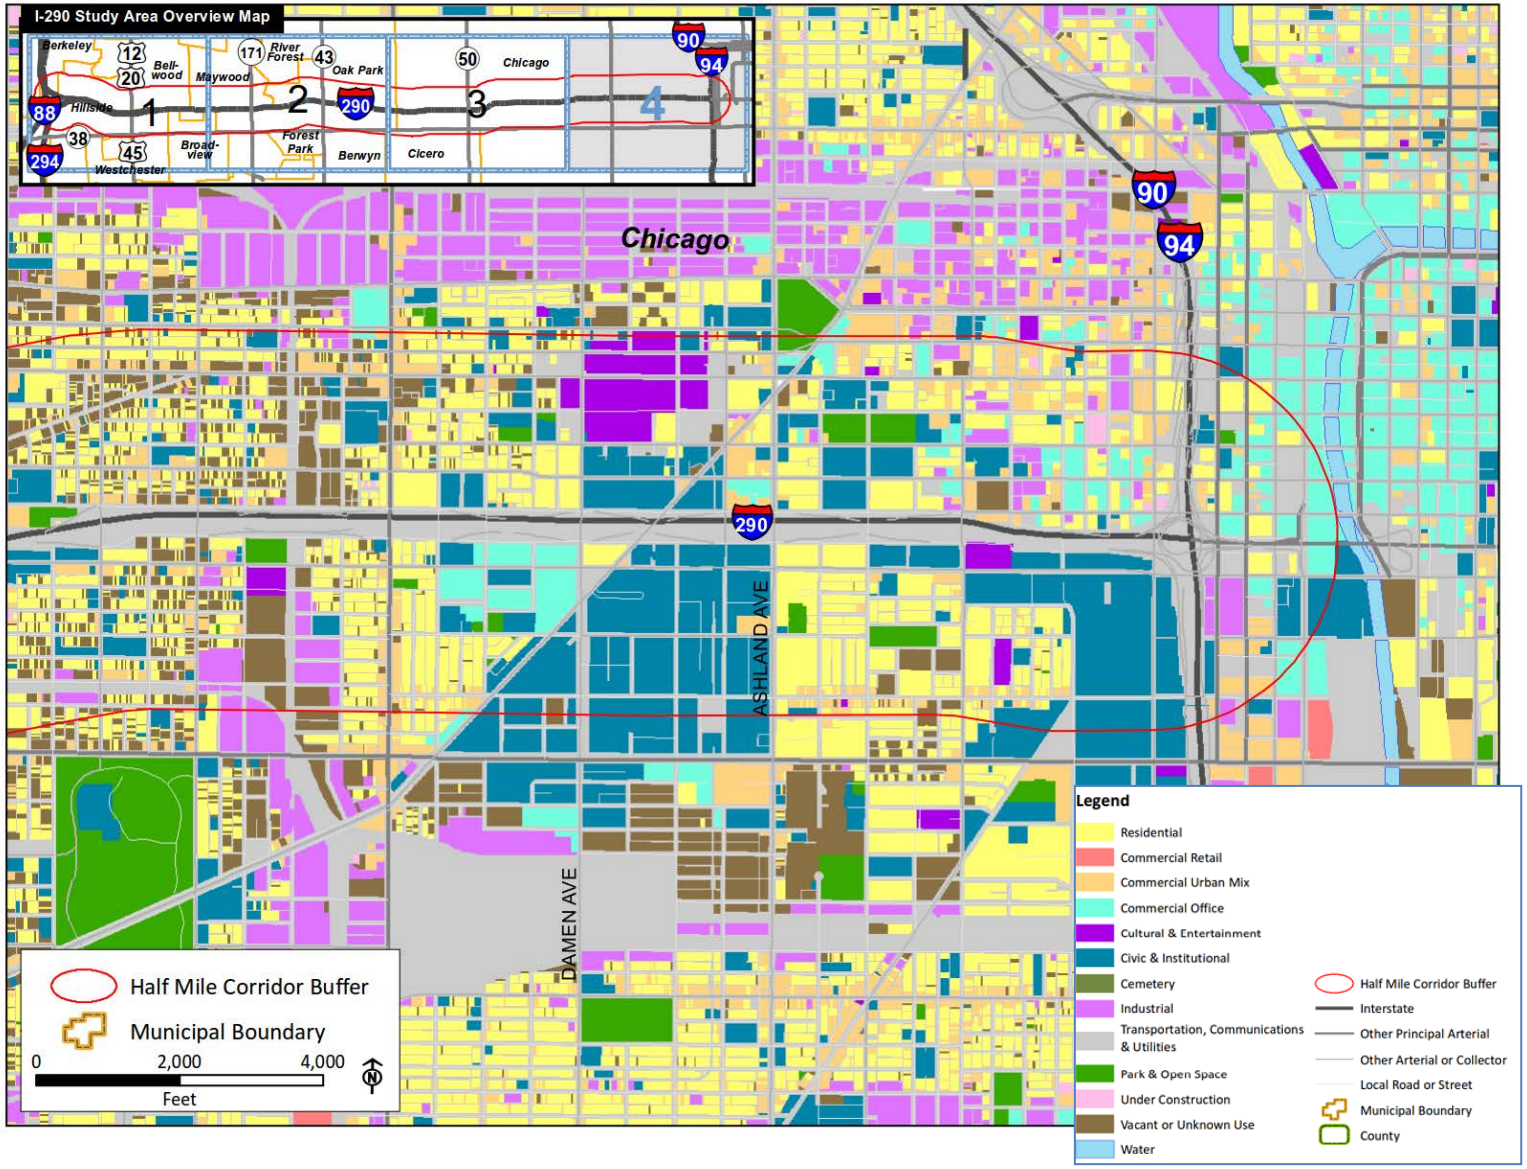

Figure 3-7. Existing Land Use – I-290 Study Area (Subarea 4)

Village of Hillside

The Village of Hillside was established in 1905 and had a population of 8,157 in 2010 (US Census Bureau, 2010). The village has an approximate land area of 3.2 square miles and sits on the northwestern edge of the Project Corridor near the convergence of I-290, I-294, and I-88. The Project Corridor extends approximately 1.7 miles through Hillside. The Village of Hillside's main point of access to I-290 is at Mannheim Road (US Route 12/20/45).The land uses in Hillside that are adjacent to I-290 vary as the facility crosses the village from west to east. An industrial district exists on the far western edge of the village close to where I-290 and I-88 converge. Single-family and multi-family land uses exist on the north and south sides of I-290 in the west/central area of Hillside. South of I-290 at Wolf Road, there is a large commercial development with a Menards hardware store and Car Max auto dealership. Opposite this commercial district, on the north side of I-290, are two hotels. Near the intersection of Mannheim Road and the Project Corridor, the land north of the expressway is vacant, but it is zoned for office and limited industrial uses. Southwest of I-290 and Mannheim Road is retail big box development, such as Target, Petco, and Michaels.

Village of Bellwood

The Village of Bellwood is located east of the Village of Hillside in the northwest portion of the Project Corridor. Bellwood sits north of I-290 with a portion of the expressway forming its southern boundary from 22nd Avenue to Mannheim Road and extends approximately 1.25 miles through Hillside. The Village of Bellwood was formally incorporated in 1900. In 2010, the village's population was 19,071 (US Census Bureau, 2010). The village's Comprehensive Plan states its total land area at 2.3 square miles. Bellwood's main point of access to I-290 is at the Mannheim Road (US Route 12/20/45) interchange and 25th Avenue.

Land uses directly adjoining the I-290 right-of-way are predominantly single-family residences. At the northwest corner of the interchange of I-290 and 25th Avenue is a business/light industrial area. Located northeast of the 25th Avenue interchange is the vacant Wilson Elementary School building and more single-family residences.

Village of Westchester

The Village of Westchester is located in the southwest area of the Project Corridor, south of I-290. The village was founded in 1924 and has a total land area of 3.69 square miles, with a 2010 population of 16,718 (US Census Bureau, 2010). Only a small northeastern portion of the village between Mannheim Road to the west and Gardner Road to the east directly abuts I-290 for an approximate distance of 0.8 mile. This area is generally a mix of commercial uses and single-family residences. The primary access point for the Village of Westchester to I-290 is at Mannheim Road (US Route 12/20/45).

Village of Broadview

The Village of Broadview is located directly east of the Village of Westchester on the south side of I-290. The Village of Broadview was formally incorporated in 1914. I-290 forms the northern boundary of the village from Gardner Road to South 25th Avenue

and from South 17th Avenue to South 13th Avenue. The overall land area of Broadview is 1.3 square miles,[2] with a population of 7,932 (US Census Bureau, 2010). Broadview's main access points to I-290 are at South 25th Avenue and South 17th Avenue. The two separate portions of Broadview that share right-of-way with I-290 have a combined distance of approximately 0.5 mile.

The two primary areas of Broadview that directly abut I-290 have two distinct land uses. The area between Gardner Road and 25th Avenue is zoned for office and industrial uses, while the area of Broadview between 17th Avenue and 13th Avenue is mostly comprised of single-family residences and some commercial uses along 17th Avenue.

Village of Maywood

The Village of Maywood was established in 1881. As of 2010, the village's population was 24,090 (US Census Bureau, 2010) with an approximate land area just under 3 square miles. The Village of Maywood is located in the west-central portion of the Project Corridor and is bounded on the east by the Des Plaines River, on the south by the Village of Broadview, on the north by Melrose Park, and on the west by the Village of Bellwood. Most of the village is located north of I-290, but two small portions are located south of the expressway. The approximate length of I-290 through Maywood is 2 miles.

The primary land uses adjacent to I-290 are single-family residential. Multi-family uses are found along 5th Avenue directly south of I-290. North of I-290, along 1st Avenue (Illinois Route 171) is a commercial district. Northeast of 1st Avenue and I-290 is the Maywood Town Center, Cook County Sheriff's office, Circuit Court of Cook County – Fourth Municipal District Courthouse, and Cook County Clerk's office.

Maywood has four main access points to I-290 located at South 25th Avenue, South 17th Avenue, South 5th Avenue, and South 1st Avenue.

Village of Forest Park

The Village of Forest Park was established in 1884 and is located in the central portion of the Project Corridor. Portions of the village are located on the north and south sides of the expressway. The total land area of Forest Park is 2.4 square miles according to the US Census Bureau. Much of that area is taken up by three large cemeteries located in Forest Park: Forest Home, Waldheim, and Concordia. Forest Park had 14,167 residents in 2010 (US Census Bureau, 2010).

The Forest Home Cemetery is located directly south of I-290, west of 1st Avenue and east of DesPlaines Avenue. Directly north of I-290, between the Des Plaines River on the west and Van Buren Street on the east, is Concordia Cemetery.

North of I-290 and west of DesPlaines Avenue is the terminus station and park-and-ride for the CTA Blue Line.

[2] Village of Broadview. http://www.broadview-il.gov/common.php?id=16.

Single-family residential areas are found in Forest Park directly north of I-290 between DesPlaines Avenue and the eastern boundary of the village at Harlem Avenue. South of I-290 between DesPlaines Avenue and Circle Avenue is the village's municipal offices and parks. South of Harrison Street are single- and multi-family residences. Major access points to I-290 in Forest Park are at DesPlaines Avenue and Circle Avenue. The approximate length of I-290 through Forest Park is 1.5 miles.

Village of Oak Park

The Village of Oak Park is located centrally along the Project Corridor, directly west of the City of Chicago. Oak Park was established in 1902 and had a total population of 51,878 in 2010 (US Census Bureau, 2010). The total land area for Oak Park is 4.7 square miles. The main points of access for Oak Park to I-290 are located at Harlem Avenue and Austin Boulevard. The approximate distance of I-290 through Oak Park is 1.6 miles.

On the north and south sides of I-290 through Oak Park, the primary land use is residential, which varies from single-family homes to higher density multi-family uses along Oak Park Avenue, Harrison Street, and Austin Boulevard.

Several parks in proximity to I-290 in Oak Park include Rehm Park located between East Avenue and Gunderson Avenue, Barrie Park between Lombard Avenue and Taylor Avenue, the Elsie Jacobsen Discovery Garden at the Oak Park Conservatory between Clarence Avenue and East Avenue, and the Wenonah Tot Lot located at Wenonah Avenue and Harrison Street.

Town of Cicero

The Town of Cicero was established in 1857 and had a population of nearly 84,000 residents in 2010 (US Census Bureau, 2010). Cicero is located south of I-290 and shares its eastern border with the City of Chicago. Only the northernmost edge of Cicero is located within the Project Corridor. Within this portion of Cicero, along Roosevelt Road, land uses include industrial, transportation, and residential.

City of Chicago

The City of Chicago was founded in 1837. Today, Chicago is the third largest city in the US with a population of 2,695,598 (US Census Bureau, 2010). The city's total land area is approximately 234 square miles. The I-290 expressway is one of several major transportation corridors providing access to and from downtown Chicago. Chicago accounts for approximately 46 percent of the overall Project Corridor, or approximately 6 miles.

Chicago has multiple access points to I-290, including (from west to east):

- Austin Boulevard;
- South Central Avenue;
- South Laramie Avenue;
- South Cicero Avenue;

- South Kostner Avenue;
- South Independence Boulevard;
- South Homan Avenue;
- South Sacramento Boulevard;
- South California Avenue;
- South Western Avenue;
- South Oakley Boulevard;
- South Damen Avenue;
- South Paulina Street;
- South Ashland Avenue; and
- South Racine Avenue.

Land uses in Chicago along the Project Corridor vary widely as the facility moves from Austin Boulevard on the west into the downtown loop where I-290 connects with I-94 and I-90 on the east end of the Project Corridor. At the western edge of Chicago, between Austin Boulevard and Central Avenue, is Columbus Park along the north side of I-290. The park was created in the early 1900s and is approximately 135 acres in size.

South of I-290, between Central Avenue and Kostner Avenue, is a large manufacturing district. On the north side of I-290 from Central Avenue east to Hamlin Boulevard is largely residential uses. Residential uses are also predominant south of I-290 from Kostner Avenue east to Western Avenue.

The Illinois Medical District is located south of I-290, west of Ogden Avenue, and east to Ashland Avenue. This medical district is home to several major hospitals in the region, including John H. Stroger Cook County Hospital, Rush University Medical Center, University of Illinois Medical Center, and Jesse Brown VA Medical Center.

Southwest of the confluence of I-290, I-90, and I-94 on the eastern end of the Project Corridor in Chicago is the University of Illinois – Chicago (UIC). The UIC campus is generally located between Racine Avenue on the west and I-94 on the east, extending south to approximately 16th Street.

A major attraction in this area is the United Center, located approximately 0.3 mile north of I-290 between Damen Avenue and Wood Street. The United Center is home to the Chicago Bulls and Chicago Black Hawks, as well as hosts of numerous events throughout the year attracting thousands of visitors. A new practice facility is also being completed north of I-290 at South Damen Avenue.

The northeasternmost portion of the Project Corridor in Chicago is a dense mix of residential and commercial uses from Ashland Avenue east to I-90.

3.1.3.2 Impacts to Neighborhoods and Land Use

Each of the build alternatives would not result in any changes to the existing surrounding land uses. Access to and from I-290 would be maintained, with the exception of four ramps between 1st Avenue and 25th Avenue. Because the build alternatives do not require large areas of new right-of-way, the permanent impacts to the areas surrounding I-290 would be minimal. In many cases, improvements to traffic flow, pedestrian access, and bicycle access would help enhance residential and commercial land uses along the Project Corridor.

3.1.4 Public Facilities and Services

3.1.4.1 Existing Conditions

This section provides a summary of the existing public facilities and services within the Project Corridor. For the purposes of this analysis, public facilities include schools, hospitals, emergency services (police/fire), places of worship, cemeteries, parks, recreation centers, libraries, and other municipal/government facilities such as city halls and post offices. Specific impacts to parks, recreation facilities, and other special land uses are discussed in greater detail in Section 3.12, Special Lands. Information used to locate public facilities was gathered through secondary sources, city/village websites, and field visits. The Section 3.0 Map Set shows the public facilities within the Project Corridor.

There are 271 public facilities and services located within the Project Corridor (Table 3-12). The most common facility types found in the Study Area are churches (137) and schools (68). Most of these facilities are located in the eastern half of the Project Corridor, within the City of Chicago.

Table 3-12. Public Facilities/Services in the Project Corridor

Facility	Elmhurst	Hillside	Bellwood	Westchester	Broadview	Maywood	Forest Park	Oak Park	Cicero	Chicago (within the Project Corridor)	Total
Schools	0	4	2	1	1	4	4	5	3	44	68
Libraries	0	1	0	0	0	0	1	1	0	3	6
Parks	0	0	1	1	0	0	1	7	0	23	33

Total	0	11	4	7	9	17	18	25	3	176	271

Source: WSP Parsons Brinkerhoff, 2013.

While the number of cemeteries found in the Project Corridor is relatively low (three), the location of these cemeteries is worth noting. On the western edge of the Study Area, Mount Carmel Cemetery is located near the I-294/I-290 interchange at 1400 South Wolf Road in the Village of Hillside. The Village of Forest Park has two sizable cemeteries that are adjacent to I-290. The 230-acre[3] Forest Home Cemetery established in 1876 is located on the south side of I-290 at 863 DesPlaines Avenue. Directly north of I-290 and Forest Home Cemetery is Concordia Cemetery located at 7900 Madison Street in Forest Park.

Schools

The communities along the Project Corridor are served by multiple public schools, private schools, colleges, and universities. There are 10 public school districts within the Project Corridor that are detailed in Table 3-13. Many of these school districts serve multiple communities in the Project Corridor and are largely made up of elementary and middle schools.

Table 3-13. School Districts Serving Project Corridor Communities

School District	School Type	Project Corridor Community Served
Hillside School District 93	Elementary, Middle School, High School	Hillside
Proviso Township District 209	High School	Maywood, Broadview, Forest Park, Bellwood, Hillside
Bellwood School District 88	Elementary, Middle School	Bellwood, Hillside, Maywood, Broadview
Westchester School District 92-5	Elementary, Middle School	Westchester, Broadview
Lindop School District 92	Elementary, Middle School	Broadview
Maywood-Melrose Park-Broadview School District 92	Elementary, Middle School	Maywood, Broadview
Forest Park School District 91	Elementary, Middle School	Forest Park
Oak Park District 97	Elementary	Oak Park
Oak Park & River Forest District 200	High School	Oak Park
Chicago School District 299	Elementary, Middle School, High School	Chicago

Three higher education institutions are located at the eastern end of the Project Corridor in the City of Chicago. The largest of these is UIC, located south of I-290 and west of I-90/I-94, in western Chicago. As of the 2015 fall semester, UIC had a total enrollment of 29,048 students.[4] Rush University and Rush University Medical Center are located

[3] Forest Home Cemetery. 2013. http://www.foresthomecemetery.net/.

[4] University of Illinois at Chicago. 2015. UIC Key Facts. www.uic.edu/uic/about/keyfacts/index.shtml.

directly south of I-290 at 600 South Paulina Street in Chicago and have approximately 2,000 students.[5] The third higher education institute located in the eastern portion of the Study Area is Malcolm X College, located directly north of I-290 at 1900 W. Jackson Boulevard in Chicago. Malcolm X College, hosting 5,000 students per semester,[6] is one of seven colleges that make up the City Colleges of Chicago network.

Religious Institutions

As shown in the Section 3.0 Map Set, there are numerous religious institutions scattered within the Project Corridor. These religious institutions represent a diverse range of denominations and vary in congregation size. The greatest concentration of religious institutions is located in the eastern portion of the Study Area, in the City of Chicago. Within the Chicago portion of the Project Corridor, there are nearly 100 religious institutions. Outside of the Chicago portion of the Study Area, the highest number of religious institutions is located in Maywood (11), Oak Park (9), and Broadview (8).

Medical and Public Safety Services

Within the Project Corridor, there are nine major hospitals serving local residents and the greater Chicago metropolitan area. Loyola University Medical Center is just outside the southern edge of the Project Corridor, but due to its size and high volume of visitors (more than 1.38 million[7]), it was included in this analysis. According to the Illinois Department of Public Health, Loyola University Medical Center is the only designated trauma center in the Project Corridor. Hospitals located in the Project Corridor are listed in Table 3-14. The John H. Stroger, Jr. Hospital of Cook County has the highest number of emergency room visits with almost 110,000 annually.[8] Along with serving the medical needs of the surrounding communities, these medical centers also serve as economic generators for the local areas by employing large numbers of people.

Table 3-14. Major Hospitals / Medical Centers in the Project Corridor

Hospital Name	Type of Facility	Size (# of Beds)	Annual Patients (2012)	Number of Employees*
University of Illinois Hospital 1740 W. Taylor Street Chicago, IL 60612	General medical and surgical hospital	483	• Admissions: 17,984 • Outpatient Visits: 486,828 • Emergency Room Visits: 42,190	Full Time: 509 Part Time: 957

* *Many hospital's physicians and dentists are not on staff. They are paid as faculty by a medical school or through other arrangements and may not be included in this total.*

[9] US News and World Report. 2013. US News Best Hospitals 2013-14. http://health.usnews.com/best-hospitals/rankings

Located in the southeastern portion of the Project Corridor is the Illinois Medical District (IMD). The District consists of 560 acres of medical research facilities, labs, biotech business incubators, raw development areas, universities, and more than 40 health care-related facilities.[10]

Fire Protection

Each of the communities in the Project Corridor has its own municipal fire department providing fire protection and emergency medical services. Fire stations within the Project Corridor are identified in the Section 3.0 Map Set. All of the Project Corridor communities are part of the Mutual Aid Box Alarm System (MABAS). The MABAS allows all member communities' fire and emergency services to work together in situations where emergency events overwhelm the capabilities of local emergency services. The Villages of Oak Park and Forest Park are in MABAS Division 11. The Villages of Bellwood, Broadview, Hillside, Maywood, and Westchester are in MABAS Division 20. The City of Chicago makes up MABAS Division 9. There are 10 fire stations located within the Project Corridor.

Police

Police protection and law enforcement is provided by each of the municipalities in the Project Corridor. There are five law enforcement stations within the Project Corridor, including municipal police stations, Cook County Sheriff's Office, and Illinois State Police (ISP). The ISP has 21 divisions across the State of Illinois, with the Chicago District providing highway and expressway protection and enforcement in Cook County.

Courts

The State of Illinois Circuit Court of Cook County Fourth Municipal District (Maywood Courthouse) at 1500 Maybrook Drive in Maywood is one of six Circuit Court facilities in Cook County, and serves the western suburbs of the county.

3.1.4.2 Impacts to Public Facilities and Services

No impacts to public facilities and services would occur with the No Build Alternative, although growing congestion along local streets, arterials, and the Eisenhower Expressway may be anticipated to occur over time as traffic volumes increase. The build alternatives would only impact parking capacity at the State of Illinois Circuit Court of Cook County Fourth Municipal District (Maywood Courthouse). Approximately 27 parking spaces would be impacted due to right-of-way required for widening the I-290 Expressway; however, reconfiguration of the parking area is anticipated to result in the permanent loss of only 17 parking spaces. Cook County will be compensated for loss of parking space in accordance with IDOT land acquisition policy (Section 3.1.7.2).

Improvements to interchange performance and travel times with all of the build alternatives would improve emergency access to many areas. Improvements in accessibility associated with local traffic volumes on the local street network were also

[10] Illinois Medical District Commission. 2013. http://www.imdc.org/.

evaluated based on the proposed access modifications and mainline improvements to I-290. Overall, it was determined the average local road network daily vehicle miles traveled (VMT) would be reduced for the GP Lane and HOT 3+ Alternatives, though increased for the HOV 2+ and HOT 3+ & TOLL Alternatives. Generally, the overall VMT reduction can be attributed to the capacity and operational improvements on I-290 that would shift regional, non-local pass-through trips onto the newly reconstructed expressway. These regional, non-local pass-through trips currently use the local network to bypass expressway traffic. Section 3.1.8.2, Impacts to Transportation, provides a more detailed description of future highway and local road network conditions.

3.1.5 Local Planning

3.1.5.1 Existing Conditions

This section describes the scope and status of planning documents for the multiple communities along the Project Corridor, along with a brief description of each community within the Project Corridor. Each community has been analyzed to assess the current planning, land use, and zoning policies and how they relate to the build alternatives.

Metropolitan Transportation Plan

The region's Metropolitan Planning Organization (MPO), the MPO Policy Committee, is responsible for reviewing and programming projects that use federal transportation dollars. In 2014, the MPO adopted an updated MTP. The plan update's primary transportation emphasis is to bring the transportation system to a state of good repair, but it contains a handful of major capital projects that would maximize regional benefits of mobility and economic development.[11] The fiscally constrained projects in the plan update include expressway additions. The I-290 Eisenhower project is included in the expressway addition list.

Village of Hillside

The Village of Hillside has a comprehensive plan, but the most recent formally adopted plan was developed in 1976.

Village of Westchester

In June 2014, the Village of Westchester finalized an update of its comprehensive plan. For the most part, single-family residential and commercial uses are currently found in Westchester in the Project Corridor.

While no specific plans are noted relating to the I-290 project alternatives, the comprehensive plan does state a desire for the Village of Westchester to reach out to

[11] Chicago Metropolitan Agency for Planning (CMAP). 2014. *GO TO 2040 Plan Update Summary.* pp. 20. http://www.cmap.illinois.gov/about/2040/update.

IDOT to identify improvements to state-owned routes running throughout the community.[12]

Village of Bellwood

In 2013, the Village of Bellwood adopted its first village-wide comprehensive plan. An important goal of this plan is to maintain and enhance access to the Project Corridor to attract new business and employers to the village.

Land uses near the Project Corridor are largely residential, consisting of single-, or two-family residential dwellings. There are some small pockets of multi-family residential along Bellwood Avenue. West of 25th Avenue and north of I-290 is a business park used for light industrial and manufacturing purposes.

The Village of Bellwood sees the reconstruction of the I-290 at the 25th Street interchange as a significant opportunity to develop a signature street in the community and to provide an attractive gateway into Bellwood.

Village of Broadview

The Village of Broadview completed its most recent comprehensive plan update in April 2006. Areas of Broadview within the Project Corridor are largely single-family residential and office/industrial areas.

The central goal of the comprehensive plan related to transportation issues is to maintain and enhance the high-quality transportation opportunities that are available to Broadview residents.[13] The Plan recommends improvements to its 17th Street corridor to improve access to I-290 for residential and truck traffic. Outside of this goal, there are no specific plans listed for the Project Corridor. Each of the proposed I-290 build alternatives include a reconstructed interchange at the 25th Street interchange and maintaining current access to and from the east at the 17th Street interchange in Broadview. Therefore, each of the build alternatives would conform to the Village of Broadview's 2006 Comprehensive Plan.

Village of Maywood

The Village of Maywood's Comprehensive Plan was adopted in December 2014. The central transportation goal of Maywood's Comprehensive Plan is to support regional access and circulation through multimodal mobility.[14] The Plan recommends that Maywood stay involved in the I-290 planning process to ensure that their needs and desires are heard.[15]

[14] Ibid. p. 8.5.

[15] Ibid. p. 8.5.

Village of Forest Park

In December 2014, the Village of Forest Park updated its community-wide Comprehensive Plan. The Comprehensive Plan outlines the goals and vision for the Village for the coming 15 to 20 years. The plan states that the I-290 Eisenhower Expressway provides essential regional connections, but it is a pronounced barrier for bicyclists and pedestrians because the few streets that cross over the expressway are not hospitable to walking and bicycling.[16]

In relation to Transportation Goals related to I-290, the Plan identifies multimodal improvement goals along DesPlaines Avenue, Circle Avenue, and Harlem Avenue. Along DesPlaines and Circle avenues, the plan calls for the Village to continue working with IDOT on potentially widening these streets as part of the I-290 reconstruction to improve overall travel safety and provide better accommodations for bicyclists and pedestrians[17]. With respect to providing improved access to the CTA Blue Line, the Plan calls for the Village to continue working with IDOT and CTA to ensure that the Village takes advantage of the proposed project. The Village should make significant improvements for pedestrian and bicycle safety, and maximize access convenience to the transit stations.[18]

Village of Oak Park

The current Village of Oak Park Comprehensive Plan, *Envision Oak Park*, was adopted in September 2014. Planning for improvements or changes to the Project Corridor were issues of high importance in the final document.

The *Envision Oak Park Comprehensive Plan* sets as a goal to make the 'Eisenhower Transportation Corridor safe, convenient, and reliable with multimodal options that support environmental sustainability and livable communities.'[19] To achieve this goal, *Envision Oak Park* sets four objectives:

1. Ensure that the Eisenhower Expressway supports both local and regional travel needs and improves public transit access to destinations to the west of Oak Park;
2. Maintain the existing expressway footprint, soften the visual barrier, and preserve the established built form, character, and historic assets;
3. Improve nonmotorized mobility across the Eisenhower corridor by widening bridge sidewalks to safely accommodate bicycles and pedestrians and create small areas of open space; and
4. Explore and test creative solutions for managing transportation patterns, integrating all modes of travel, and designing infrastructure in order to maximize mobility and minimize impacts on surrounding neighborhoods.[20]

[16] Village of Forest Park. 2014. Village of Forest Park Comprehensive Plan. p. 50.
[17] Ibid p. 101.
[18] Ibid p.102.
[19] Village of Oak Park. Envision Oak Park - Comprehensive Plan. p. 148. 9/15/14.
[20] Village of Oak Park. Envision Oak Park - Comprehensive Plan. p. 148-149. 9/15/14.

Most of the land uses in the Project Corridor in Oak Park are single-family or multi-family residential uses, with commercial uses along Garfield Street and Oak Park Avenue. It is the Village's desire to maintain these neighborhoods and minimize negative impacts on the Project Corridor to the greatest extent possible. The Plan suggests that as improvements to the Project Corridor are considered, Village government should work closely with IDOT, CTA, and Pace to see that project alternatives generated would comply with the newly adopted comprehensive plan. This would help maintain the character of its neighborhoods surrounding the Project Corridor and continue to advocate for the goals outlined in *Envision Oak Park.*

City of Chicago

The City of Chicago does not have a current city-wide comprehensive master plan. The most recent comprehensive plan for the City of Chicago was adopted in 1966. Chicago does have several citywide plans, such as the *Nature and Wildlife Plan, Adding Green to Urban Design Plan*, and *Transit Friendly Development Guide*, but none that relate directly to the I-290 Study. The City of Chicago also has multiple area plans that are highly focused on specific areas. The *Near West Area Plan* (2009) is the only one of these area plans with proximity to the Project Corridor. The I-290 Eisenhower Expressway is the southern boundary of the Near West Study Area. This plan is largely focused on land use issues within the Study Area, and it does not include any specific recommendations for improvements to the Project Corridor.

3.1.5.2 Impacts to Local Planning

The build alternatives comply with regional and local comprehensive plans. All of the build alternatives conform to the recommendations, goals, and priorities of *GO TO 2040.*[21] Not all of the Project Corridor communities address I-290 in their comprehensive plans; however, below is a discussion of how the community plans are consistent with the Project:

- The Village of Hillside: The Hillside Comprehensive Plan is from 1976 and does not discuss I-290.
- The Village of Westchester: The build alternatives are consistent with the Village of Westchester's comprehensive plan, which seeks to create a multimodal transportation system in Westchester that enables the use of transit, bicycling, and walking for daily trips.
- The Village of Bellwood: The build alternatives are consistent with the Village of Bellwood's comprehensive plan.
- The Village of Broadview: Each of the build alternatives includes a reconstructed interchange at the 25th Avenue interchange and maintains current access at the 17th Avenue interchange in Broadview. Therefore, each of the build alternatives would conform to the Village of Broadview's 2006 Comprehensive Plan.

[21] Chicago Metropolitan Agency for Planning (CMAP). 2014. *GO TO 2040 Plan Update Summary.*

- The Village of Maywood: The build alternatives would comply with the Village of Maywood's Comprehensive Planning documents. In addition, the proposed 1st Avenue interchange improvements are consistent with the Village of Maywood's redevelopment plans.
- The Village of Forest Park: The build alternatives are consistent with Forest Park's Comprehensive Plan, which calls for the Village to continue working with IDOT on the potential to widen these streets as part of the I-290 reconstruction to improve overall travel safety and provide better accommodations for bicyclists and pedestrians.
- The Village of Oak Park: While the specific improvements in the build alternatives are not discussed in Oak Park's Comprehensive Plan, many of the goals and objectives expressed in the Plan are in line with the outcomes sought by all of the proposed project alternatives.
- City of Chicago: The Chicago Comprehensive Plan is from 1966 and does not discuss I-290 because it focused mainly on land use.

3.1.6 Community Cohesion and Community Changes

3.1.6.1 Existing Conditions

The existing Project Corridor is extensively developed with a diverse mix of land use typical of a major metropolitan center. While the Eisenhower Expressway is one of several primary east-west transportation arteries in the western Chicago land region, it was constructed approximately 60 years ago as one of the earliest sections of the Interstate Highway System. Its inception as a major east-west transportation facility was influenced, in part, by Daniel Burnham and Edward H. Bennett's 1909 *Plan of Chicago,* which proposed a west side boulevard along Congress Street to connect the city to the western parks and the suburbs beyond the Chicago city limits. Over the following decades, City plans preserved the West Side route right-of-way for future expressway developments. Later, the City's 1940 Comprehensive Superhighway Plan included a West Side route along the Congress Street alignment and was the City's first priority in establishing a comprehensive superhighway system. After World War II, the Congress Expressway route followed the proposed West Side route and Garfield Park "L" through Chicago, the "L" and railroad right-of-way through Oak Park and Forest Park, and continued near the alignment of Congress Street through the western suburbs, dipping south of Harrison Street through Maywood, Broadview, Bellwood, and Westchester. In Hillside, construction angled northwest through the countryside to the present day location of the I-290/I-294/I-88 interchange. The Congress Expressway opened in sections between 1955 and 1960. A large extent of impacts to community cohesion, consequently, occurred with the original construction of the Eisenhower Expressway as now reflected by the project's setting.

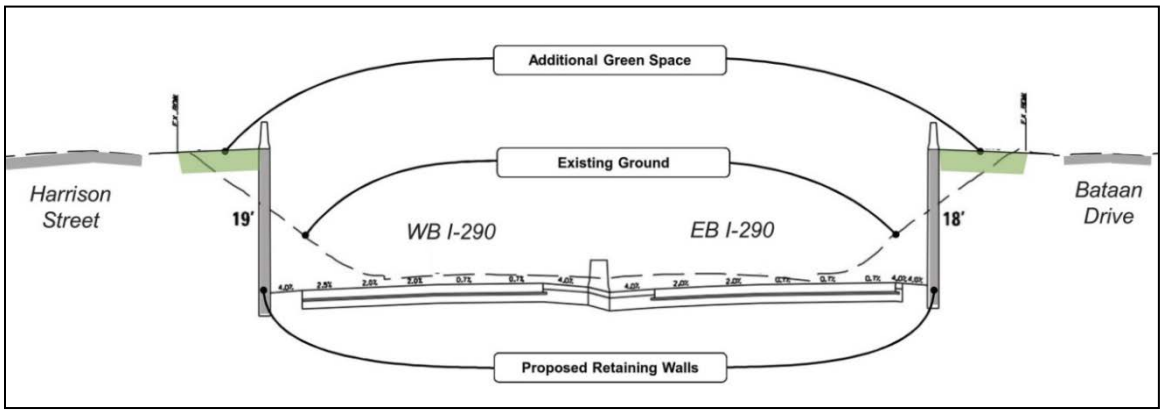
Many of the proposed improvements are intended to improve community cohesion and the urban environment. Design features include expanded/widened cross-road bridge sidewalks; pedestrian plaza areas; Americans with Disabilities Act (ADA)-compliant sidewalks and street crossings; additional green spaces; and a shared-use path extension of the regional Illinois Prairie Path trail. The proposed I-290 build alternatives would

improve safety of the traffic operations on the Eisenhower Expressway for local residents and interstate commuters, as well as improve access to existing transit facilities and bus/rail transfers. In addition, proposed noise barriers, landscape and streetscape improvement opportunities, created green spaces, and improved aesthetic appearance would help restore the overall quality of life in each of the communities.

3.1.6.2 Impacts to Community Cohesion and Community Changes

The No Build Alternative would not change the communities since no infrastructure improvements would be completed. This section provides a summary of the proposed changes at the community level. For additional reference, a summary of the proposed interchange types is provided in Section 2.5.2, Interchange Type Selection and Refinement Summary, and a more detailed explanation of the interchange design, analysis, operational evaluations, and selection process is provided in the I-290 Phase I Combined Design Report.

Each of the build alternatives for the Project Corridor share the same right-of-way footprint. This footprint would require only a small amount of new right-of-way outside of the existing I-290 right-of-way area and would cause no residential, business, public facility, or other displacements or relocations.



The existing I-290 affects community cohesion by historically separating communities to the north and south of the highway. All of the proposed build alternatives would improve community cohesion by providing wider crossings for motorized and nonmotorized travel, safer access to and from the expressway, and improved traffic flow on north-south arterials at the major interchanges.

For all of the build alternatives, some residents would experience changes in noise levels; however, most of the properties evaluated for noise impacts have existing noise levels that exceed the Noise Abatement Criteria (NAC) and, for most of these properties in the corridor, there would be no perceptible difference in noise levels between the projected 2040 No Build condition and the build alternatives. For areas where noise walls were found to be reasonable and feasible, the affected residents and property owners were provided an opportunity to vote on whether a noise wall in their area should be implemented (through a viewpoint solicitation process in accordance with IDOT policy). See Section 3.4, Traffic Noise, for a more detailed discussion of traffic noise analysis and mitigation.

Edges and Green Space

The proposed mainline design provides several plans for expanded green space areas (flat, unpaved areas at the community level next to the expressway), additional sidewalk and pedestrian plaza spaces, and additional shared-use path space. The green spaces are generally accommodated where some alignment shifts and new retaining walls are proposed within the existing right-of-way that would convert existing expressway side slopes into flat green space areas that can provide additional opportunities to local communities. Figure 3-8 illustrates how new green space area is accommodated behind the proposed expressway retaining walls. This illustration is for the expressway section between 25th Avenue and 1st Avenue, but the concept is similar for other new green space areas provided adjacent to the expressway.

Figure 3-8. New and Additional Green Space Typical Section

Source: WSP Parsons Brinckerhoff, 2016.

Overall, there is a combined total 12.99 acres of new edge and green space provided by the proposed project. The 12.99 acres consists of 7.36 acres of additional green space, 2.75 acres of additional sidewalk area and pedestrian plaza space, and 2.88 acres for the shared-use path. The expanded green space and sidewalk areas can be utilized by the communities for edge treatment improvements that could include improved landscaping, hardscaping, park space, or other community uses.

Villages of Bellwood, Broadview, and Maywood

Within the expressway section between 25th Avenue and 1st Avenue, approximately 4.65 acres of new edge and green space are provided. Approximately 3.84 acres of new green space would be added along the north and south side of I-290 between the frontage roads and the proposed I-290 retaining walls, and 0.81 acre of additional sidewalk and pedestrian plaza areas would be added along the reconstructed crossroad bridges. Within the three communities in the section, the additional edge and green space area provided is: Bellwood (0.33 acre), Broadview (0.42 acre), Maywood (3.90 acres).

Village of Forest Park

Within the Village of Forest Park, approximately 2.16 acres of new edge and green space would be created adjacent to, and over the expressway. Approximately 0.62 acre of green space area would be added along the north side of I-290 between the CSX railroad bridge and Circle Avenue, and between Circle Avenue and Harlem Avenue (between the proposed Harlem Avenue interchange ramp and the frontage road). In addition to the green space area, approximately 0.64 acre and 0.90 acre of new sidewalk and shared-use path area would also be created associated with the reconstructed crossroad bridges.

Village of Oak Park

Within the Village of Oak Park, the proposed design results in approximately 4.87 acres of edge and new green space area along the north side of I-290 between the proposed I-290 retaining wall and the adjacent frontage roads, and over the expressway along the reconstructed crossroads. Approximately 1.98 acres of new green space area would be created, along with 1.98 acres of shared-use path (parallel to I-290) and 0.91 acre of additional sidewalk and pedestrian plaza areas.

City of Chicago – Columbus Park

In the City of Chicago, 1.31 acres of new edge and green space areas is being created within the proposed mainline Reconstruction Section of the corridor associated with the proposed Austin Boulevard and Central Avenue interchange improvements adjacent to Columbus Park. Approximately 0.39 acre of new sidewalk and pedestrian plaza areas would be created as part of the reconstructed crossroad bridges, and 0.92 acre of additional greenspace would be created along the south edge of Columbus Park.

Public Services/Facilities

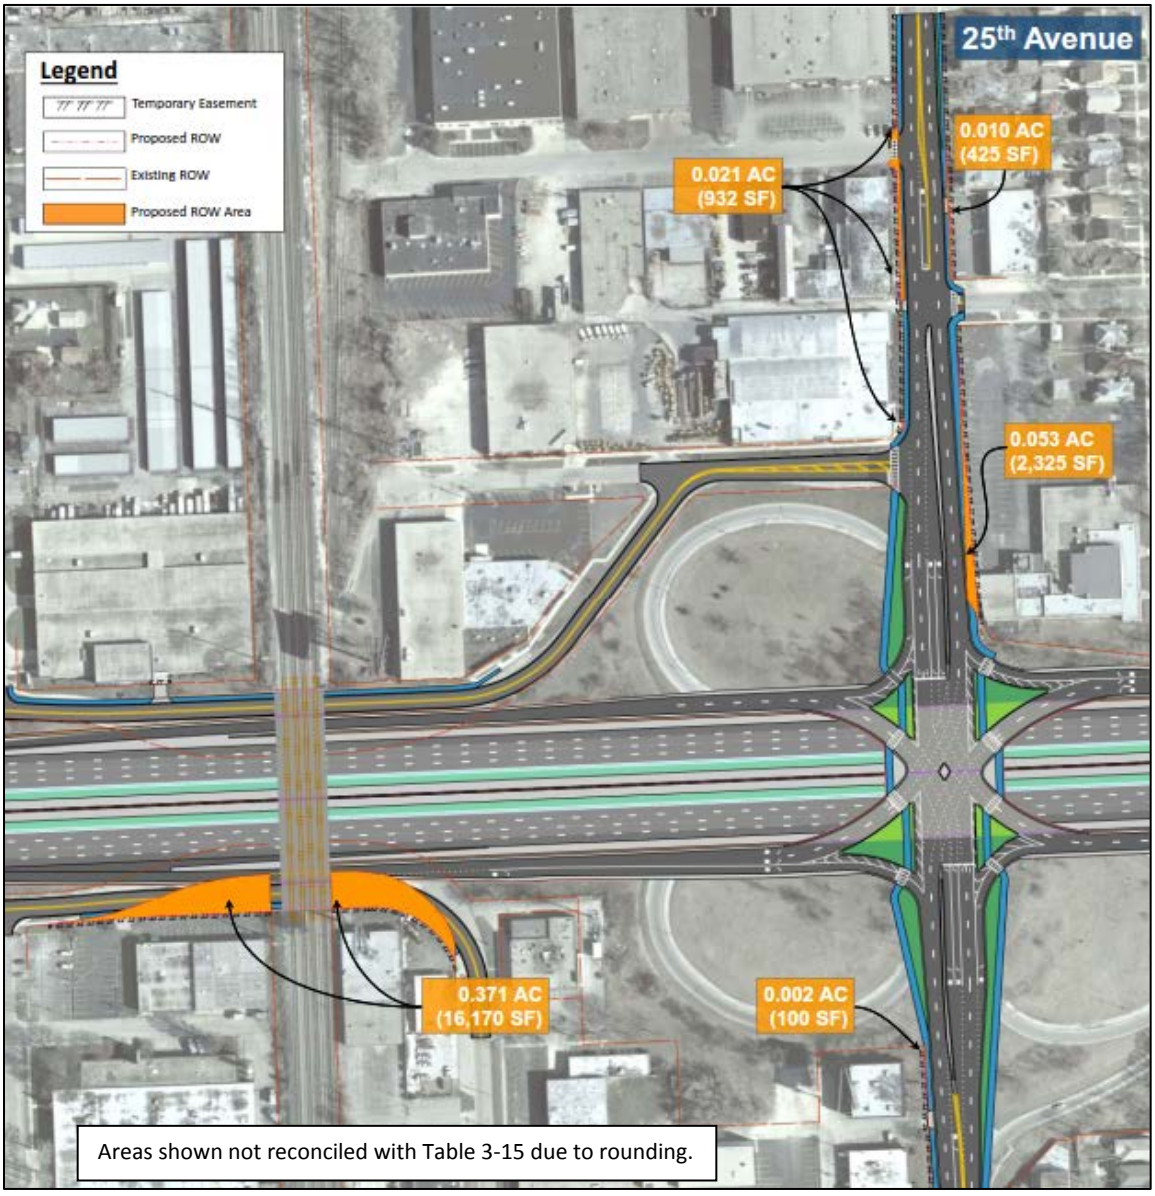
As with fire and ambulance services, any build option selected for the Project Corridor would need to be closely coordinated and planned with local, county, and state law enforcement agencies to ensure access is maintained to I-290 throughout the construction phases. The build alternatives are not expected to result in impacts to public services/facilities.

3.1.7 Relocations and Right-of-Way

3.1.7.1 Existing Conditions/Impacts

Within the 13-mile-long Project Corridor, the proposed project would require approximately 5.972 acres of right-of-way including right-of way by ownership and permanent easements, primarily associated with expressway and interchange improvements at 25th Avenue, 1st Avenue, DesPlaines Avenue, and Harlem Avenue, as well as a 10-foot-wide strip of parallel CTA right-of-way for expressway improvements. The area of right-of-way required is the same for all four build alternatives and does not require any displacements or relocations. It is anticipated that all right-of-way acquisitions would be made by IDOT. A summary of the new right-of-way required for the project is shown in Table 3-15 and described by location along the Project Corridor below.

Table 3-15. New Right-of-Way Required for Reconstruction of the I-290 Expressway



Location	Purpose	Area (acres)	No. of Parcels
25th Avenue (Bellwood & Broadview)	Expressway and interchange ramp improvements	0.459	16
1st Avenue (Maywood)	Expressway and interchange ramp improvements	2.768	8
DesPlaines Avenue (Forest Park)	Cross-road sidewalk improvements	0.050	2
Circle Avenue (Forest Park)	Cross-road sidewalk improvements	0.031[22]	2
Harlem Avenue (Forest Park)	Cross-road sidewalk improvements	0.014	4
CTA Blue Line (10-foot strip)	Expressway and interchange ramp improvements	2.650	1
Total		5.972	33

[22] Includes use of Section 4(f) property (see Section 3.12)

25th Avenue

Approximately 0.459 acre of new right-of-way is required from 16 parcels at 25th Avenue for interchange and mainline expressway improvements (Figure 3-9). Along 25th Avenue, some additional right-of-way is required to accommodate revised north and south interchange approaches associated with the proposed SPUI design. Along the mainline, additional right-of-way is required along the south side of the expressway, west of 25th Avenue, to accommodate an envelope for a potential future transit facility in the median of the expressway and new direct ramp connections to 25th Avenue.

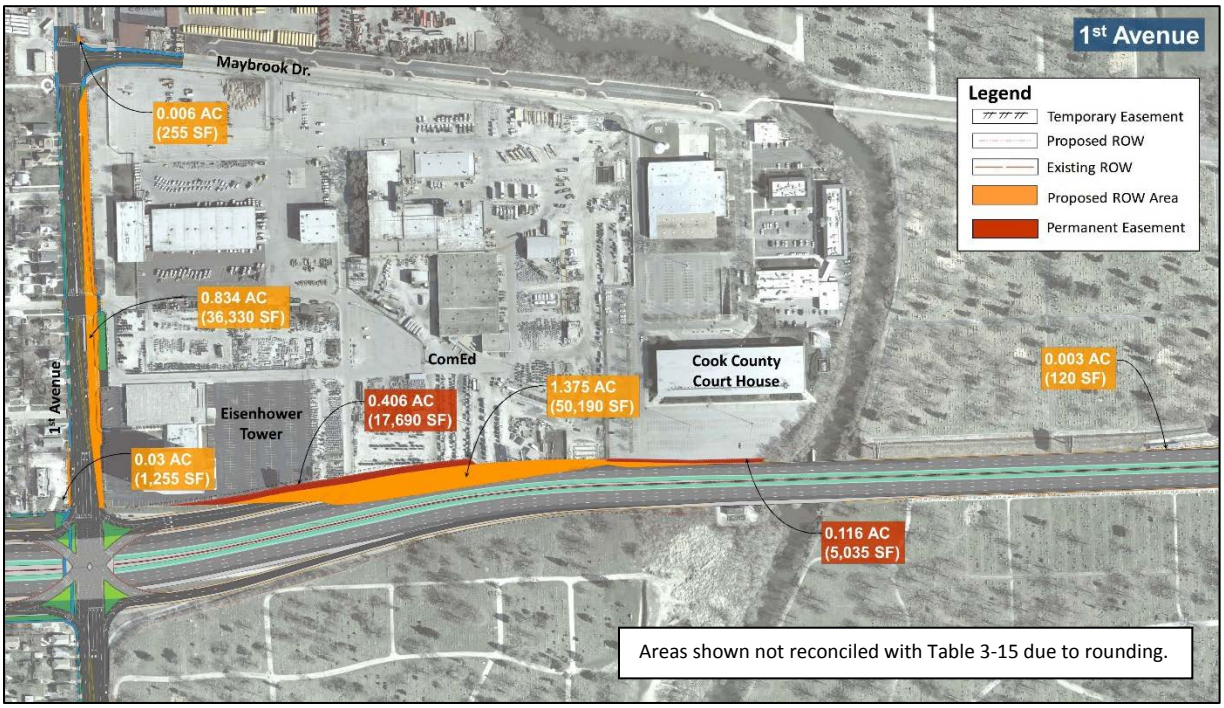


Figure 3-9. 25th Avenue Additional Right-of-Way Required

1st Avenue

A total of approximately 2.248 acres of right-of-way (ownership) and 0.522 acres of permanent easement are required from eight parcels for improvements to the 1st Avenue interchange approaches and mainline expressway improvements (Figure 3-10). Along 1st Avenue, improvements include dual left-turn lanes and improved channelization as part of the proposed SPUI design. Along the mainline of I-290, additional right-of-way is required to accommodate an envelope for a potential future transit facility in the median of the expressway and for improvements to the 1st Avenue ramps. As noted in Section 3.1.4.2, 27 parking spaces are impacted by the proposed improvement at the State of Illinois Circuit Court of Cook County Fourth Municipal District Maywood Courthouse.

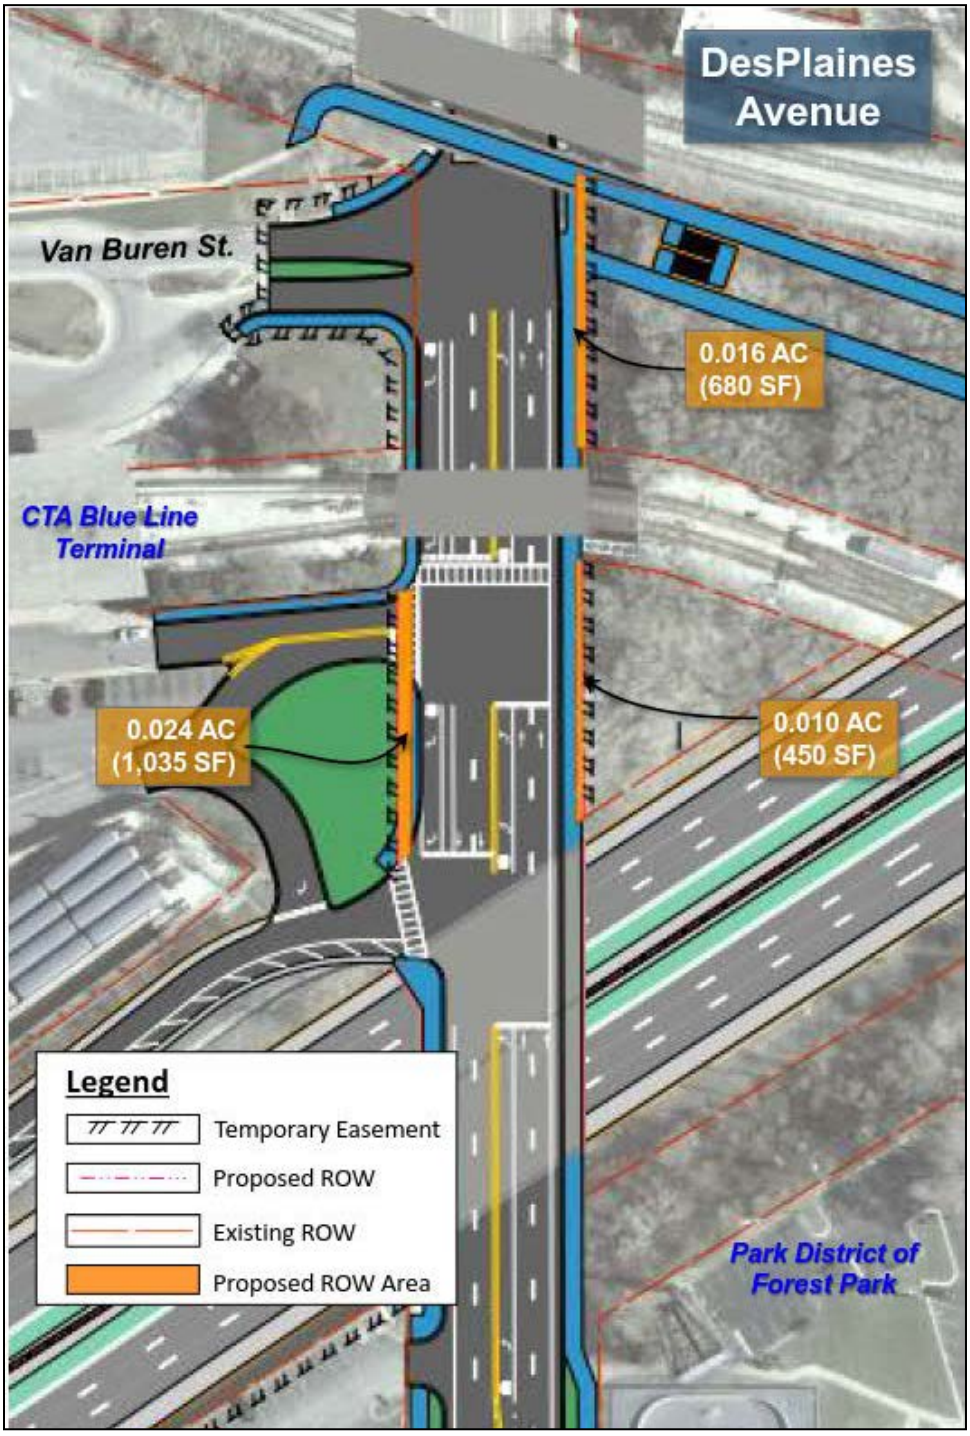

Figure 3-10. 1st Avenue Additional Right-of-Way Required

DesPlaines Avenue

Approximately 0.050 acre of new right-of-way is required from two parcels along DesPlaines Avenue associated with the proposed improvements to this street that include on-street bicycle lanes and sidewalk widening (Figure 3-11).

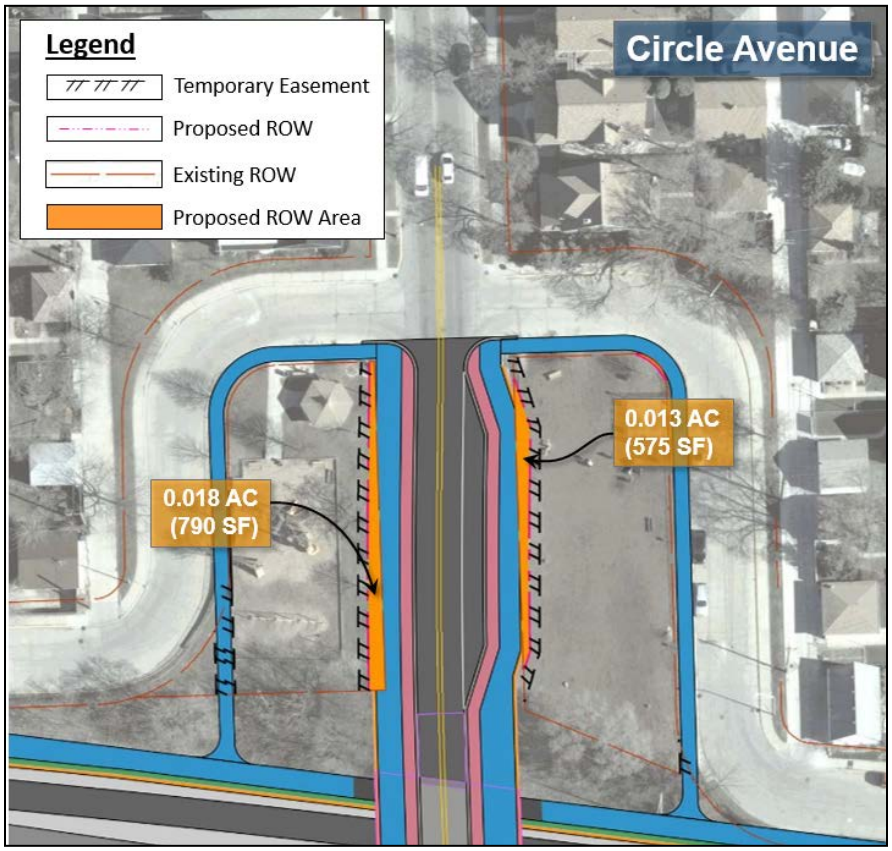

Figure 3-11. DesPlaines Avenue Additional Right-of-Way Required

Circle Avenue

Approximately 0.031 acre of new right-of-way is required from two parcels adjacent to Circle Avenue north of the expressway (Figure 3-12). The right-of-way required is associated with on-street bicycle lanes, sidewalk widening, and a vehicle turn out/CTA Blue Line kiss-and-ride waiting area. This right-of-way is also discussed in Section 3.12 as it is a Section 4(f) use of existing parkland.

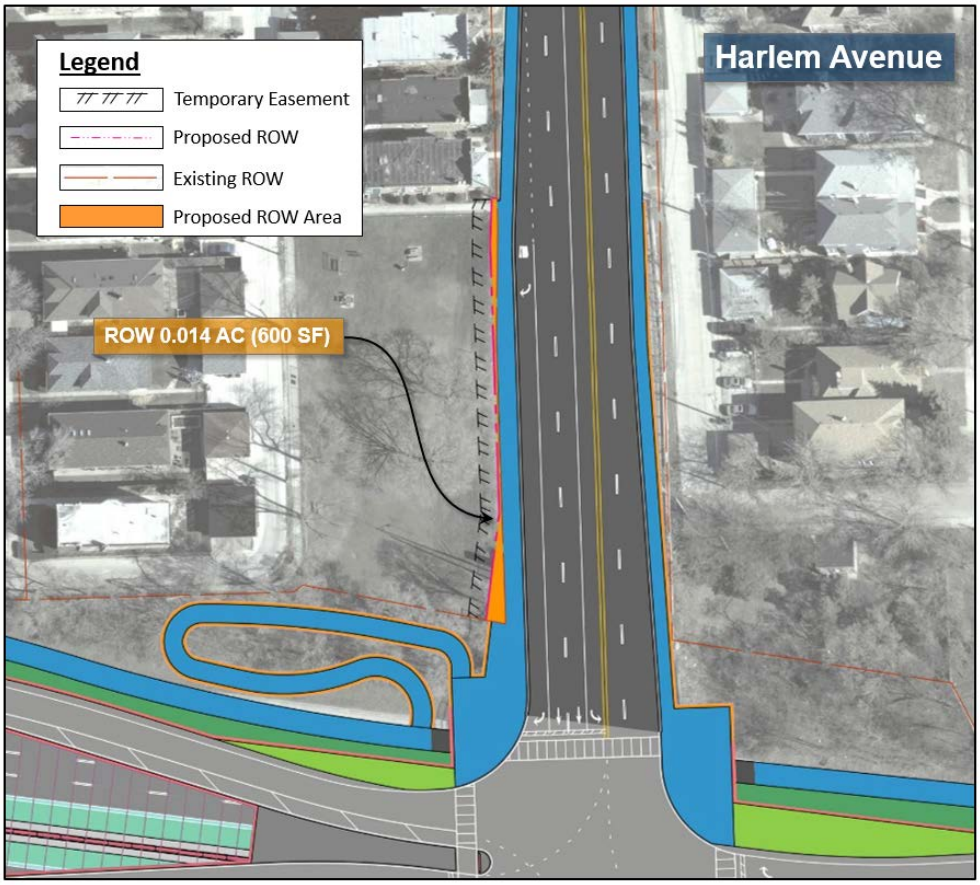

Figure 3-12. Circle Avenue Additional Right-of-Way Required

Harlem Avenue

An approximately 0.014 acre strip of new right-of-way is required from four parcels along the northwest quadrant of Harlem Avenue associated with the proposed sidewalk widening improvements (Figure 3-13).

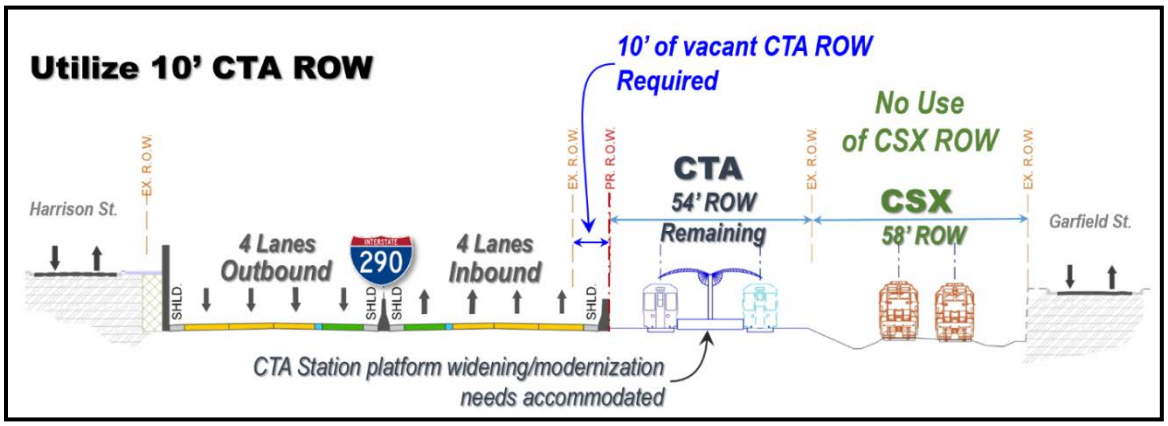

Figure 3-13. Harlem Avenue Additional Right-of-Way Required

CTA Right-of-Way

As part of the proposed project, a 10 foot-wide strip of existing vacant CTA Blue Line right-of-way would be utilized to accommodate expressway improvements, including wider shoulders and reconfigured ramps at Harlem Avenue and Austin Boulevard. The 2.65-acre strip of proposed right-of-way required from CTA comprises nearly half (44 percent) of the new right-of-way, extending approximately 11,700 feet (2.2 miles) along the north side of the CTA Blue Line generally from 700 feet west of Circle Avenue to 1,600 feet east of Austin Boulevard. The method of valuation and conveyance of right-of-way will be determined during Phase II Design. The remaining CTA right-of-way accommodates CTA's future track and station platform improvement needs. No right-of-way from CSX is required (Figure 3-14).

Figure 3-14. CTA Additional Right-of-Way Required

3.1.7.2 Mitigation of Impacts to Relocations and Right-of-way

The Uniform Relocation Assistance and Real Property Acquisition Act of 1970 (Uniform Relocation Act) [Title 42 US Code (USC) Sections 4601-4655], as amended, applies to all federal or federally assisted activities that involve the acquisition of real property or the relocation of residences or businesses. Just compensation would be provided for any property acquired for project right-of-way. Just compensation is monetary payment most often equivalent to the "fair market" value of the property. Fair market value is the highest price estimated in terms of money that the property would bring. The fair market value is based on exposure to sale on the open market, a reasonable time allowed to find a buyer, the knowledge of all of the uses to which it is adapted, and uses for which the property is capable. Mitigation of relocation impacts or displaced structures would be in the form of financial remuneration or compensation for property loss and relocation expenses, as outlined in the Uniform Relocation Act.

In summary, areas of the Project Corridor where new right-of-way may be required have been identified in and around the interchanges of I-290 with 25th Avenue, 1st Avenue, DesPlaines Avenue, Circle Avenue, and Harlem Avenue, along with a narrow strip of vacant CTA right-of-way. All necessary right-of-way acquisitions would conform to the Uniform Relocation Act, Real Property Acquisition Policies Act and the IDOT Land Acquisition Procedures Manual.

3.1.8 Transportation Network

3.1.8.1 Existing Conditions

The transportation network within the Study Area consists of local roads, highways, freight facilities, airports, heavy rail transit, intercity passenger bus, and nonmotorized (e.g., pedestrian, bicycle) facilities.

The Study Area roadway network includes facilities with different functional classifications to accommodate a variety of trip types in a manner consistent with historical travel patterns. The roadway functional classification system provides the

foundation for highway planning and the framework for determining the geometric design of individual roadways. Within a transportation system, the different functional classifications create a hierarchy of facilities designed to serve a range of travel demands from the local trip that is generally slower, shorter, and has higher accessibility to the longer trip, that is generally higher speed, longer distance, and with fewer access options.

The hierarchy of the functional classification systems for rural and urban areas generally consists of principal arterials, minor arterials, and collectors, followed by local roads and streets. The Project Corridor is completely within urban areas. The Project Corridor contains 35 miles of Interstate facilities and 26 miles of roads designated as principal or minor arterials; however, approximately 79 percent of roadways (293 miles) are local or municipal streets. The distribution of miles based on functional classification is shown in Table 3-16.

Table 3-16. Project Corridor Lane Miles by Functional Class and Direction

Functional Classification	Total Lane Miles	Percentage of Total
Interstate	35	12
Other Principal Arterial (Urban)	6	2
Minor Arterial (Urban)	20	7
Collector (Urban)	46	15
Local Road or Street (Urban)	193	64
Total	**300**	**100**

Other east-west roads in the Project Corridor are primarily local roads, collectors, or minor arterials.

Trucks

The Surface Transportation Assistance Act (STAA) of 1982 resulted in the designation of a national network of highways to allow the passage of trucks of specified minimum dimensions and weight. The objective was to promote uniformity throughout the nation for legal truck sizes and weights on a National Truck Network.

The network includes all Interstate highways, designated as Class I truck routes, and large portions of the federal-aid primary system (portions designated as Class II truck routes). Class I Highways are the Interstates and other four-lane, divided highways that are fully access controlled. Class II Highways are typically those routes with at least 11-foot-wide lanes and no history of abnormal accidents. Class I and II Highways can legally carry 80,000 pounds maximum gross weight and the wider 102-inch vehicle.

Within the Project Corridor, Class I truck routes include all of the Interstates, including I-290, I-294, I-88, and I-90/I-94. In general, the Class II truck routes include all or portions of the other US and state marked routes. Table 3-17 lists the Class I and II routes in the Project Corridor.

Table 3-17. Class I and Class II Truck Routes in Project Corridor

Route	Location	Class
I-88	Interstate 80 to Interstate 290 (Including Tollway)	I
I- 90	Wisconsin State Line to Indiana State Line (Including Tollway)	I
I- 94	Wisconsin State Line to Indiana State Line (Including Tollway)	I
I-290	Interstate 90 (Tollway) to Interstate 94	I
Illinois Route 43	US Route 30 to Illinois Route 60	II
Illinois Route 50	Manhattan/Monee Road to Illinois Route 19	II
US Route 12	Wisconsin State Line to Interstate 290	II

Source: Illinois Department of Transportation.

Class III truck routes are typically two-lane highways. This class can also carry the 80,000-pound load, but the vehicle width is restricted to a maximum of 96 inches, the same as allowed on most state and local designated truck route systems. There are no Class III truck routes in the Study Area.

Public Transportation (Transit)

Public transportation in the Project Corridor is provided by CTA, and Metra and Pace, which are operating divisions of the Regional Transportation Authority (RTA).

CTA

CTA provides HRT and bus service to the City of Chicago and 35 nearby suburbs, carrying more than 1.6 million riders on an average weekday. The CTA Blue Line Forest Park Branch provides 24-hour rapid transit train service between downtown Chicago and the Forest Park terminal station along the I-290 right-of-way. Service on the Forest Park Branch began operations as the Congress Branch of CTA's West-Northwest Route in June 1958.

The Congress Branch opened with stations on approximate 1-mile spacing. Connections to CTA and suburban bus routes (now PACE bus routes) have been a feature of these stations since their opening. An additional station was added to the line after it opened, and the west end of the line was relocated adjacent and to the south of the expressway right-of-way in 1959 and 1960. The two stations at either end of the Study Area, Clinton/Congress and DesPlaines Avenue (now Forest Park) terminal stations, are not located in the expressway median. The Clinton/Congress Station is a subway station located east of the end of the expressway. In the case of the Forest Park terminal,

sufficient land was required to provide bus interchange facilities, park-and-ride lots, a storage yard, repair shop, and the rapid transit terminal facilities. Three of the 15 stations (California, Kostner, and Central) on the branch were closed approximately 40 years ago as ridership declined. Current ridership on the Forest Park Branch is 33,000 average weekday riders, resulting in 60 percent utilization of its capacity.

Blue Line Forest Park Branch Feasibility/Vision Study

CTA conducted the *Blue Line Forest Park Branch Feasibility/Vision Study* concurrently with the I-290 EIS. The CTA Forest Park Branch originally began service in late June 1958. Many of the current infrastructure assets are original, while other facilities have undergone interim repair or replacement but are overdue for replacement. Over time, maintenance has been conducted to sustain safe operations. This approach has not been able to sustain the level of service (LOS) intended for the route, resulting in aged infrastructure, slow zones, and an overall reduced quality of service for customers. To provide a quality, efficient service for customers, there is a need for near total replacement and modernization of assets for the Blue Line Forest Park Branch.

CTA recommends that the entire Forest Park Branch be reconstructed in its entirety, similar to the programs that have addressed similar needs on the Red Line Dan Ryan Branch. Key recommendations include:

- Maintain existing entrance locations;
- Remove stations closed in 1970s;
- Improve infrastructure to a state of good repair;
- No third track or express service
- Improve the terminal site at Forest Park;
- Maintain existing service; and
- Work with IDOT on Project Corridor improvements through design, construction, and funding.

In the short term, CTA would continue to perform interim slow zone and other maintenance work.

Given the scope and extent of upgrades needed along the Forest Park Branch, CTA plans to continue evaluating funding options and project phasing in conjunction with their larger mission of modernization and bringing the transit system to a state of good repair.

Blue Line Extension

An extension of the Blue Line Forest Park Branch was introduced early in the I-290 Study by stakeholders and received strong support for testing as an initial alternative in Round 1. As described in Section 2.3.3.1, a 3.5-mile-long extension of the Forest Park Branch from its existing terminus west to a new terminal station near Mannheim Road was the most cost-effective extension. Most (54 percent) of the new ridership is estimated to consist of diversions from existing CTA, Metra, and Pace services, and more critically, current land

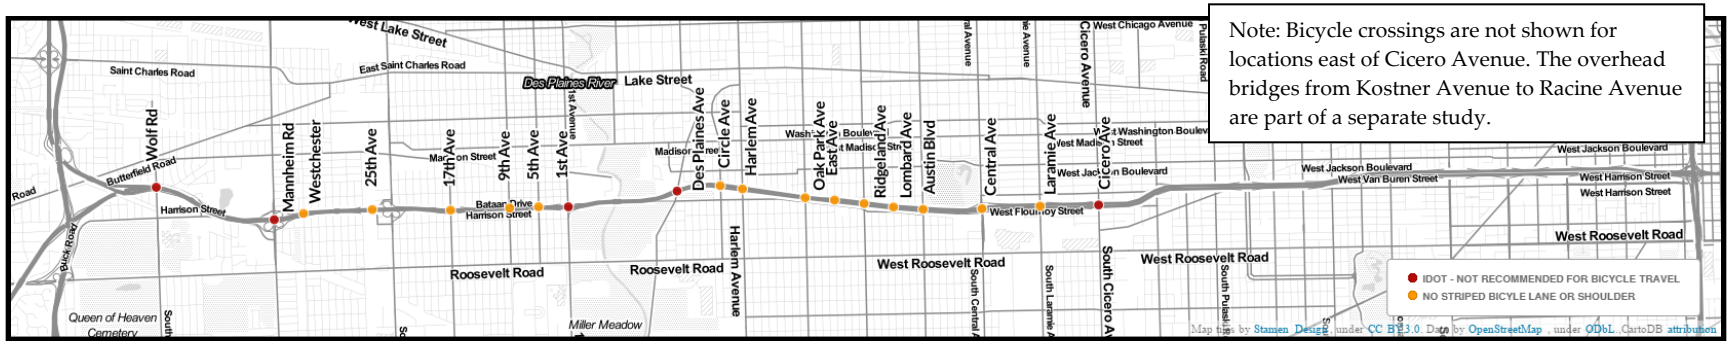
uses along a Blue Line extension do not generate forecasted ridership to support an HRT extension. As described above, CTA's current focus is on their backlog of bringing the existing HRT system to a state of good repair, as well as other capacity enhancement priorities. CTA acknowledged that future land use changes would be needed along the extension before the agency can support this major capital investment. For these reasons, CTA is not currently pursuing an extension of the Blue Line.

As part of this I-290 Study, IDOT has committed to a multimodal approach to alternatives development and, as part of this approach, all DEIS build alternatives include reserving space within the existing right-of-way from east of Forest Park to Mannheim Road as a potential future transit corridor either as an extension of the Blue Line or other fixed guideway transit extension. Express bus service could be provided as an initial transit extension service concept in this section, operating on the proposed shoulder or in a managed lane prior to any future heavy rail transit extension. Figure 2-28 depicts the convertible expressway section with the ultimate configuration accommodating the proposed Blue Line extension. The Blue Line Forest Park Branch west extension is listed as an unconstrained major capital project in the Chicago Metropolitan Agency for Planning (CMAP) *GO TO 2040 Comprehensive Regional Plan Update.*

Metra Commuter Rail

Metra operates 12 commuter rail lines that together currently carry more than 300,000 customers per day in the Chicago region.[23] Metra's Union Pacific West Line serves an area north and parallel to I-290, and it offers frequent service during traditional rush-hour patterns and less frequent service on off-peak weekday hours, holidays, and weekends.

Pace Bus Service



RTA's suburban bus division, Pace, provides fixed-route and express bus services between main boarding points, dial-a-ride, and paratransit service in less densely developed areas and for elderly and disabled patrons. Service is typically provided between 5:00 a.m. and 7:00 p.m. The weekend service varies by route.

Bicycle and Pedestrian Trails

There is limited pedestrian and bicycle access across the Project Corridor. Only two out of 21 existing crossings of I-290, Home and Lavergne avenues, are dedicated for pedestrian/bicycle use. Five major street crossings of I-290 (Wolf Road, Mannheim Road, 1st Avenue, DesPlaines Avenue, and Cicero Avenue) are designated 'Not Recommended for Bicycle Travel' by IDOT's Bicycle Map. The remainder of the streets crossing I-290 do not have shoulders or dedicated bicycle lanes that would provide safer, more comfortable operating zones for bicyclists. Figure 3-15 presents the existing bicycle crossings of I-290 in the Reconstruction Section of the Project Corridor, including those that are considered to be unsuitable.

[23] Metra. Operations and Ridership Data: July 2011 – June 2012. https://metrarail.com/about-metra/reports-documents/operations-ridership-data.

Figure 3-15. I-290 Bicycle Crossings – Reconstruction Section

In the Study Area communities, there are several shared-use trails, bicycle lanes, or designated bicycle routes that either cross or parallel I-290, as shown in Figure 3-16. Along with these existing bicycle and pedestrians facilities, there are also several planned future bicycle routes in the Project Corridor.

There are several dedicated bicycle lanes along existing roads within the Project Corridor in addition to existing and planned shared lane bicycle routes. Most of the dedicated bicycle lanes are located in the City of Chicago, including portions of Madison Street, Jackson Boulevard, Taylor Street, and Central Park Avenue. There are several dedicated lanes that cross I-290, including Clinton Street, Halsted Street, Ogden Avenue, and Central Park Avenue in Chicago, and DesPlaines Avenue and Circle Avenue in the Village of Forest Park. Also in Forest Park, dedicated bicycle lanes parallel I-290 along Lehmer Street and Harrison Street.

The Village of Forest Park has several bicycle lanes and bicycle routes/shared lanes. These routes cross I-290 at DesPlaines Avenue and Circle Avenue. The Village of Oak Park, Hillside, Westchester, and Broadview have no bicycle routes or shared lanes in the project area. Oak Park has marked shared lanes along Ridgeland Avenue and along the Ridgeland Avenue/I-290 overhead bridge. The City of Chicago has multiple existing and planned future bicycle routes crossing I-290.

The City of Chicago owns the Divvy bicycle sharing system, which allows users to make one-way trips using publicly available bikes. The bikes are locked into a network of docking stations and can be unlocked from one station and returned to any other station. There are currently 580 docking stations and 5,800 bikes located in Chicago, Oak Park, and Evanston with several stations located in the Project Corridor.

3.1.8.2 Impacts to Transportation

Traffic Changes

The four build alternatives all provide additional capacity in the form of an added lane in each direction on I-290 generally between east of Mannheim Road and Austin Boulevard. Table 3-18 presents forecasted 2040 average daily traffic (ADT) on I-290 for each of the build alternatives.

Table 3-18. Projected 2040 I-290 Average Daily Traffic (ADT)

I-290 Segment	No Build	GP Lane Alternative		HOV 2+ Alternative		HOT 3+ Alternative		HOT 3+ & TOLL Alternative	
	2040 Avg. Vol.	2040 Avg. Vol.	Δ from NB	2040 Avg. Vol.	Δ from NB	2040 Avg. Vol.	Δ from NB	2040 Avg. Vol.	Δ from NB
I-88 to 1st	182,000	215,000	18.1%	206,000	13.2%	210,000	15.4%	190,000	4.4%
1st to Central	200,000	234,000	17.0%	222,000	11.0%	225,000	12.5%	200,000	0.0%
Central to Sacramento	222,000	233,000	5.0%	220,000	-0.9%	224,000	0.9%	195,000	-12.2%
Sacramento to Racine	210,000	216,000	2.9%	204,000	-2.9%	208,000	-1.0%	175,000	-16.7%
Average	203,500	224,500	10.3%	213,000	4.7%	216,750	6.5%	190,000	-6.6%

Source: WSP Parsons Brinckerhoff, 2015.
Note: Numbers are rounded to 1 decimal point unless less than 0.05.

What is the difference between HOV Lanes and Managed Lanes?
HOV (High-Occupancy Vehicle) lanes are for vehicles with more than one occupant, and other exempt vehicles. Managed lanes can allow HOV use, but they also may accept single-occupant vehicles that pay a toll. Managed lanes that allow both HOV and tolled use are referred to as HOT (High-Occupancy Toll) lanes.

The GP Lane Alternative results in the highest increase in ADT on I-290 versus the No Build Alternative, with 10.3 percent more traffic. This is because the additional GP lane in each direction does not have any restrictions on who can use the lane (as opposed to a managed lane, which is restricted to HOVs and those paying tolls). The added GP lane carries more traffic, but it has the least improvement in I-290 travel time compared to the other three build alternatives with added managed lanes. This is because the additional capacity of the GP lane is unmanaged and, with strong demand, can result in saturated capacity conditions with unstable or forced stop-and-go traffic flow. As a result, on the western portion of I-290 between I-88 and Central Avenue, the GP lane has the highest projected increase in traffic (between 17 and 18.1 percent). This added traffic on the western portion results in an increase in through traffic on I-290 on the eastern portion between Central Avenue and Racine Avenue. This is caused by regional trips being drawn into the corridor due to the I-290 capacity improvements west of Austin Boulevard.

The HOV 2+ and HOT 3+ Alternatives average 4.7 percent and 6.5 percent more traffic, respectively, along I-290 than the No Build Alternative. This traffic growth is less than the traffic growth for the GP Lane Alternative, as the additional capacity and lane conversion is managed in the HOV 2+ and HOT 3+ Alternatives. With the added managed lane capacity in the western portion of I-290, there is between 11 and 13.2 percent increase in traffic for the HOV 2+ Alternative, and between 12.5 and 15.4 percent increase in traffic for the HOT 3+ Alternative. This traffic growth is less than

that of the GP Lane Alternative due to the use of the managed lane by only carpools, transit vehicles, and those vehicles paying tolls. The HOV 2+ and HOT 3+ Alternatives show a small decrease in traffic in the eastern portion of I-290 due to the conversion of a GP lane to an HOV or HOT lane. As described above, the managed lane would generally carry less traffic than a GP lane under congested conditions, but it would have faster travel times and more reliability. Increased reliability of the managed lanes is due to the high-occupancy and toll restrictions controlling the amount of traffic that enters into them, allowing traffic to flow at an approximate minimum 45 miles per hour (mph) during peak periods.

The HOT 3+ & TOLL Alternative is the only build alternative that results in a decrease in I-290 ADT compared to the No Build Alternative, with an overall average of 6.6 percent less traffic. This is due to the tolling of all lanes on I-290, resulting in traffic diversion from I-290 to the arterial system. The western portion of I-290 exhibits similar traffic levels to the No Build Alternative, even though there is an added lane in each direction. The eastern portion of I-290 shows between 12.2 and 16.7 percent less traffic as a result of the tolling of all lanes.

The I-290 improvements in the four build alternatives are also expected to result in changes to arterial traffic in the Study Area. Table 3-19 presents forecasted 2040 daily changes in VMT and VHT in the Study Area for the build alternatives relative to the No Build Alternative. This table shows that the HOT 3+ & TOLL Alternative, which tolls all lanes on I-290, is expected to attract more traffic and increase congestion on the Study Area arterial system, with higher VMT and VHT compared to the No Build Alternative, due to diverted traffic off of I-290 because of the tolling of all lanes. The GP Lane, HOT 3+, and HOV 2+ Alternatives are expected to improve Study Area arterial performance, because the added capacity on I-290 west of Austin Boulevard is expected to draw longer distance traffic from the arterial system. A more detailed discussion regarding differences in Study Area arterial performance among the build alternatives is presented below.

Table 3-19. Daily 2040 Study Area Arterial Travel Performance

Study Area Arterial Performance	2040 No Build	GP Lane	HOV 2+ Lane	HOT 3+ Lane	HOT 3+ & TOLL
Vehicle Miles of Travel	4,294,000	-24,600	+6,900	-8,900	+147,800
Vehicle Hours of Travel	255,300	-2,000	-1,000	-1,600	+6,800

Source: WSP Parsons Brinckerhoff, 2015.

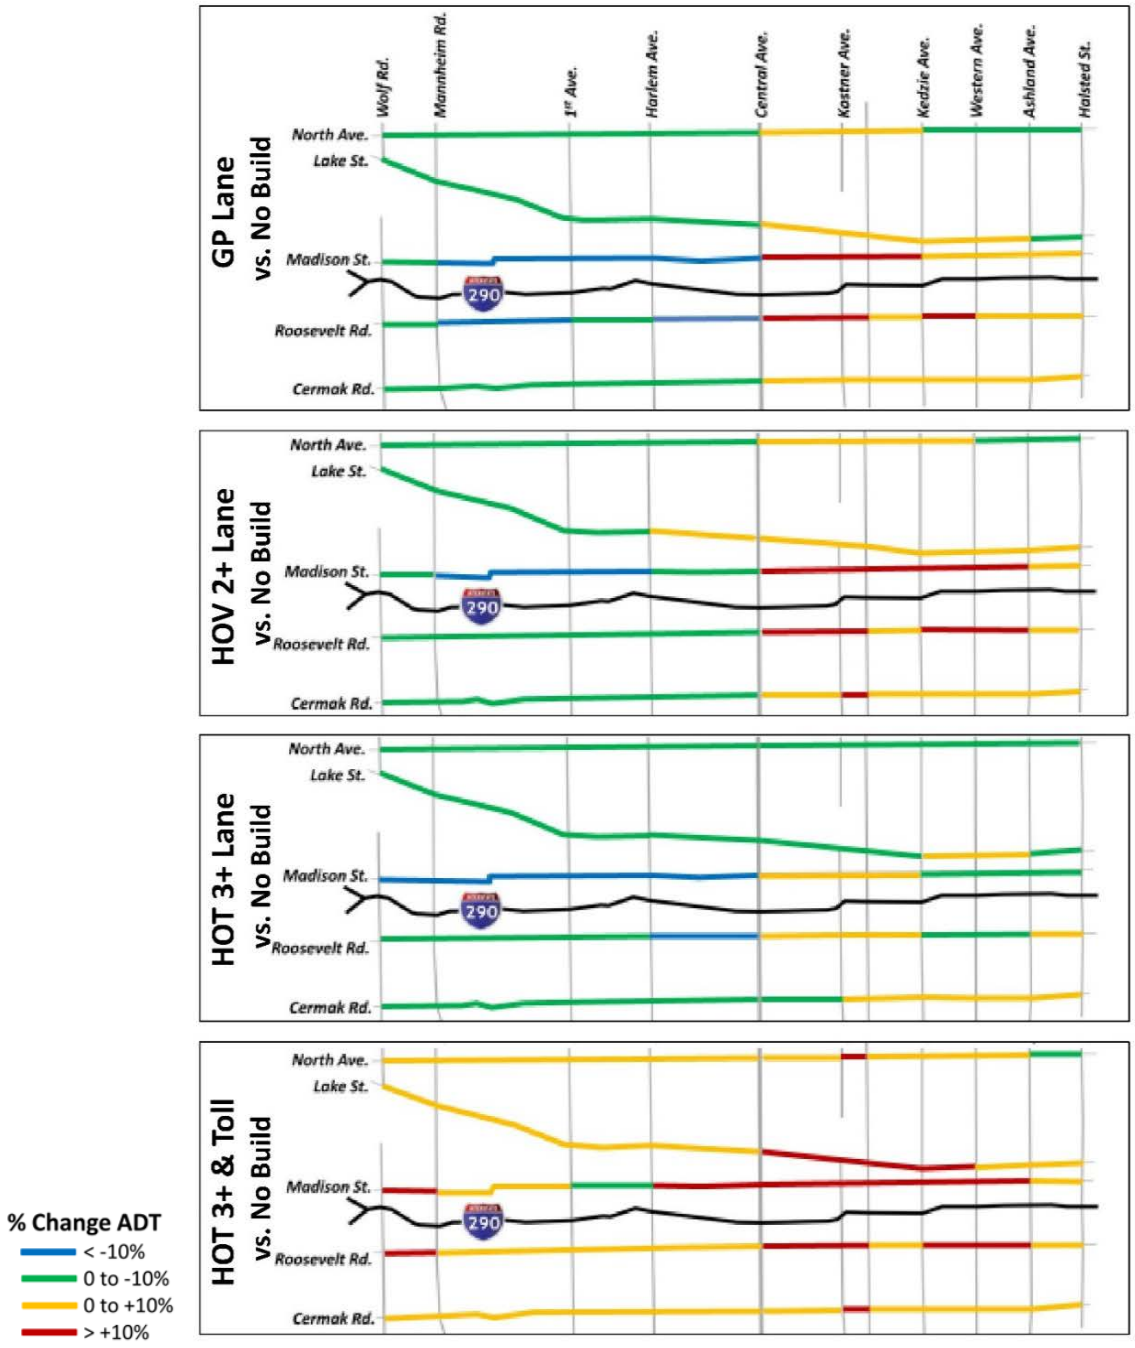
Figure 3-16 presents the forecasted change in 2040 ADT for the build alternatives on east-west arterials relative to the No Build Alternative. The following conclusions can be drawn from the information presented.

GP Lane Alternative:

- Traffic volumes are reduced on east-west arterials west of Central Avenue due to increased capacity of I-290 from the additional GP lane, drawing traffic off the arterials between Mannheim Road and Austin Boulevard.
- East-west arterial sections experience an increase in traffic east of Central Avenue from additional traffic being drawn to the I-290 corridor due to the increased mainline capacity west of Austin Boulevard.

HOV 2+ Alternative:

- Traffic is reduced on most east-west arterials west of Central Avenue due to increased mainline capacity from the HOV 2+ lane drawing traffic off the arterials between Mannheim Road and Austin Boulevard.
- East-west arterial sections experience an increase in traffic east of Central Avenue from additional traffic being drawn to the I-290 corridor due to the increased mainline capacity west of Austin Boulevard. Additionally, east of Central Avenue, the HOV 2+ lane conversion of the GP lanes result in a reduction to existing mainline capacity, resulting in greater diversion of I-290 traffic to the arterial routes in this section than with the GP Lane Alternative.



HOT 3+ Alternative:

- Traffic volumes are reduced on east-west arterials west of Central Avenue due to increased capacity provided by the HOT 3+ lanes on I-290 between Mannheim Road and Austin Boulevard. The HOT 3+ lanes perform better than the HOV 2+ lanes in that they provide more vehicle throughput than the HOV 2+ lanes.
- East of Central Avenue, the HOT 3+ Alternative also results in reductions to some east-west arterial traffic. This is due to an improvement in overall expressway throughput as a result of more efficient traffic management of the added HOT 3+ lane capacity west of Austin Boulevard in conjunction with the expressway lane conversion to HOT 3+ use to the east.

HOT 3+ & TOLL Alternative:

- Traffic volumes are increased on nearly all east-west arterials due to more longer-distance trips diverting from I-290 to avoid the tolls.

Figure 3-16. Projected 2040 East-West Arterial Volume Change for Alternatives versus No Build Alternative

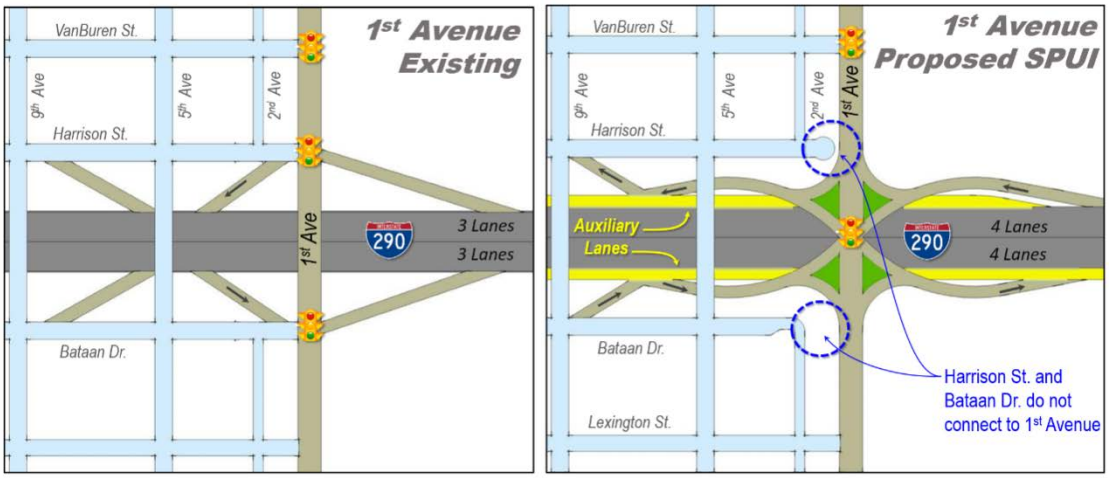
Overall, the forecasted change in 2040 east-west arterial ADT for each build alternative provides an indication of the benefit of moving traffic from the arterial roadways back to I-290. In some cases, this improved mobility attracts growth in population and jobs, which provide economic benefit, but can also bring new traffic demand. For example, east of Cicero Avenue, there is an increase in forecasted Study Area population of

1,502 people and 417 jobs in the build scenario, but also a corresponding slight increase in arterial traffic (Cicero Avenue is between Central and Kostner Avenues in Figure 3-17 below).

Roadway Network Modifications

Existing expressway access modifications within the Project Corridor, along with some supporting local roadway network changes, are limited to the 25th Avenue and 1st Avenue interchanges (Figure 3-17 and Figure 3-18). The proposed changes are common to all four build alternatives and are proposed to address existing design, operational, and safety deficiencies. The proposed changes occur in the communities of Westchester, Maywood, and Bellwood.

Figure 3-17. 1st Avenue Proposed Access Modifications



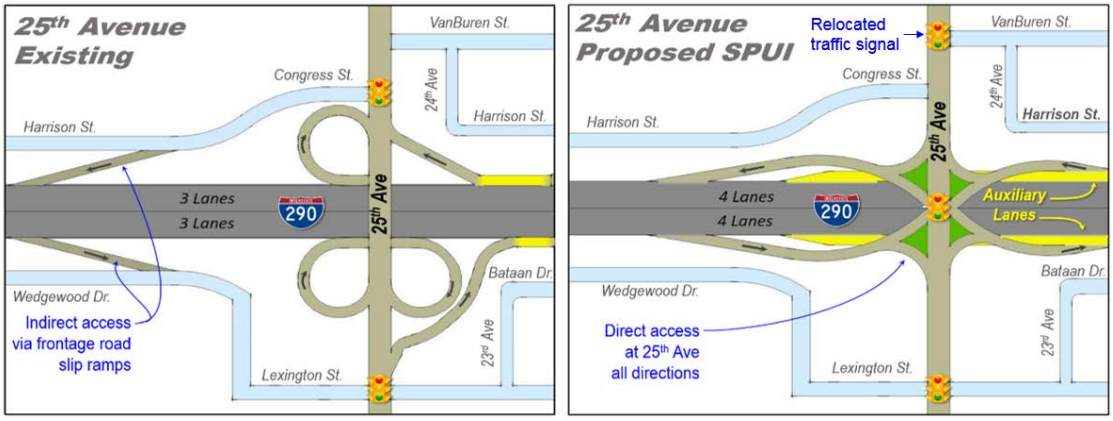


Figure 3-18. 25th Avenue Proposed Access Modifications

The access modifications at 25th Avenue include reconfiguring the existing indirect frontage road ramp connections as direct ramp connections at 25th Avenue. The proposed interchange is a SPUI, which accommodates expressway access to/from all directions directly at 25th Avenue.

The access modifications at 1st Avenue involve reconfiguring the existing tight diamond interchange and frontage road slip ramp type access as a SPUI with full directional access to/from the expressway at 1st Avenue. As part of the reconfiguration, the Harrison Street and Bataan Drive frontage roads would no longer connect to 1st Avenue. As part of the local Maywood outreach process, the frontage road connections were found not to serve as a primary local community access point. Disconnecting the frontage roads resulted in the greatest local benefit of improved operational efficiency of this very congested interchange, while discouraging expressway traffic using the local frontage roads as an expressway bypass.

Overall, these local network modifications and associated interchange reconfigurations result in a 23 percent improvement in local travel times to both economic and residential areas within the adjacent communities between 1st Avenue and 25th Avenue. Much of this improvement in local travel times can be attributed to the proposed geometric and operational improvements at 1st Avenue, which would reduce peak-period traffic queuing by as much as 77 percent and intersection delay by 74 percent, compared to the No Build condition.

Truck Traffic

The I-290 build alternatives all reduce truck hours of travel in the Study Area and have mixed results for truck miles of travel, as seen in Table 3-20.

Table 3-20. Projected Daily 2040 I-290 Study Area Truck Performance

Measure	No Build Alternative	GP Lane Alternative	HOV 2+ Alternative	HOT 3+ Alternative	HOT 3+ & TOLL Alternative
Truck Miles of Travel	1,215,700	+46,300	-7,900	+19,900	-116,600
Truck Hours of Travel	57,510	-150	-410	-240	-7,320

Source: WSP Parsons Brinckerhoff, 2015.

The GP Lane Alternative adds a GP lane in each direction on I-290 west of Austin Boulevard, resulting in increased truck capacity in this section. This results in increased truck travel on I-290 in 2040 ranging from 13,000 to 19,000 daily trucks compared to 12,000 to 16,000 daily trucks in the No Build Alternative. The increased number of trucks forecasted to use I-290 in the GP Lane Alternative results in an increase in truck miles of travel (+46,300); however, the I-290 travel times for the GP Lane Alternative are improved over the No Build Alternative by more than 9 minutes (Table 3-9), resulting in an overall decrease in truck hours of travel in the Study Area.

The HOV 2+ Alternative adds an HOV lane in each direction on I-290 west of Austin Boulevard; however, the added capacity provided by the HOV lane does not benefit trucks because they would be restricted from using the HOV lane. As a result, 2040 truck volumes on I-290 for the HOV 2+ Alternative are forecast to be 11,000 to 16,000 daily trucks, which is slightly less than the No Build truck volumes. Both truck miles of travel

and truck hours of travel for the HOV 2+ Alternative are expected to decrease in the Study Area, as I-290 travel times for the GP lanes are improved by more than 7 minutes (Table 3-9).

The HOT 3+ Alternative adds an HOT lane in each direction on I-290 west of Austin Boulevard; however, similar to the HOV 2+ Alternative, the added capacity provided by the HOT lane does not benefit trucks because they would be restricted from using the HOT lane. Forecasted 2040 truck volumes on I-290 are between 12,000 and 17,000 daily trucks, which is slightly higher than the No Build Alternative truck volumes. Those passenger cars using the HOT lane by paying a toll frees up a little more capacity in the GP lanes compared to the HOV 2+ Alternative, resulting in this small increase in trucks using I-290. This results in an increase in truck miles of travel in the Study Area but a decrease in truck hours of travel due to the decrease in I-290 travel times by more than 7 minutes (Table 3-9) compared to the No Build Alternative.

The HOT 3+ & TOLL Alternative adds an HOT lane in each direction on I-290 west of Austin Boulevard and tolls all of the GP lanes. The combined result of tolling all lanes and trucks not being able to use the HOT lane is a drop in the number of trucks using I-290. The HOT 3+ & TOLL Alternative is forecasted to carry between 5,000 and 10,000 trucks, which is a 40 to 60 percent decrease in trucks compared to the No Build Alternative. The HOT 3+ & TOLL Alternative is diverting trucks off of I-290 due to the tolling of all lanes, resulting in an overall reduction in truck miles of travel and truck hours of travel in the Study Area.

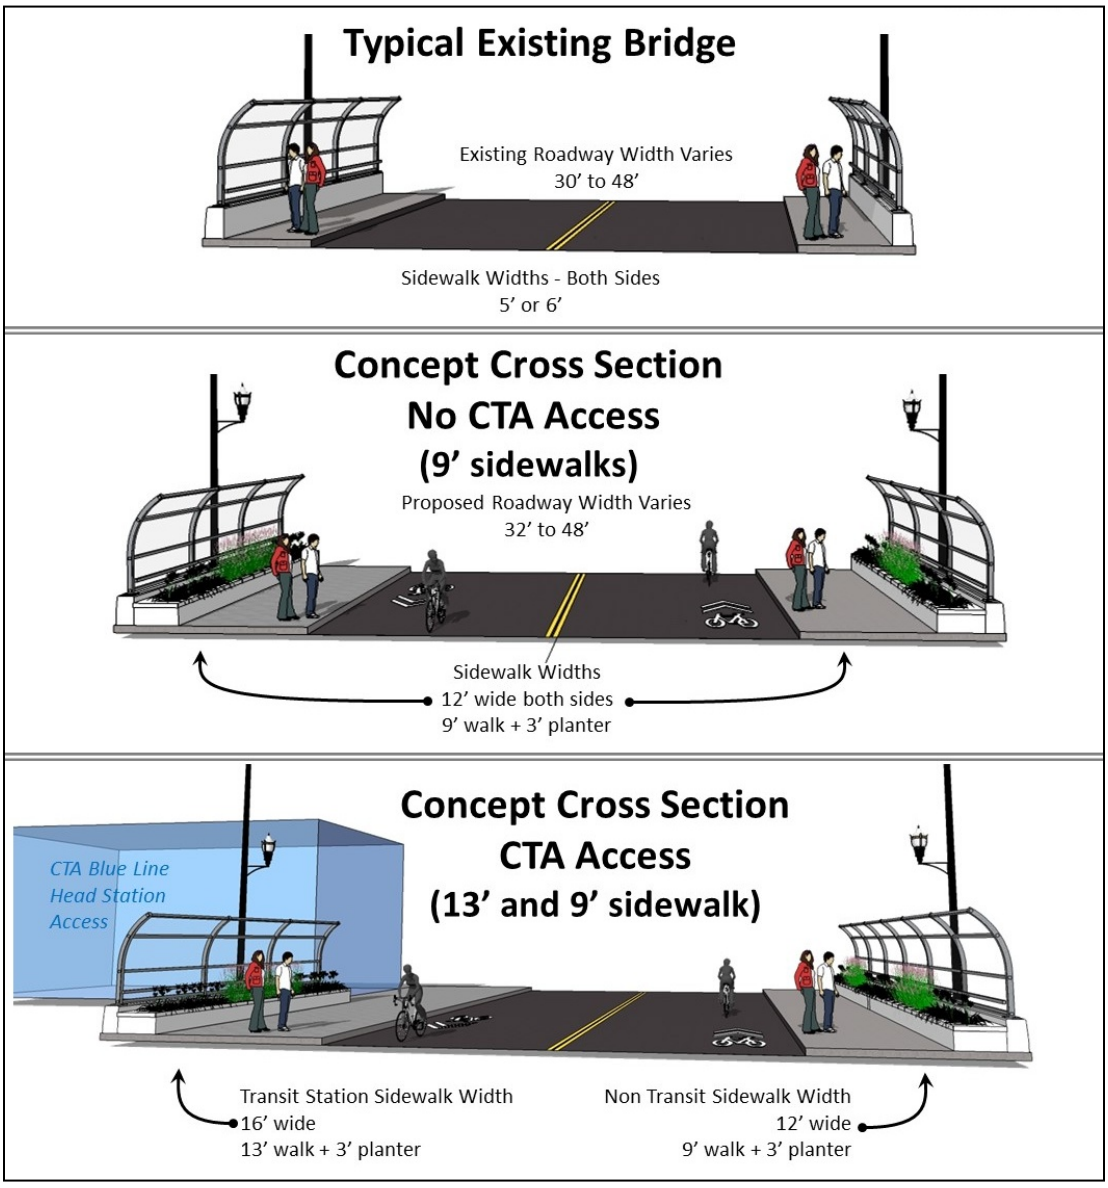
Pedestrian and Bicycle Facilities

All bicycle and pedestrian facilities proposed as part of the project have been coordinated with each local community in the corridor. Improvements to these nonmotorized facilities are primarily associated with the proposed improvements to the cross-roads and pedestrian bridges, as well as a new shared-use path paralleling I-290. All proposed bicycle and pedestrian facilities:

- Meet or exceed sidewalk width design standards;
- Accommodate current ADA standards;
- Include high-visibility, well-marked crossings; and
- Include updated signals with pedestrian countdown timers and/or signage.

Cross-Roads

Within the Reconstruction Section, the existing roads crossing I-290 are proposed to be reconstructed with bicycle and/or pedestrian improvements. These include:



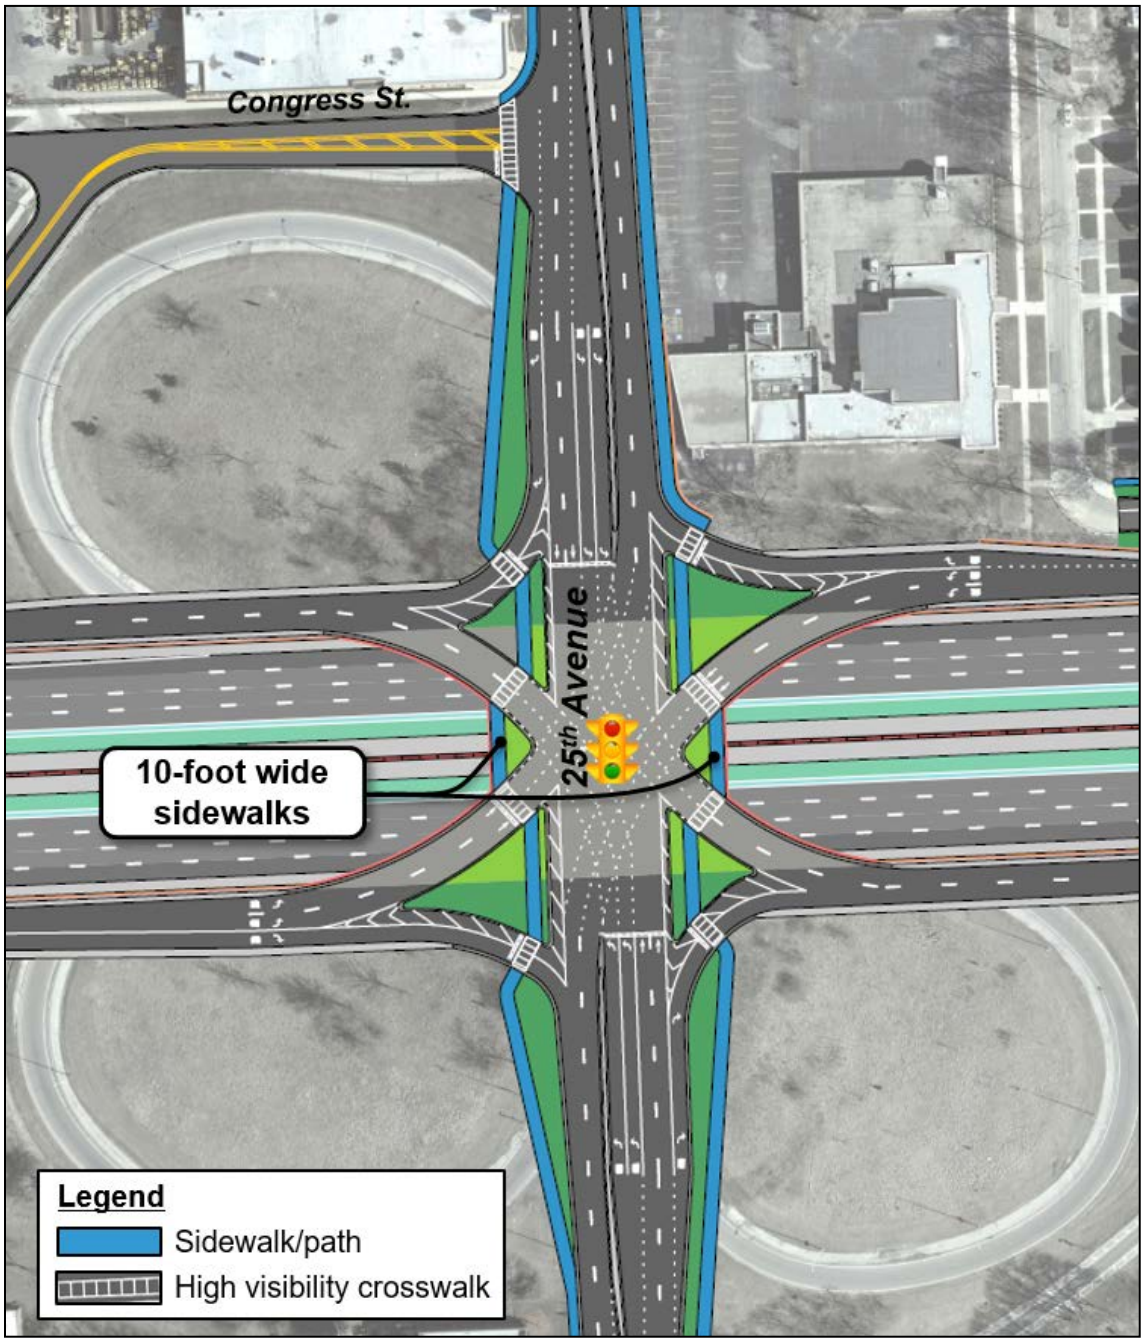
- 25th Avenue (US 12/45)
- 17th Avenue
- 9th Avenue
- 5th Avenue
- 1st Avenue (IL 171)
- DesPlaines Avenue
- Circle Avenue
- Harlem Avenue (IL 43)
- Oak Park Avenue
- East Avenue
- Ridgeland Avenue
- Lombard Avenue
- Austin Boulevard
- Central Avenue
- Laramie Avenue
- Cicero Avenue (IL 50)

Proposed bicycle and pedestrian improvements associated with each crossing were coordinated with the local municipalities, transit agencies, and stakeholders. Sidewalk widths and bicycle accommodations vary by location as determined through stakeholder coordination.

For more local cross-street bridges that were not part of a direct connection interchange with the expressway, a standard sidewalk typical section was developed and applied. This urban stitching approach to the local cross-street typical section was developed to improve north-south community connectivity, nonmotorized transportation and circulation across the expressway, improve transit connections, and accommodate hardscape and landscaping features that could be implemented by the local communities. This local cross-street typical section is illustrated in Figure 3-19 and was applied to the following local cross streets:

- 17th Avenue
- 9th Avenue
- 5th Avenue
- Oak Park Avenue (CTA Access)
- East Avenue (CTA Access)
- Ridgeland Avenue
- Lombard Avenue (CTA Access)

Figure 3-19. Local Cross-Street Bridge Typical Sidewalk Widths



From west to east, the following bicycle and pedestrian improvements are proposed along the roads crossing I-290 in the Reconstruction Section:

25th Avenue (US 12/45)

Along the east and west side of 25th Avenue, a 10-foot-wide sidewalk would be constructed over the expressway and through the proposed interchange (Figure 3-20). The 10-foot-wide sidewalks would transition back to 5-foot-wide sidewalks north and south of the interchange to minimize impacts and to tie back into existing sidewalks.

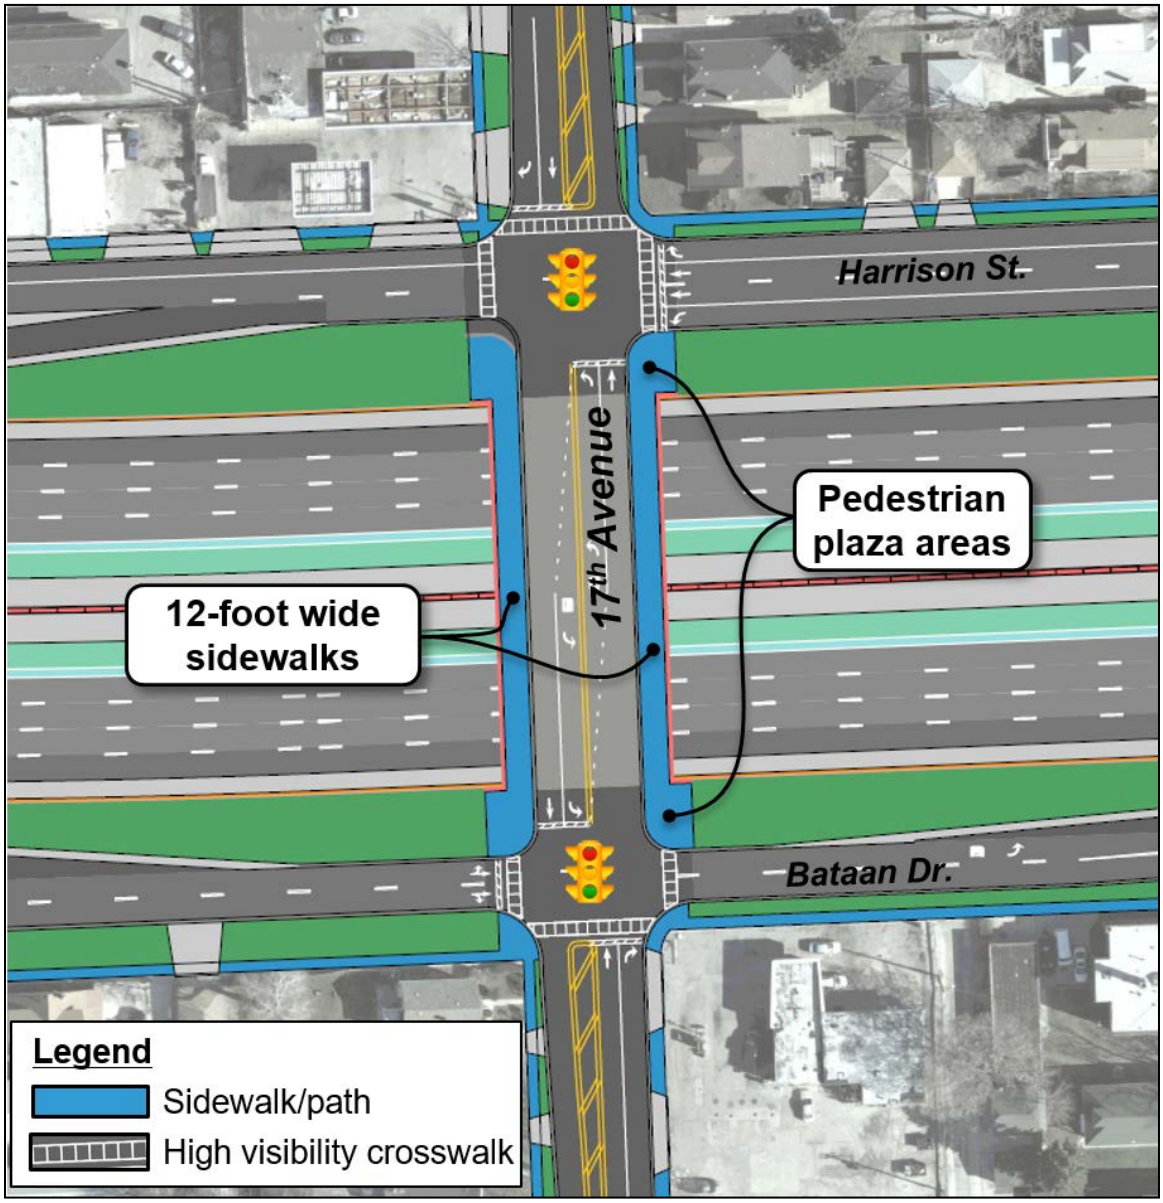


Figure 3-20. 25th Avenue Pedestrian and Bicycle Facility Improvements

17th Avenue

Twelve-foot-wide sidewalks would be provided along both sides of the proposed 17th Avenue bridge over I-290 between Harrison Street and Bataan Drive, which are signalized intersections (Figure 3-21). Wider sidewalks and pedestrian plaza areas are provided in each corner to provide additional area for pedestrian visibility and queuing, and also provide space for hardscape/street furniture/aesthetic features if implemented by the local community.

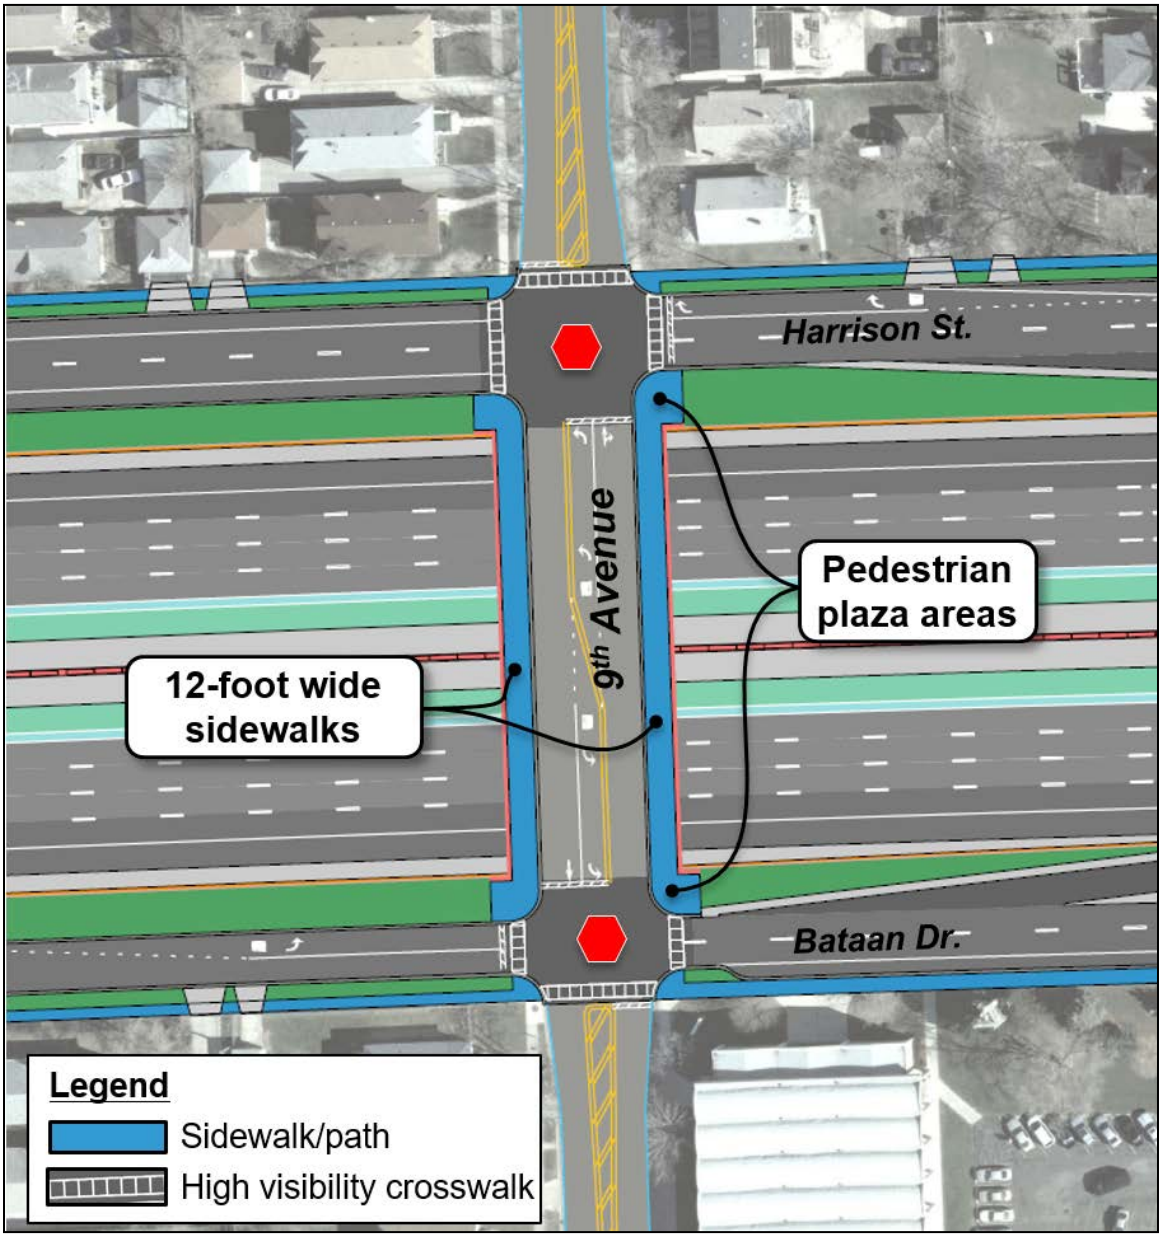

Figure 3-21. 17th Avenue Pedestrian Improvements

9th Avenue

Twelve-foot-wide sidewalks would be provided along both sides of the proposed 9th Avenue bridge over I-290 between Harrison Street and Bataan Drive, which are stop-controlled intersections (Figure 3-22). Wider sidewalks and pedestrian plaza areas are provided in each corner to provide additional area for pedestrian visibility and queuing, and also provide space for hardscape/street furniture/aesthetic features if implemented by the local community.

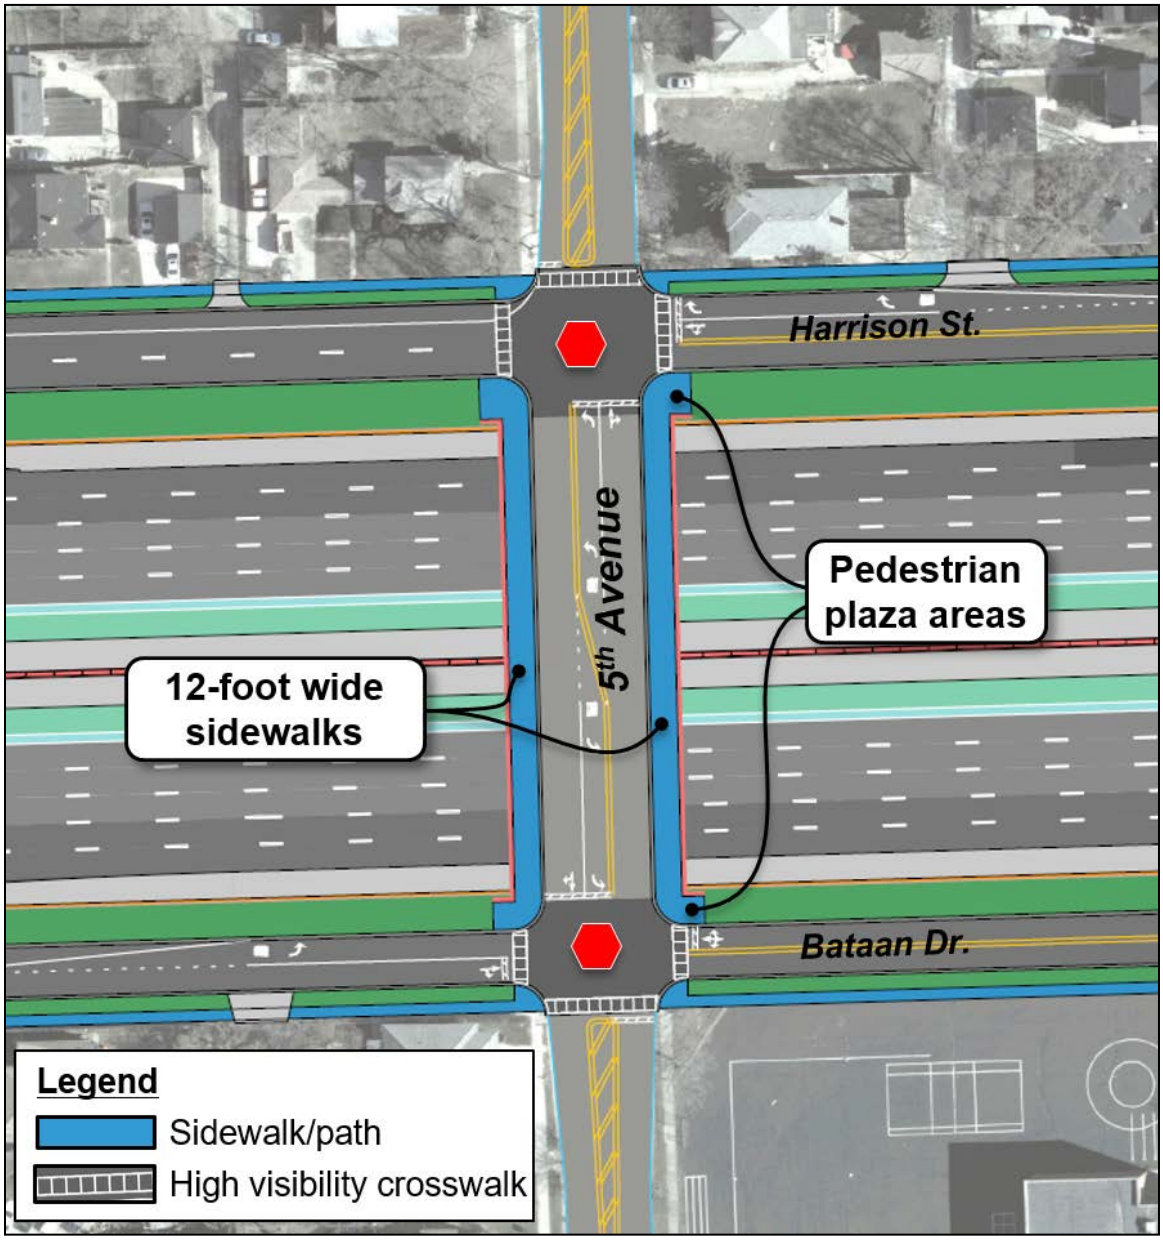

Figure 3-22. 9th Avenue Pedestrian Improvements

5th Avenue

Twelve-foot-wide sidewalks would be provided along both sides of the proposed 5th Avenue bridge over I-290 between Harrison Street and Bataan Drive, which are stop-controlled intersections (Figure 3-23). Wider sidewalks and pedestrian plaza areas are provided in each corner to provide additional area for pedestrian visibility and queuing, and also provide space for hardscape/street furniture/aesthetic features if implemented by the local community.

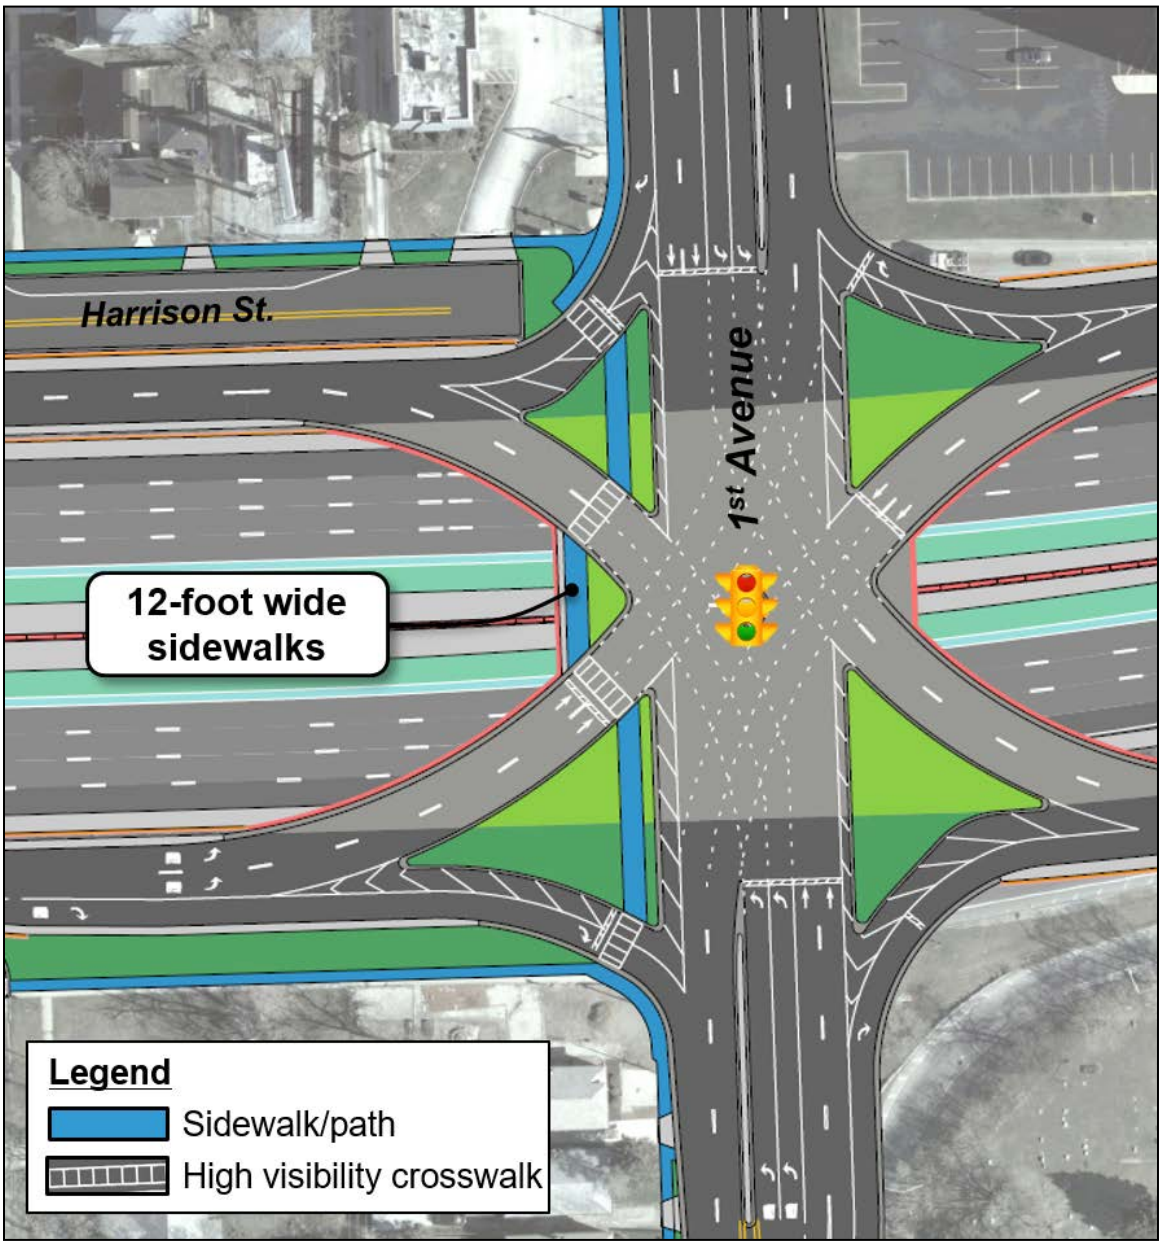

Figure 3-23. 5th Avenue Pedestrian Improvements

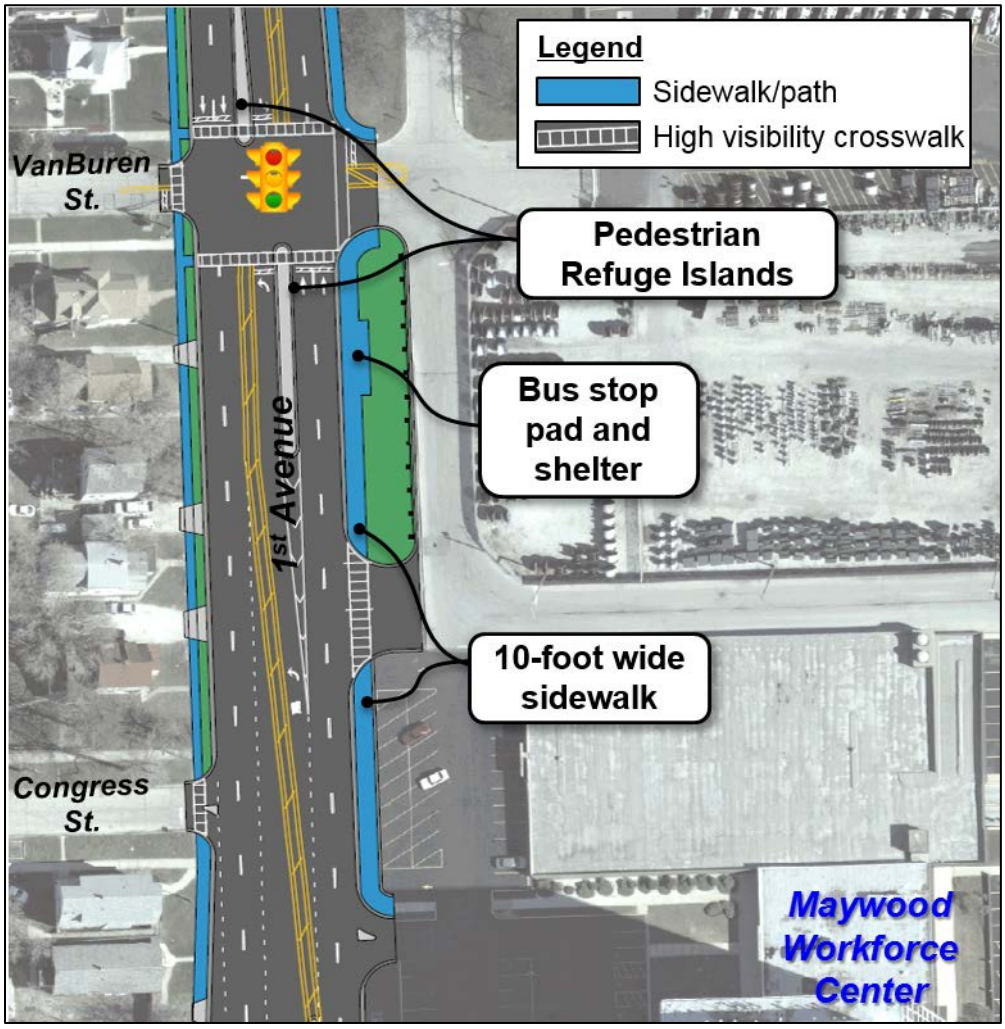
1st Avenue



Along the west side of 1st Avenue, a 10-foot-wide sidewalk/shared-use path would be constructed over the expressway and through the proposed interchange (Figure 3-24). The 10-foot-wide sidewalk would transition back to a 5-foot-wide sidewalk north and south of the interchange to minimize impacts and to tie back into existing sidewalks along 1st Avenue, Harrison Street, and Bataan Drive.

Figure 3-24. 1st Avenue Interchange Pedestrian Improvements

At 1st Avenue and Van Buren Street, a Pace Bus Route 320 shelter would be located in the southeast corner (Figure 3-25). This bus shelter would service the Maybrook Workforce Center, located in the Eisenhower Tower building to the south, via a 10-foot-wide sidewalk. Raised concrete pedestrian refuge islands would be located along 1st Avenue at the north and south approaches to the Van Buren Street intersection.

Figure 3-25. 1st Avenue and Van Buren Street Pedestrian Improvements

At 1st Avenue and Maybrook Drive, intersection improvements would add three new signalized bicycle and pedestrian crossings, including two east-west crossings of 1st Avenue and a north-south crossing of Maybrook Drive (Figure 3-26). These bicycle and pedestrian crossings would complete the missing connection of the Illinois Prairie Path to the existing Des Plaines River bicycle and pedestrian bridge crossing to the east, and provide connections to the CTA Blue Line Terminal and the proposed east-west shared-use path that would extend along I-290 between DesPlaines Avenue and Central Avenue.

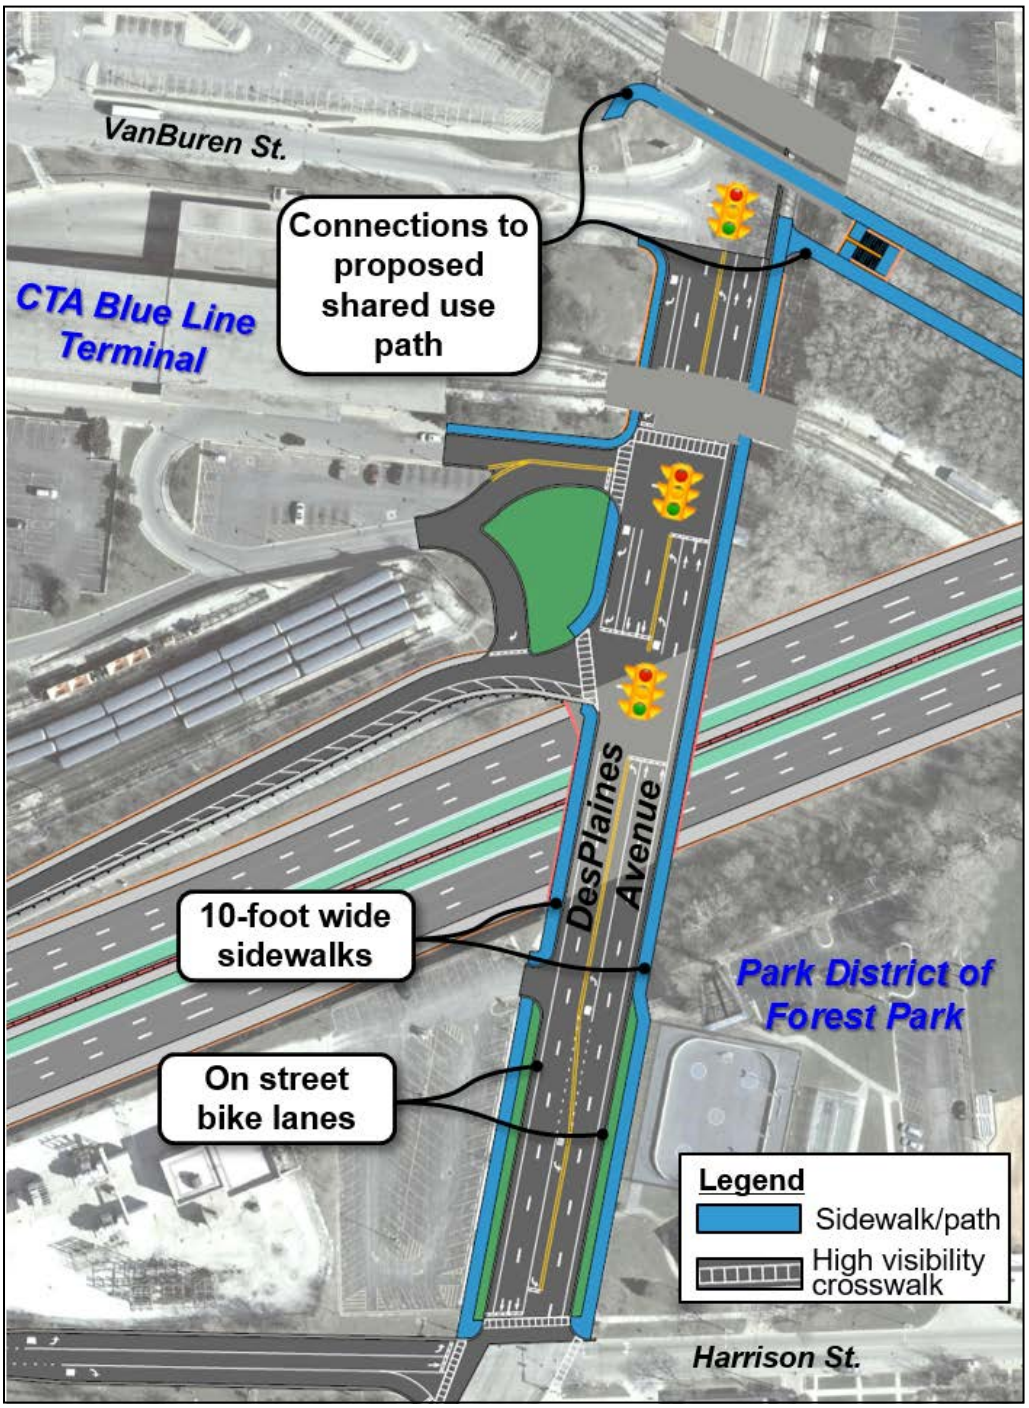


Figure 3-26. 1st Avenue and Maybrook Drive Bicycle and Pedestrian Improvements

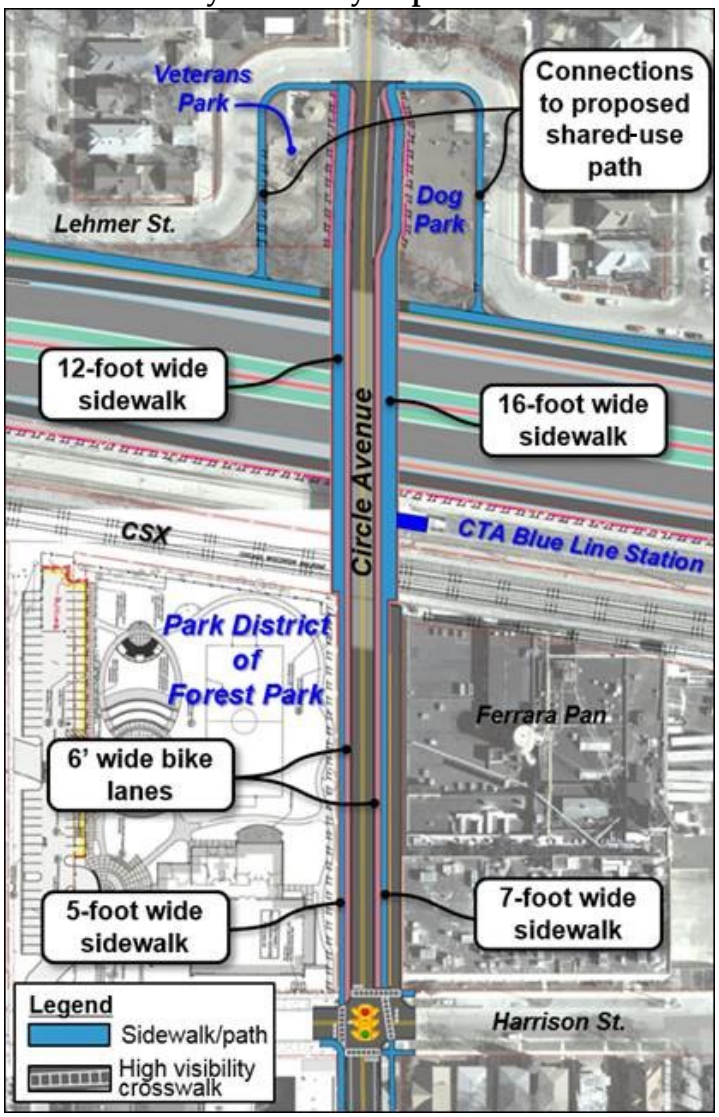
DesPlaines Avenue Interchange

Ten-foot-wide sidewalks and on-street bicycle lanes are proposed along both sides of DesPlaines Avenue between Harrison Street and Van Buren Street (Figure 3-27). Connections from DesPlaines Avenue to the proposed east-west shared-use path would also be provided via ramps and stairs. The shared-use path would cross over DesPlaines Avenue along to the south of the existing CSX railroad bridge.

Figure 3-27. DesPlaines Avenue Pedestrian and Bicycle Facility Improvements



Circle Avenue

Circle Avenue is designated by the Village of Forest Park as its primary north-south bicycle route and is the only crossing of I-290 not associated with an interchange. Circle Avenue connects between the Park District of Forest Park, located just south of I-290, and two pocket parks just north of the expressway (Veterans Park and a Dog Park). Also, a CTA Blue Line station entrance is located along the east side of the bridge.

A 12-foot-wide sidewalk is proposed along the entire west side of the bridge, and a 16-foot-wide sidewalk is proposed along the east side of the bride where the CTA Blue Line station access is located (Figure 3-28). Along the southeast side of the bridge, the sidewalk would narrow to 7 feet wide to maintain the existing alley access to the Ferrara Candy Company. The Village of Forest Park is also considering adding a marked pedestrian crossing of Circle Avenue near the CTA Blue Line station entrance.

Six-foot-wide dedicated and marked bicycle lanes are also accommodated along Circle Avenue in each direction between Harrison Street and Garfield. To provide some physical separation between the street traffic and the bicycle lanes, the bicycle lanes would be located behind the street curb and be at the same level as the sidewalk. The 6-foot bicycle lane widths would be in addition to the proposed sidewalk widths.

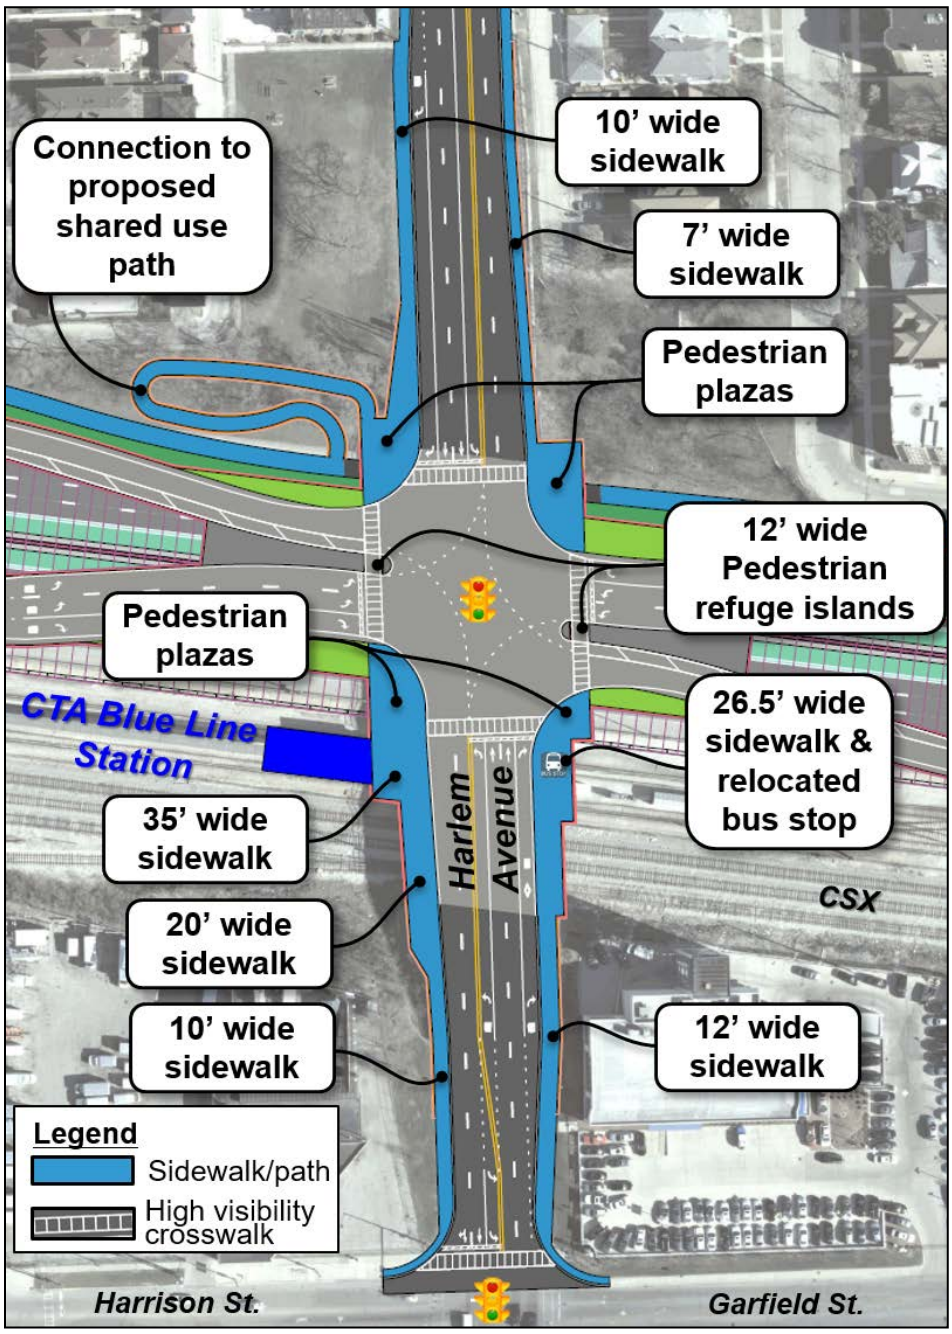


Figure 3-28. Circle Avenue Pedestrian and Bicycle Facility Improvements

Harlem Avenue

Approximately 15,200 square feet of additional sidewalk area is proposed along Harlem Avenue in connection with the proposed reconstruction of this interchange (Figure 3-29). Wider sidewalks, pedestrian plaza areas, and pedestrian refuge islands between the ramps are accommodated, as well as a bicycle and pedestrian connection to the proposed east-west shared-use path that passes underneath Harlem Avenue. Additional sidewalk width can also be utilized for hardscape/street furniture/aesthetic features if implemented by the local community.

Figure 3-29. Harlem Avenue Pedestrian and Bicycle Facility Improvements

Oak Park Avenue, East Avenue, Lombard Avenue, Ridgeland Avenue

Unless restricted by an existing right-of-way or other existing constraint, minimum 12-foot-wide sidewalks are proposed to be included in the baseline design (Figure 3-30 through Figure 3-33). If the sidewalk provides access to an existing Blue Line transit station, a 16-foot-wide sidewalk is proposed. At Oak Park Avenue, 16-foot-wide sidewalks are proposed along both sides of the street as this street serves to connect the Oak Park central business district (CBD). The 12- and 16-foot-wide sidewalks could also accommodate other aesthetic treatments such as locally funded and maintained hardscape or planter box features.

Figure 3-30. Oak Park Avenue Pedestrian and Bicycle Facility Improvements

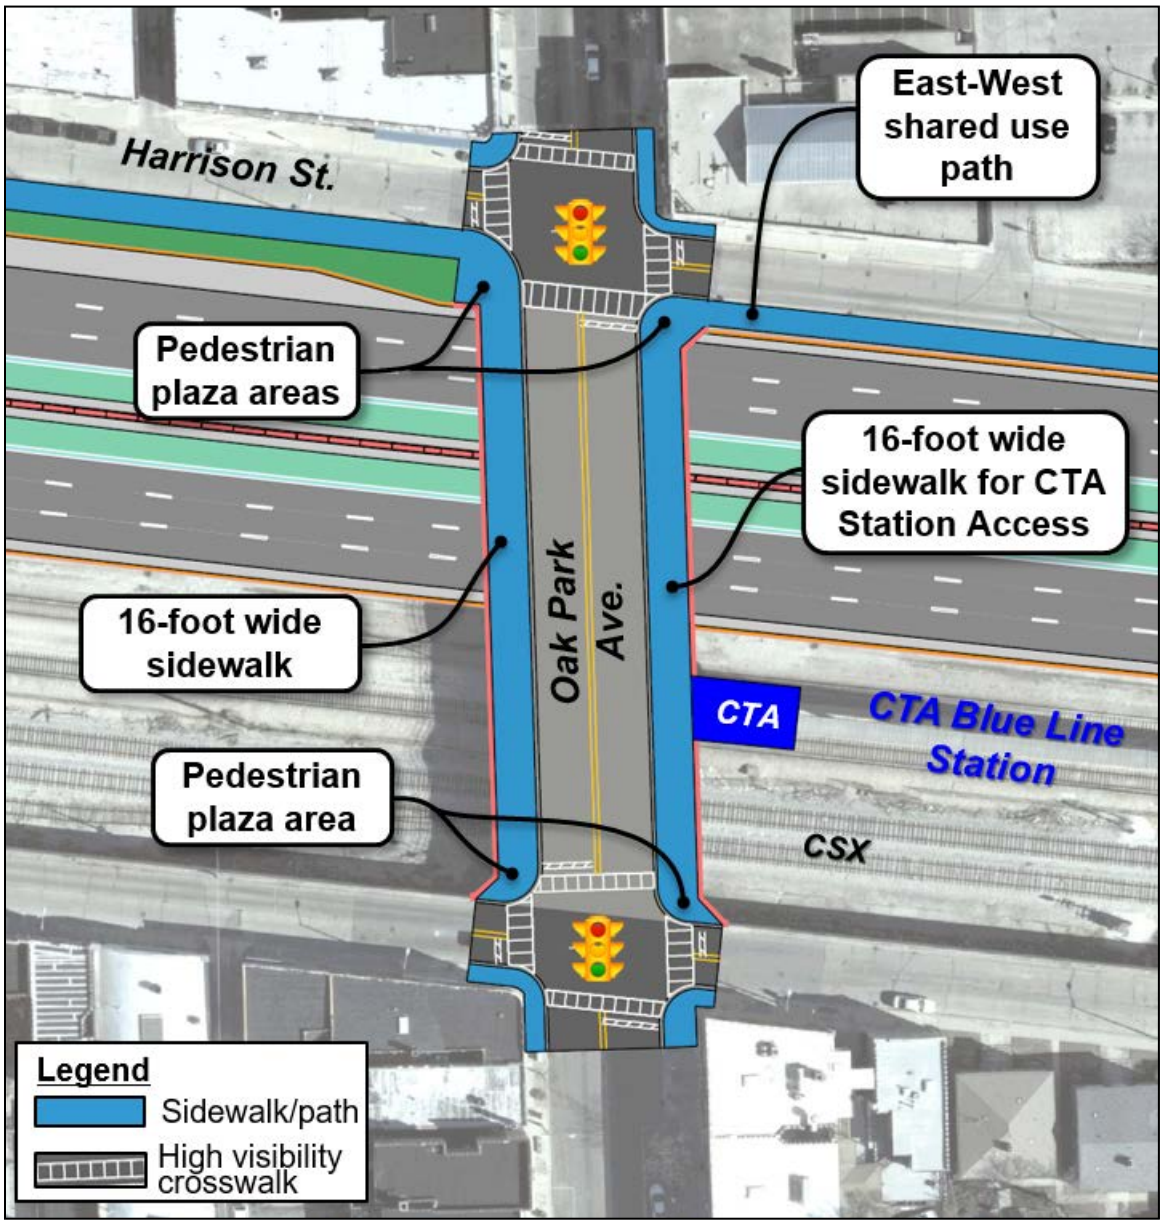

Figure 3-31. East Avenue Pedestrian and Bicycle Facility Improvements

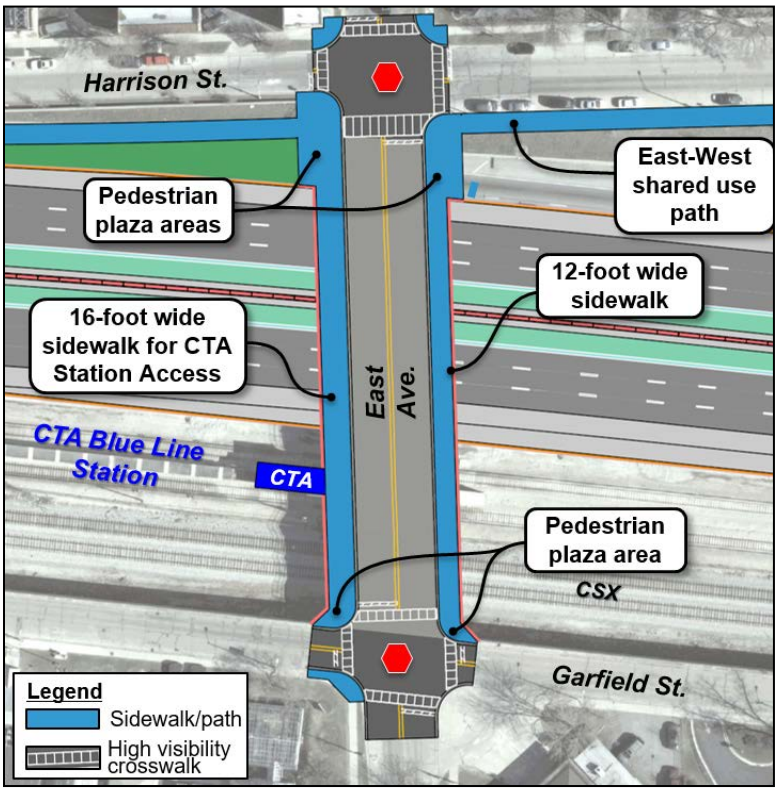

Figure 3-32. Ridgeland Avenue Pedestrian and Bicycle Facility Improvements

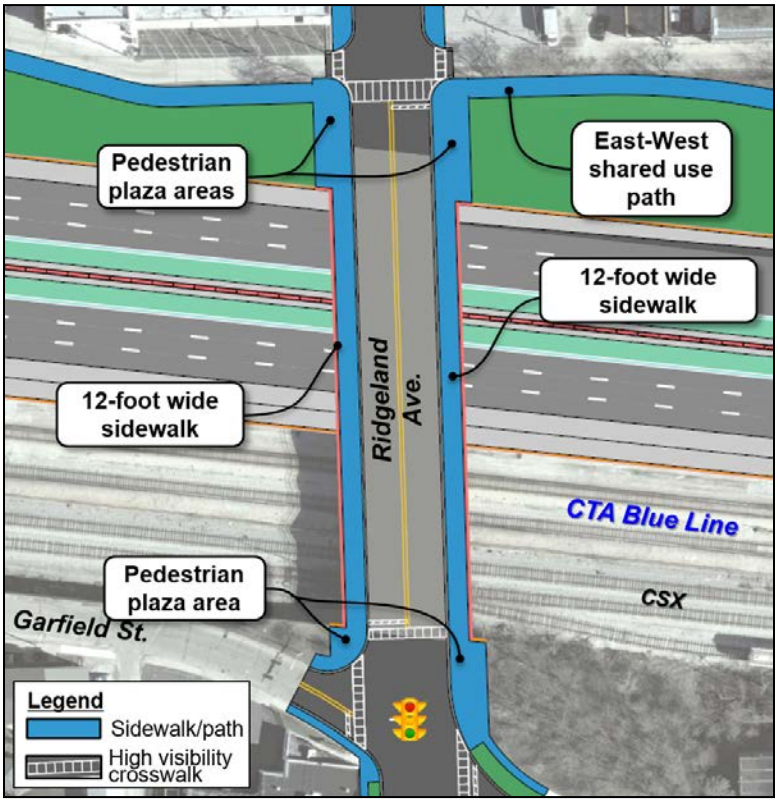

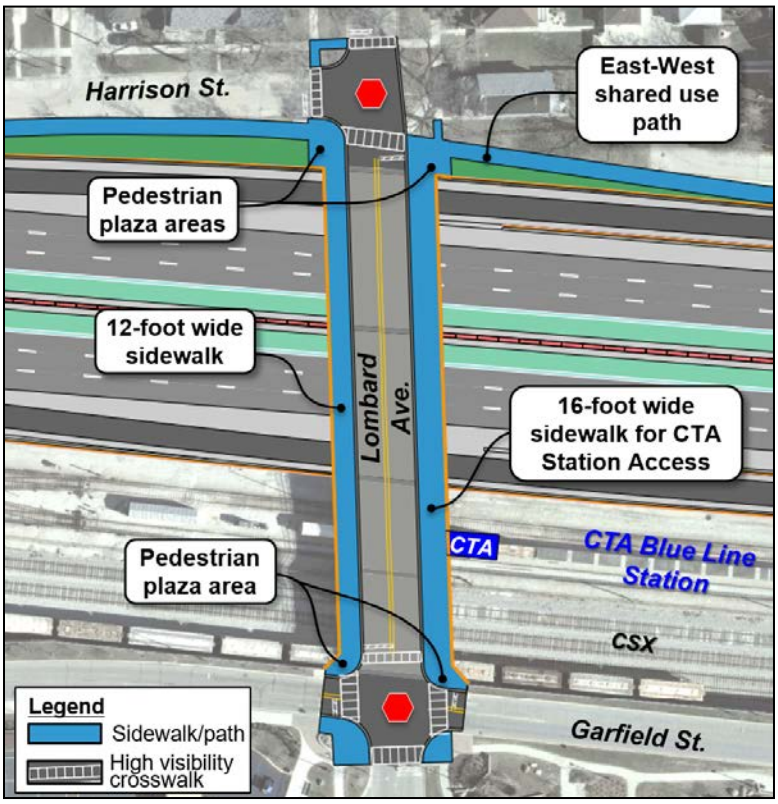

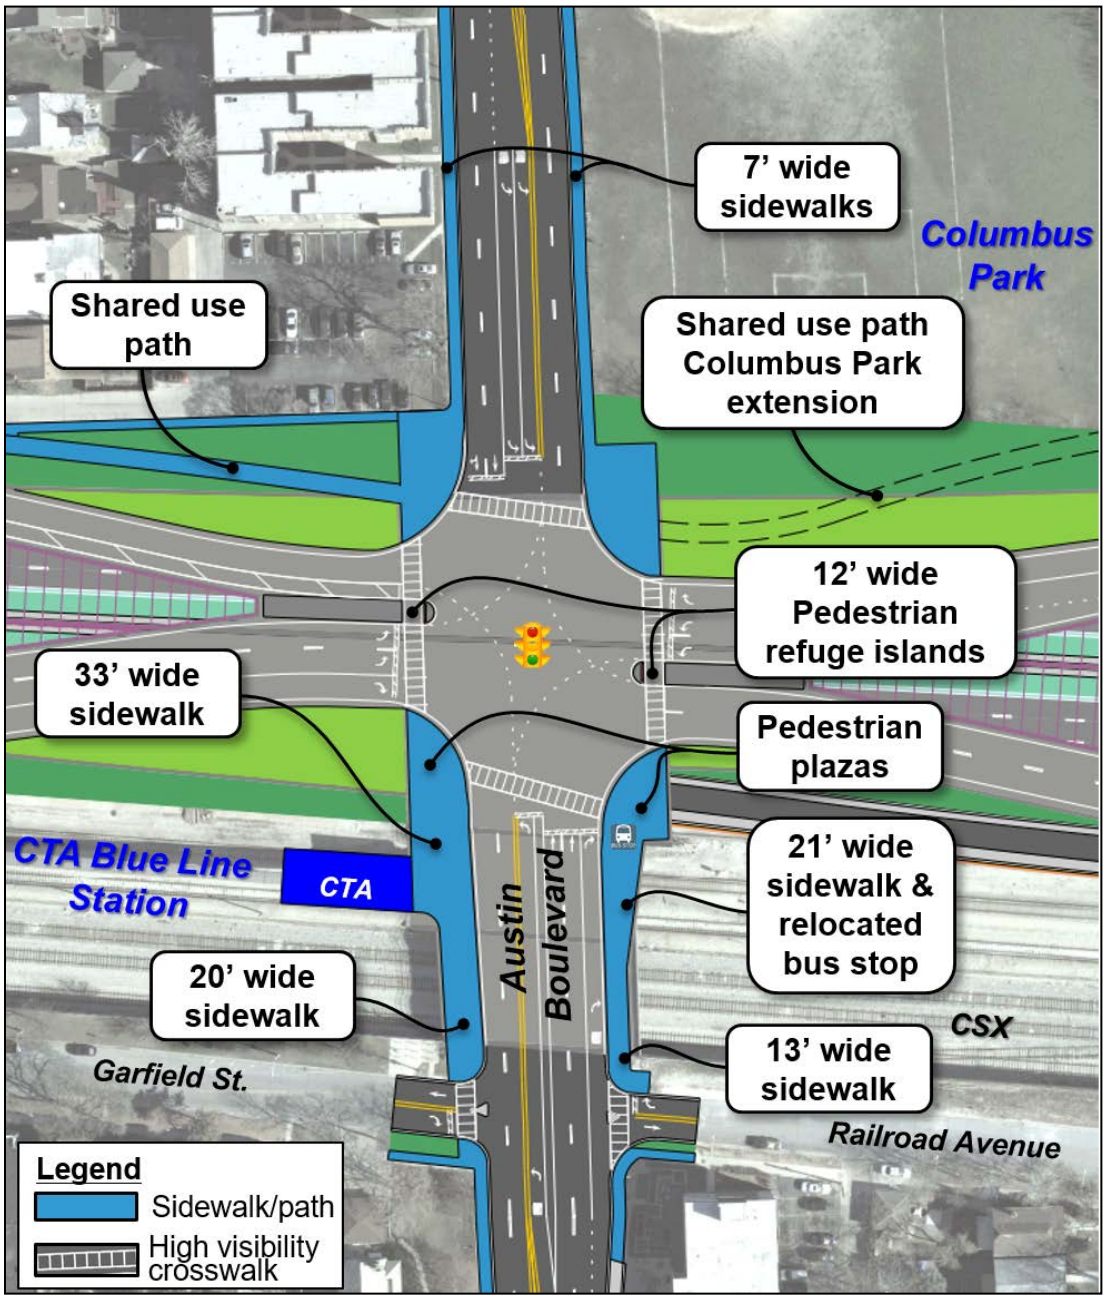

Figure 3-33. Lombard Avenue Pedestrian and Bicycle Facility Improvements

Austin Boulevard

Approximately 9,300 square feet of additional sidewalk area is proposed along Austin Boulevard in connection with the proposed reconstruction of this interchange (Figure 3-34). Wider sidewalks, pedestrian plaza areas, and pedestrian refuge islands between the ramps are accommodated, as well as a direct connection to the proposed east-west shared-use path. An eastward extension of the proposed shared-use path is planned to connect to the existing trail system in Columbus Park. Additional sidewalk width can also be utilized for hardscape/street furniture/aesthetic features if implemented by the local community.

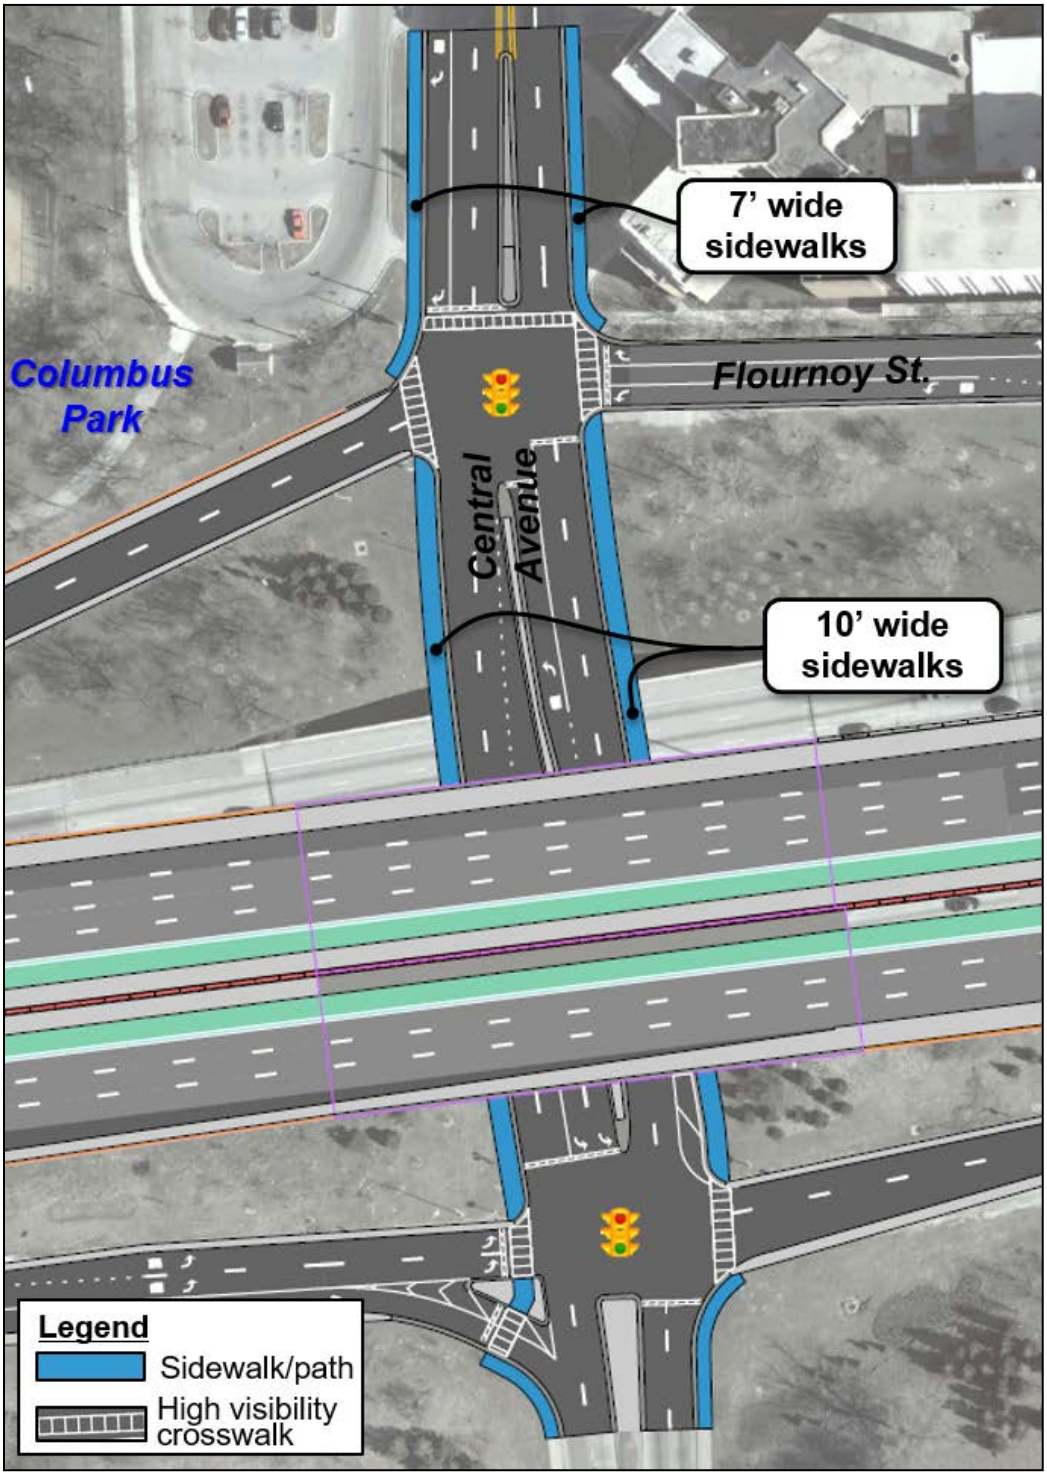

Figure 3-34. Austin Boulevard Pedestrian and Bicycle Facility Improvements

Central Avenue

Ten-foot-wide sidewalks between the ramps are proposed to provide additional walking space behind the curb, increasing the buffer distance and reducing the likelihood of conflicts between pedestrians, bicyclists, and motor vehicles (Figure 3-35).

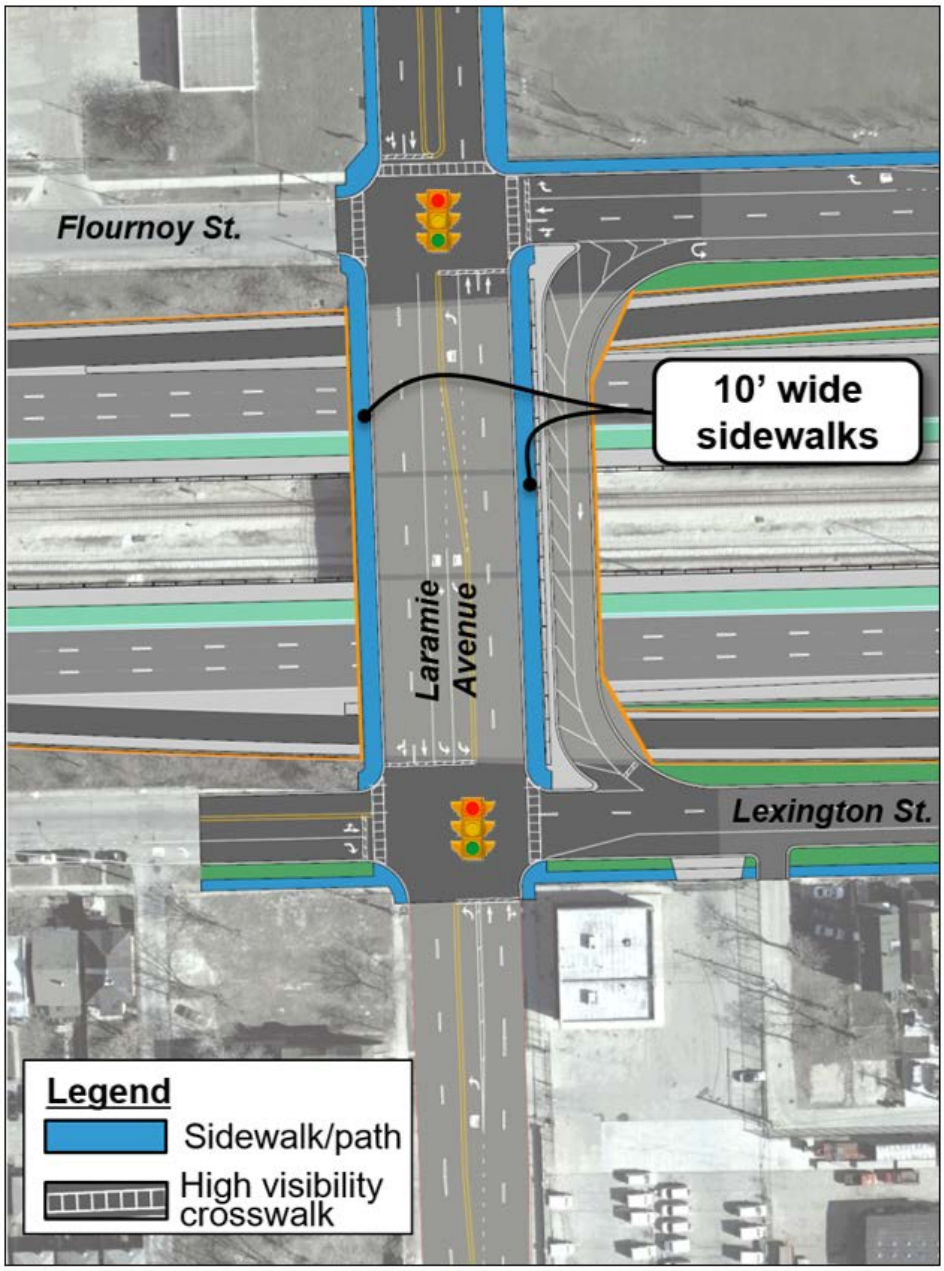

Figure 3-35. Central Avenue Pedestrian and Bicycle Facility Improvements

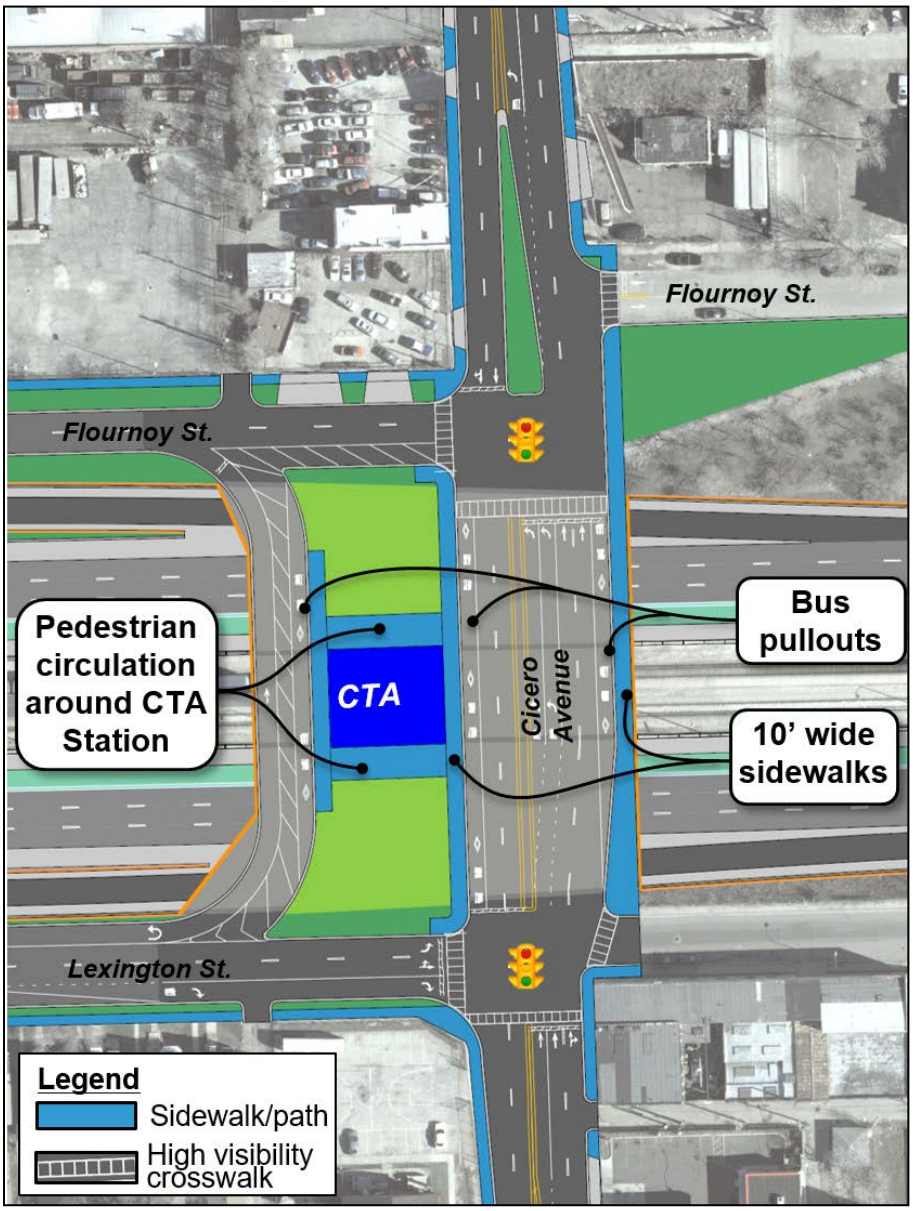
Laramie Avenue

The reverse diamond interchange design with U-turns provides improved north-south pedestrian access along Laramie Avenue by accommodating 10-foot-wide sidewalks between Flournoy Street and Lexington Street (Figure 3-36). To the north, the sidewalks along both sides of the street would be reconstructed in-kind to Harrison Street.

Figure 3-36. Laramie Avenue Pedestrian and Bicycle Facility Improvements

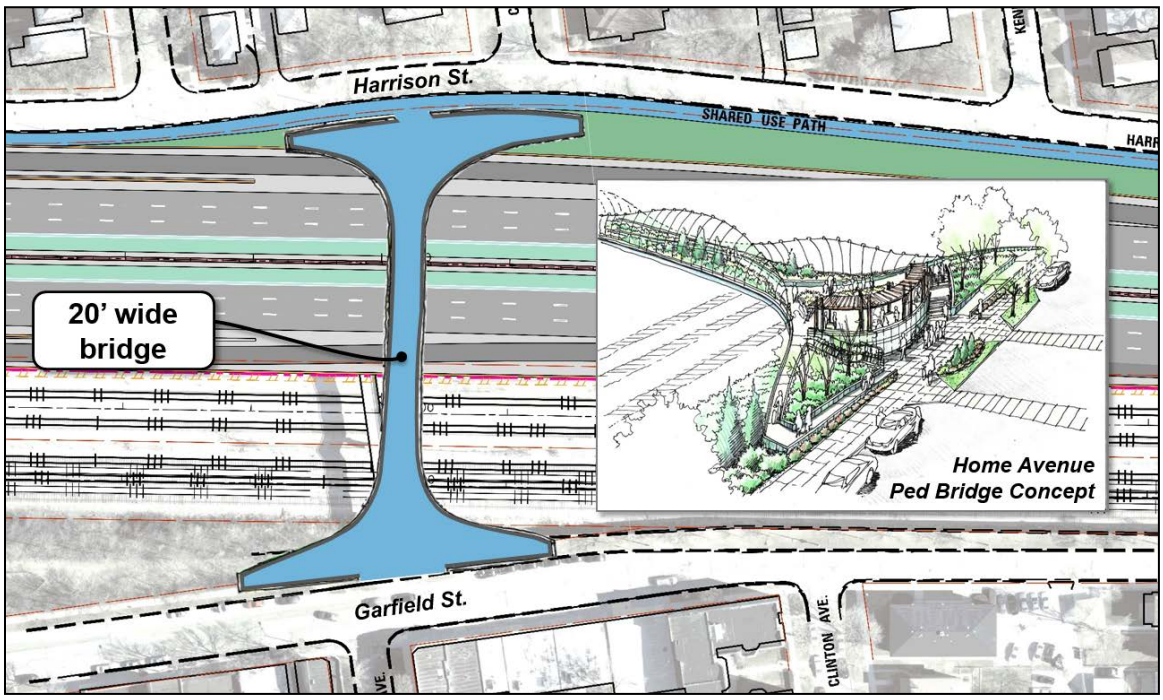


Cicero Avenue

The reverse diamond interchange with U-turns design provides improved north-south pedestrian access along Cicero Avenue, accommodating wider 10-foot-wide sidewalks across the bridge between Flournoy Street and Lexington Street (Figure 3-37). A CTA Blue Line station entrance is located on the west side of Cicero Avenue between the proposed frontage road U-turn bridge over I-290 and Cicero Avenue.

Bus lanes and stops are proposed along the west and east side of Cicero Avenue, in front of, and directly across from the CTA Blue Line station entrance. The bus pullouts and proposed crosswalks provide improved shorter and safer bus-rail transit transfers.

Figure 3-37. Cicero Avenue Pedestrian and Bicycle Facility Improvements



Pedestrian Bridges

Home Avenue Pedestrian Bridge

The Home Avenue pedestrian bridge crossing is located in the Village of Oak Park between Harlem Avenue and Oak Park Avenue (Figure 3-38). Based on coordination with the Village of Oak Park, the proposed baseline pedestrian bridge design would be 20 feet wide with 10-foot-wide access ramps at minimum to accommodate maintenance equipment. The bridge would include improved lighting and ADA-accessible access ramps that could accommodate other Village-implemented aesthetic improvements, such as a linear park or other landscape/hardscape features. The aesthetic features/ landscaping are subject to further coordination and analysis, as well as cost participation and maintenance requirements.

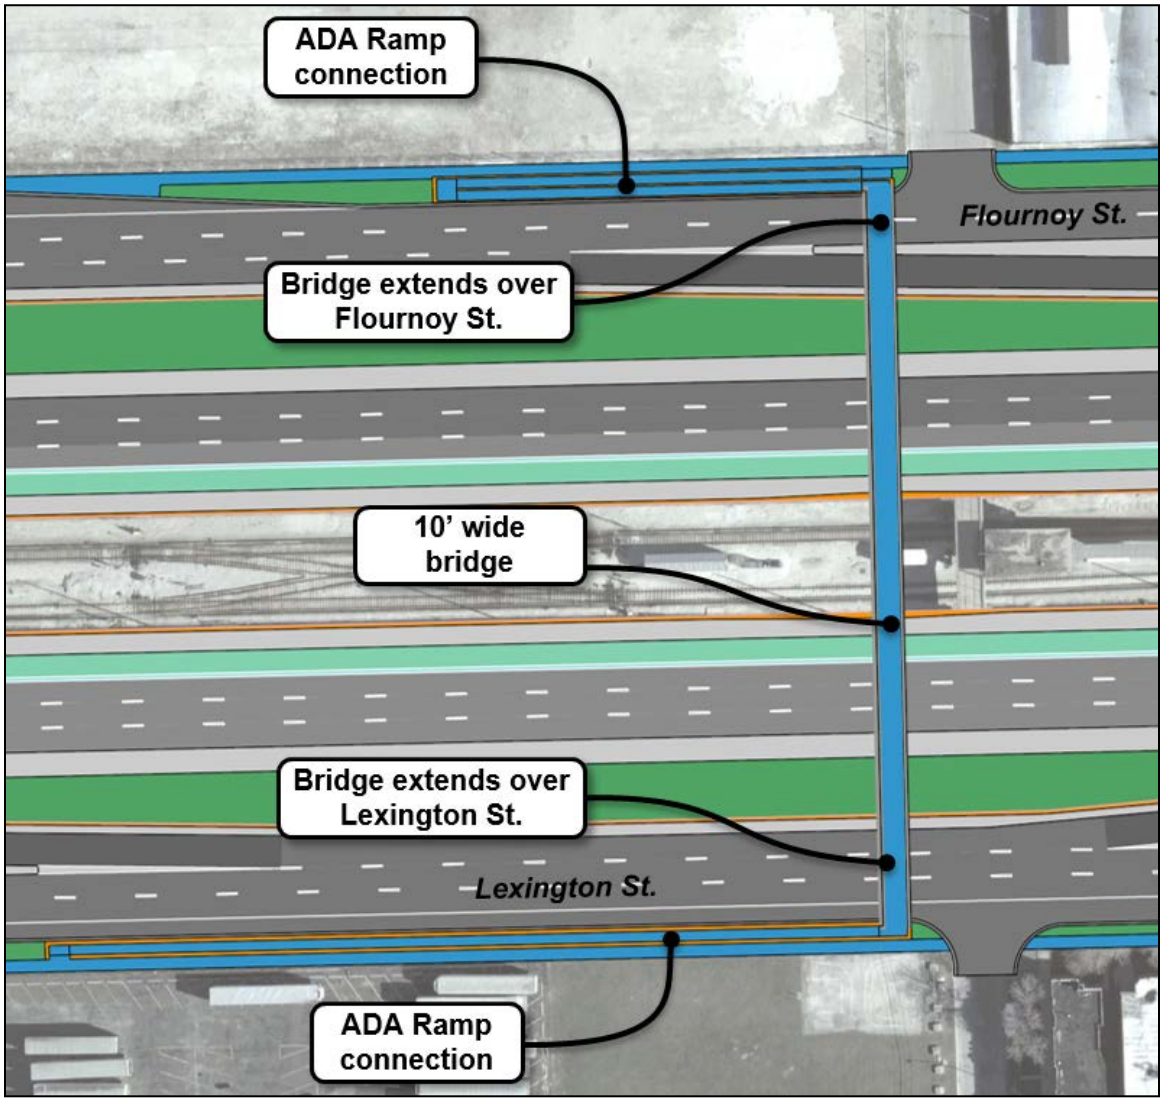


Figure 3-38. Home Avenue Pedestrian Bridge

Lavergne Avenue Pedestrian Bridge

The Lavergne Avenue pedestrian bridge is located in the City of Chicago between Laramie Avenue and Cicero Avenue (Figure 3-39). The proposed bridge would be elevated and lengthened to extend over Lexington Street (south of I-290) and Flournoy Street (north of I-290). The proposed bridge would be 12 feet wide and would include ADA-accessible ramp connections that would tie to the existing sidewalk on the north side of Flournoy Street and to the existing sidewalk on the south side of Lexington Street.

Figure 3-39. Lavergne Avenue Pedestrian Bridge

Shared-Use Path – Illinois Prairie Path Extension

As part of the proposed mainline and crossroad improvements, a new 2-mile-long shared-use path is provided along the north side of I-290 between DesPlaines Avenue and Austin Boulevard (Figure 3-40). The shared-use path would effectively extend the Illinois Prairie Path 2 miles from the CTA Blue Line Terminal in Forest Park to Columbus Park, located on the east side of Austin Boulevard in the City of Chicago.

Figure 3-40. New Shared-Use Path

At the west end, a dedicated bridge would provide a grade-separated crossing of the path over DesPlaines Avenue to connect to the existing eastern terminus of the Illinois Prairie Path (Figure 3-27). The 10-foot-wide path would then extend to the east along the north side of I-290 utilizing the additional community-level green space created by the proposed expressway realignment and retaining walls. The proposed path would generally follow the elevation of the local frontage roads to provide a nearly continuous path access along its length. The path would be grade separated below the CTA Bridge, CSX Bridge, Circle Avenue, and Harlem Avenue. Graded path connections would be provided to the sidewalks at Circle Avenue (Figure 3-28) and Harlem Avenue (Figure 3-29). East of Harlem Avenue, the shared-use path connects at grade to the Home Avenue pedestrian bridge connection and at Oak Park Avenue (Figure 3-30), East Avenue (Figure 3-31), Ridgeland Avenue (Figure 3-32), Lombard Avenue (Figure 3-32), and Austin Boulevard (Figure 3-32).

East of Austin Boulevard, the path is proposed to connect to the existing Columbus Park trail that runs along the south side of the park, which would effectively extend the reach of the Illinois Prairie Path an additional 0.5 mile to Central Avenue.

Implementation of the shared-use path pavement, lighting, and the proposed shared-use path bridge over DesPlaines Avenue is subject to local cost participation.

3.1.9 Environmental Justice

The goal of an Environmental Justice (EJ) assessment is to evaluate a proposed federal project based on potential disproportionate adverse impacts to minority and low-income populations, and make provisions so that those groups are treated fairly during (and can participate in) decision-making processes related to proposed federal projects.

FHWA Order 6640.23A defines the term "adverse effects" to include "the totality of significant individual or cumulative human health or environmental effects, including interrelated social and economic effects," which may include, but is not limited to, bodily impairment, infirmity, illness, or death; air, noise, and water pollution and soil contamination; destruction or disruption of human-made or natural resources; destruction or diminution of aesthetic values; destruction or disruption of community cohesion or a community's economic vitality; destruction or disruption of the availability of public and private facilities and services; vibration; adverse employment effects; displacement of persons, businesses, farms, or nonprofit organizations; increased traffic congestion, isolation, exclusion or separation of minority or low-income individuals within a given community or from the broader community; and the denial of, reduction in, or significant delay in the receipt of, benefits of FHWA programs, policies, or activities."

To guide federal agencies, Executive Order (EO) 12898 was put forward: "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," February 11, 1994. The Executive Order states that "each Federal agency shall make achieving EJ part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Pursuant to the Executive Order, FHWA has adopted *FHWA Order 6640.23A, FHWA Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, June 14, 2012.

In terms of transportation policy, the EJ framework contains three fundamental principles:

- To avoid, minimize, or mitigate disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority and low-income populations;
- To ensure full and fair participation by all potentially affected communities in the transportation decision-making process; and
- To prevent the denial of, reduction in, or considerable delay in the receipt of benefits by minority and low-income populations.[24]

Under FHWA Order 6640.23A, minority is defined as a person who is:

- **Black:** A person having origins in any of the black racial groups of Africa;
- **Hispanic or Latino:** A person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race;
- **Asian American:** A person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent;

[24] FHWA, 2000. http://www.fhwa.dot.gov/environment/environmental_justice/.

- **American Indian and Alaskan Native:** A person having origins in any of the original people of North America, South America (including Central America), and who maintain cultural identification through tribal affiliation or community recognition; or
- **Native Hawaiian or Other Pacific Islander:** A person having origins in any of the original peoples of Hawaii, Guam, Samoa, or other Pacific Islands.

As presented in FHWA Order 6640.23A, Hispanic or Latino populations are classified as a minority group, regardless of race. Consistent with the US Census data, Hispanic or Latino origins are considered as ethnicity data, a separate designation from race data.

According to the US Census Bureau, the terms "Hispanic" or "Latino" refer to persons who trace their origin or descent to Mexico, Puerto Rico, Cuba, Spanish-speaking Central and South America countries, and other Spanish cultures. Origin can be considered as the heritage, nationality group, lineage, or country of the person or the person's parents or ancestors before their arrival in the US. People who identify their origin as Hispanic or Latino may be of any race, consistent with FHWA Order 6640.23A. Thus, the percent Hispanic was not added to percentages for racial categories.

Under FHWA Order 6640.23A, low income is defined as a person whose median household income is at or below the HHS poverty guidelines.

3.1.9.1 Methodology

A detailed analysis was conducted for race, ethnicity, and poverty for census block groups located in the Project Corridor. The methodology for this analysis is further discussed in the Round 3 Environmental Justice Technical Memorandum (Appendix D). In conducting these assessments, available data for census block groups on population demographics were taken from the US Census. To identify concentrated racial and ethnic minority and low-income populations, 2010 Census block groups that met the following threshold criteria were classified as an EJ population of concern:

1. If the Census Block Group's population is more than 50 percent minority, ethnic group, or low-income; or
2. If the percentage of low-income population, ethnic group, or minority population in the Census Block Group is 10 percentage points higher than the percentage of low-income, ethnic group, or minority population in Cook County (the Community of Comparison).

3.1.9.2 Existing Conditions

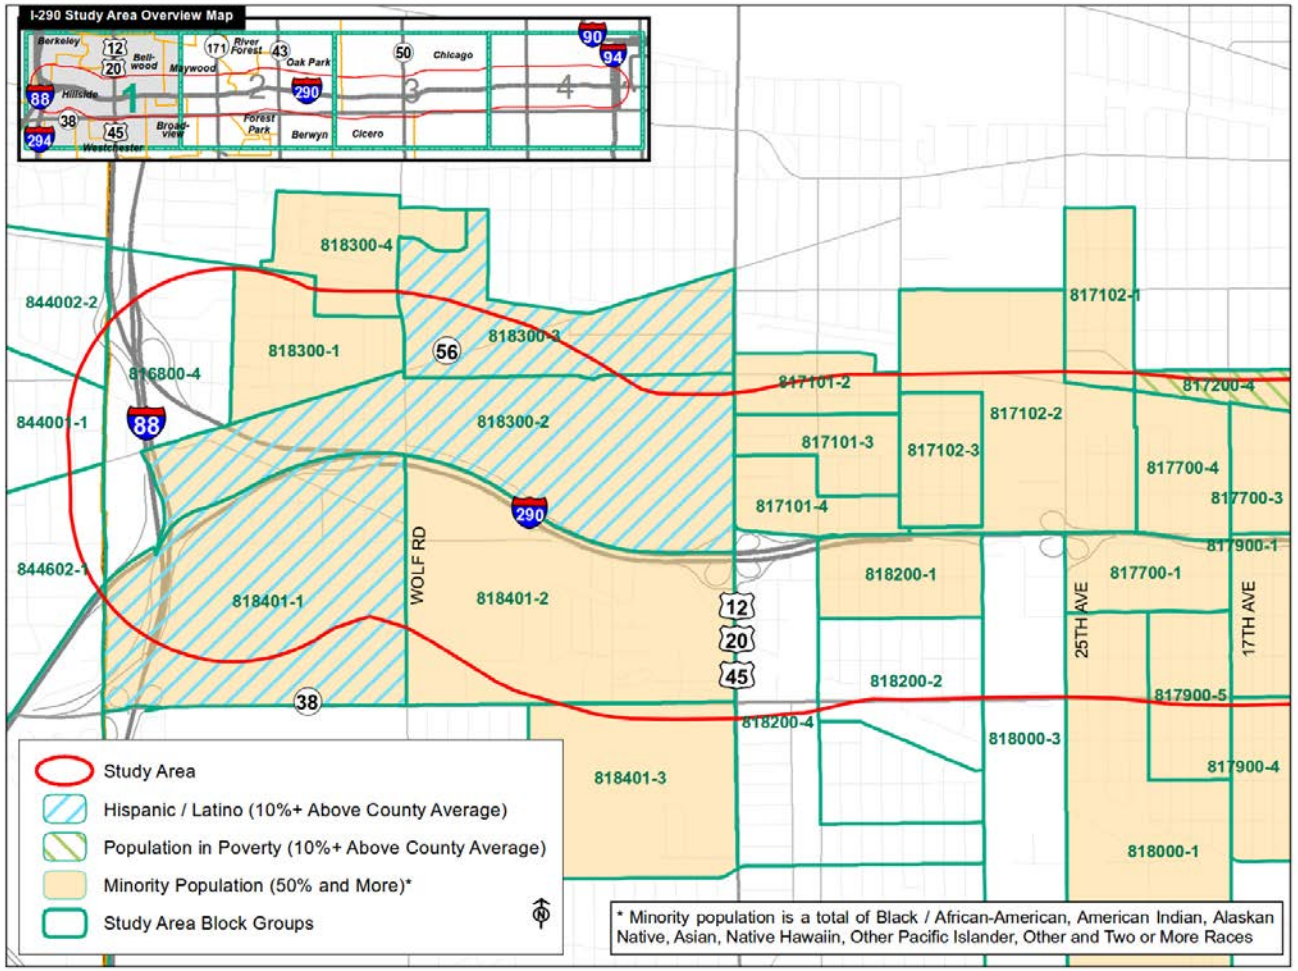
Race and Ethnicity Demographics

Using guidance from FHWA Order 6640.23A, populations are identified by race at the Census Block Group level. For the proposed project, the data are aggregated as White, Black, Asian, American Indian and Alaska Native, Native Hawaiian and Pacific Islander, Other Races, and those identified by two or more races.

As described in FHWA Order 6640.23A, along with race, ethnicity is classified as a separate minority population category. In the US Census data, Hispanic or Latino Ethnicity is a separate designation from race that may be selected in combination with any Race designation. The FHWA Order contains language consistent with the US Census designation of Hispanic or Latino.

In general, an EJ analysis is conducted by looking at minority groups singularly to identify if there is a large portion of one population subgroup in a census tract (map sets of the geographic distribution of each minority group and low-income populations can be found in Appendix D).

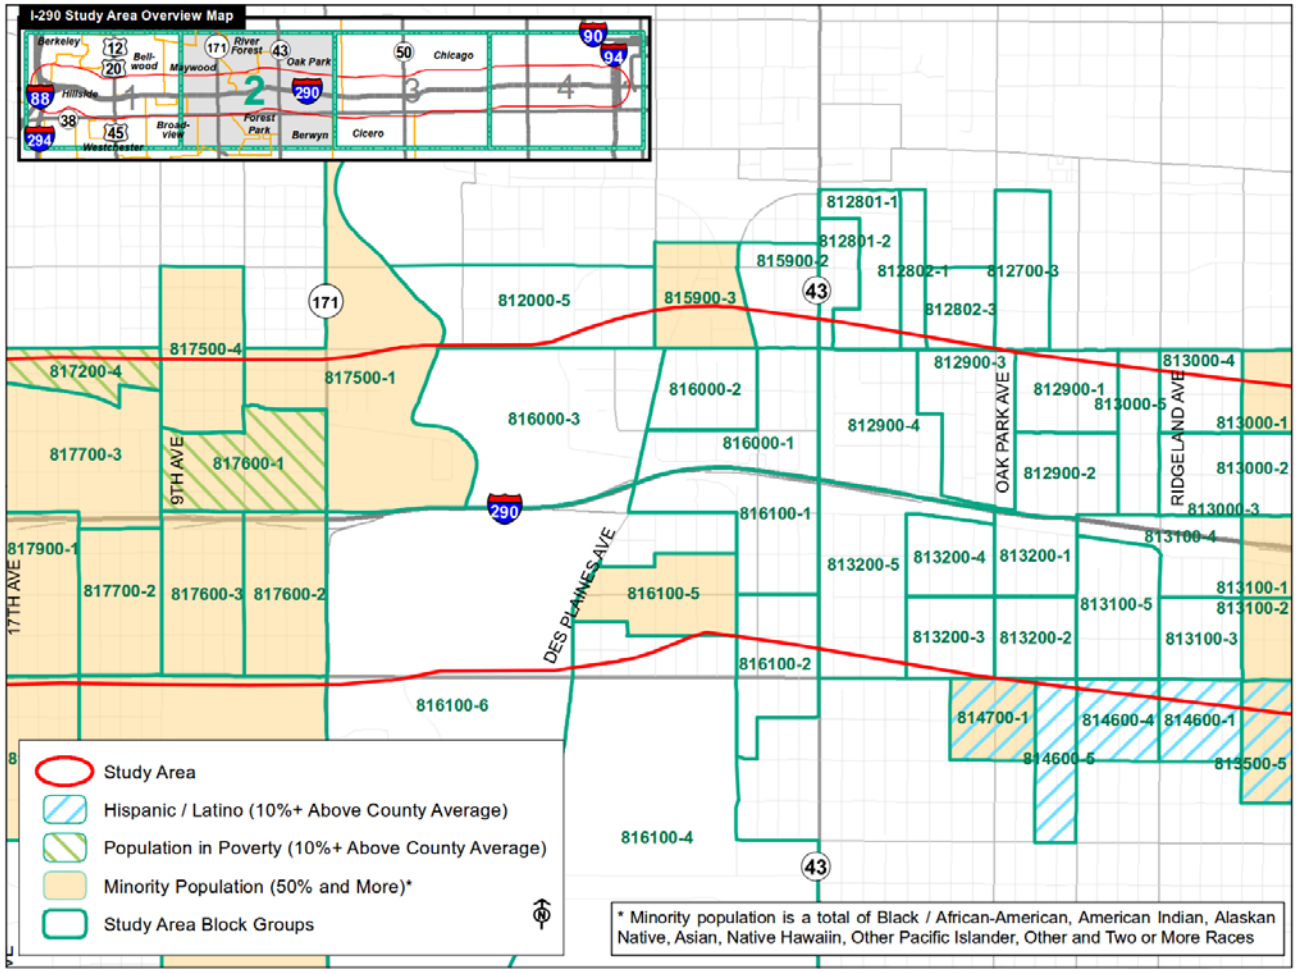
3.1.9.3 Composite Analysis of Minority, Ethnic, and Low-Income Populations



It is important to look beyond a singular population subgroup when conducting an EJ analysis. In dense and diverse corridors, such as the Project Corridor, it is essential to combine all three population types (minority, ethnicity, and low income) to identify locations throughout the corridors where diversity, and potentially low-income status, may add additional EJ populations to the study that would not be considered when conducting an analysis of a single population subgroup.

Figure 3-41 through Figure 3-44 present a composite of minority, ethnicity, and low-income status for the Project Corridor. The EJ Population composite maps show the consistency of EJ populations throughout the Study Area, with the exception of portions of Westchester, between Mannheim Road and 25th Avenue south of I-290, most of the areas between 1st Avenue and Austin Boulevard, and some areas east of Ashland Avenue. Most block groups east of Austin Boulevard are both minority EJ populations and low-income EJ populations.

3.1.9.4 Evaluating Environmental Justice



The remainder of this section focuses on addressing these three principles within the context of the No Build Alternative and build alternatives for the I-290 Study.

Public Outreach to Environmental Justice Communities

The project team worked to ensure full and fair participation by all potentially affected communities in the decision-making process. For example, three public meetings were held (Public Meeting 1 – November 18, 2009; Public Meeting 2 – May 18, 2011; and Public Meeting 3 – October 7 and 8, 2013) to inform the public of the ongoing project developments, and to engage and solicit feedback from the public regarding the proposed project. Special effort has been made to advertise all of the public meetings in EJ communities throughout the Study Area. In addition to the regular notices in newspapers, libraries, and public agency offices, advertisements were placed in places of worship, laundromats, and local convenience stores. All facility logistics were ADA compliant, easily accessible by public transportation, and located near the areas identified as EJ communities. Additionally, Spanish translation services were available at each meeting.

Other means of communicating and coordinating with the public, including the EJ populations, have been utilized. These additional outreach efforts include:

- Use of a project website to provide information to the public and receive input and comments. This website provides a central source of project study information and is available to anyone with access to the Internet at any time. Additionally, key project information has been translated in Spanish on the website;
- Distribution of four project newsletter/fact sheets at key project milestones to all the contacts on the mailing list, including federal, state, and local officials; special interest groups; resource agencies; business and community leaders; and members of the public (Fall 2009, Spring 2011, Spring 2013, and Fall 2014);
- Utilization of press releases, media briefings, publication pieces, media correspondence, and media briefings with agency-designated spokespersons to inform the general public about the proposed project and its progress. To specifically reach minority populations regionally, the press releases were sent to targeted radio, print, and television outlets; and
- Focused outreach in the Village of Maywood, including multiple town hall meetings, and the formation of an Advisory Working Group (AWG) to address access issues brought about by the proposed interchanges between 25th and 1st avenues.

Primary concerns from EJ communities are access to I-290 and the desire to directly benefit from reconstruction of the Eisenhower Expressway in the form of jobs and job training. To address I-290 access concerns, the Maywood Advisory Group was formed. To address the jobs potential of the project, there have been representatives from IDOT's community college career training program at the I-290 Study public meetings. IDOT has also been invited to speak on the I-290 Study at four town hall meetings and a civic group meeting since 2009. Other EJ concerns expressed at meetings include economic and business impacts (existing I-290 access would be maintained and 1st Avenue interchange operations would be improved); community connectivity (1st Avenue interchange and 5th, 9th, and 17th avenue I-290 cross-road bridges would have wider sidewalks and improved bicycle, ADA, and pedestrian facilities); Maywood residential

drainage/flooding issues due to undersized combined storm and waste water sewer system (proposed I-290 drainage improvements have potential for reducing flooding in 141 acres in Maywood); access to transit (wider sidewalks and improved ADA and pedestrian facilities would improve CTA station access); and financial impacts on the residents (shorter and quicker access to jobs with I-290 improvements).

Travel Demand Model:

A Travel Demand Model helps estimate and answer:

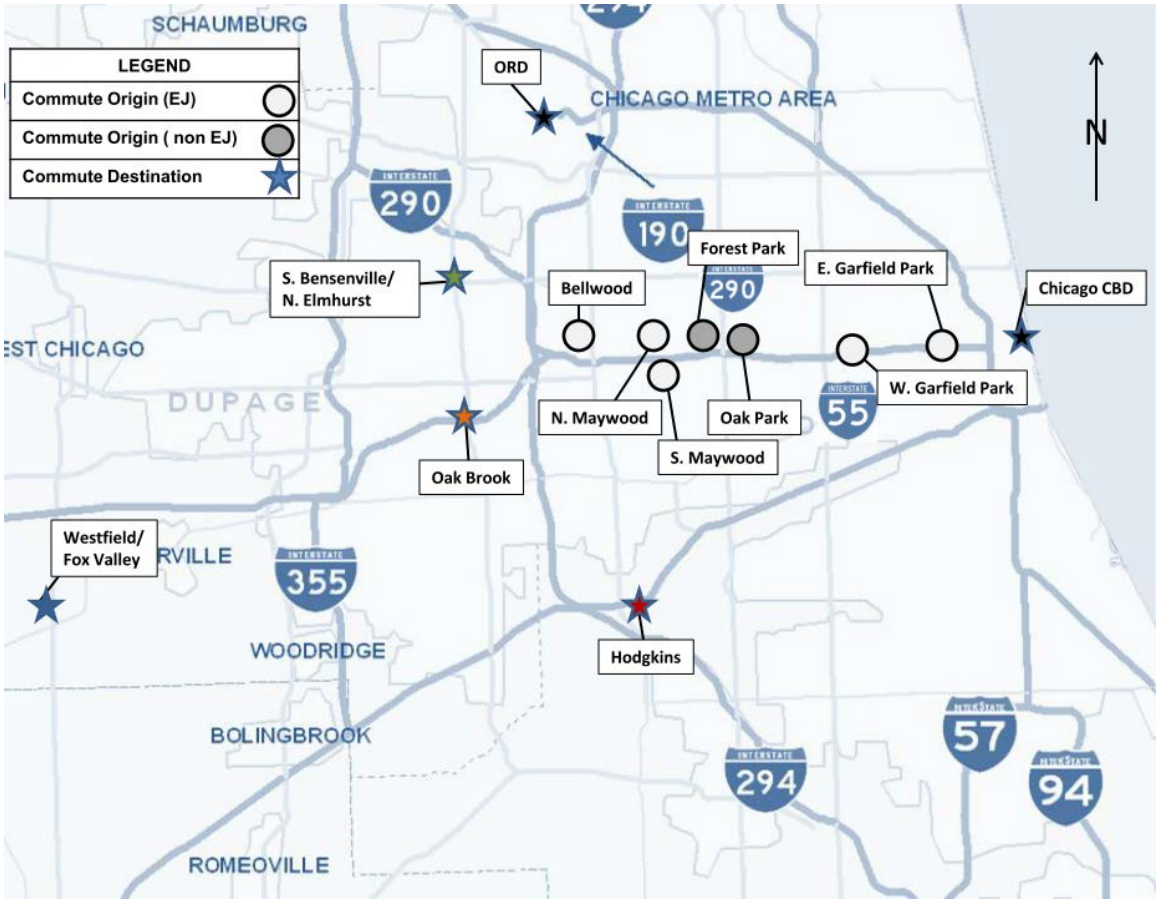
- How many trips will people take?
- Where will jobs and people locate?
- How will people travel (e.g., car, carpool, bus, train)?
- What route will people take?

Impacts Analysis to EJ Populations

The project team spent substantial effort on avoiding, minimizing, and mitigating high and adverse human health and environmental effects (including social and economic effects) on minority and low-income populations. There are no residential or commercial displacements within EJ communities; access to and within the EJ communities is not being reduced; and IDOT has responded to the concerns of EJ communities (the Village of Maywood in particular). As a result, no disproportionately high and adverse impacts to EJ populations are anticipated for any of the build alternatives. This section discusses the range of potential effects to EJ populations by discussing accessibility and mobility, safety, tolling, environmental effects, social, and economic effects.

Accessibility and Mobility

The project's build alternatives would improve accessibility and mobility to all the communities along the Project Corridor. Detailed analysis was performed using a Travel Demand Model to examine how the build alternatives affect:



- Access to employment centers;
- Transit service, bicycle facilities, and pedestrian facilities;
- Access to and from the highway between 25th and 1st avenues (where the access changes take place); and
- Localized traffic on the neighborhood arterial system.

Access to Employment Centers

All of the build alternatives offer increases in average travel speed on I-290 through the length of the Project Corridor in the AM and PM peak periods compared to the 2040 No Build Alternative. The improved speeds on the expressway relative to the 2040 No Build Alternative would be a benefit to EJ populations, because they would be able to travel quicker to and from their destinations.

An additional analysis of access to employment centers was completed by comparing travel times from different origin and destination (O/D) pairs in the Study Area for all the build alternatives (Figure 3-45 shows the origin and employment destination locations). For this analysis, the study's travel demand model was used. Trips were estimated for communities with high EJ populations, as well as communities with a low EJ component (referred to as "EJ" and "non-EJ" for the purposes of this analysis). Table 3-21 shows the average job commute time savings for five EJ communities and two non-EJ communities for each build alternative compared to the 2040 No Build Alternative.

Figure 3-45. Origins and Job Destinations for EJ and non-EJ Communities

Source: WSP Parsons Brinckerhoff, 2015.

Table 3-21. Job Accessibility Travel Time Comparison between No Build and Build Alternatives (Average of Six Job Destinations)

Origin Community	2040 No Build Travel Time (min.)	Travel Time Difference per Build Alternative (min.)			
		GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
EJ Communities					
E. Garfield Park (GP Lanes)	52	-2	-2	-2	-8
E. Garfield Park (Managed Lanes)	--	--	- 9	-10	-8
W. Garfield Park (GP Lanes)	51	-3	-2	-2	-7
W. Garfield Park (Managed Lanes)	--	--	- 8	-8	-8
N. Maywood (GP Lanes)	37	-1	-1	-1	-2
N. Maywood (Managed Lanes)	--	--	- 4	-4	-3
S. Maywood (GP Lanes)	35	-1	-1	-1	-3
S. Maywood (Managed Lanes)	--	--	- 2	-2	-1
Bellwood (GP Lanes)	34	-2	0	-1	-9
Bellwood (Managed Lanes)	--	--	-8	-8	-9
Non-EJ Communities					
Oak Park (GP Lanes)	45	-2	-2	-2	-4
Oak Park (Managed Lanes)	--	--	- 5	-5	-6
Forest Park (GP Lanes)	40	-2	-2	-2	-4
Forest Park (Managed Lanes)	--	--	- 5	-5	-6

Source: WSP Parsons Brinckerhoff, 2015.
Notes: Only one job destination (Chicago CBD) was studied for Bellwood because of the village's location at the western end of the I-290 Study Area; six job destinations were studied for all other communities. For the HOT 3+ & TOLL Alternative, "GP Lanes" refers to the tolled, non-HOV lanes.

Summary

For both the eastbound and westbound commuting trips, the build alternatives would offer travel time savings to all the EJ communities. For eastbound commuting trips to the Chicago CBD, the build alternatives would generally offer more travel time savings for the EJ communities located farthest from the CBD (North and South Maywood and Bellwood) compared to the nearby EJ communities of East and West Garfield Park. For the non-EJ communities of Forest Park and Oak Park, similar patterns are evident for trips to the CBD.

For westbound commuting trips (or reverse commute) to suburban employment cluster locations, the build alternatives would generally offer more travel time savings for the EJ

communities located farthest from the suburban employment clusters (East and West Garfield Park) compared to the nearer EJ communities of North and South Maywood. For the non-EJ communities of Forest Park and Oak Park, similar patterns are evident for trips to the suburban employment cluster locations. As both Oak Park and Forest Park are located toward the center of the Project Corridor, little difference in performance would be expected in the westward direction among the two communities.

The managed lanes of the HOV 2+, HOT 3+, and HOT 3+ & TOLL alternatives generally offer the greatest commuting time savings to all users, including the EJ communities, while GP lanes of all alternatives offer more modest time savings. In some isolated cases from a community to a particular job location, the GP lanes offer unchanged or slightly longer commuting times compared to the No Build Alternative. The tolled lanes of the HOT 3+ & TOLL Alternative also have relatively high time savings compared to the No Build Alternative. It is noted that the HOT 3+ & TOLL Alternative is the most restrictive alternative with a requirement of three or more occupants to qualify for toll-free access to I-290, which could be a deterrent to low-income use for users who could not afford the toll or meet the HOV ridership criteria. The other managed lane alternatives offer three free, unrestricted lanes, and a fourth lane that can be accessed with no toll for vehicles meeting the occupancy requirements of two to three persons.

Overall, the commute travel times did not indicate a disproportionate impact to EJ communities, as all communities receive travel benefits from the build alternatives. Refer to the "Tolling" discussion later on in this section which describes the potential effects of toll costs on EJ populations.

Transit, Bicycle, and Pedestrian Changes

As mentioned previously, the four build alternatives all include reconstruction of I-290 from just east of Cicero Avenue to the I-88 interchange, which would include the reconstruction of all overpasses (both roadway and pedestrian), except for Mannheim Road and Westchester Boulevard. Reconstruction of the overpasses would incorporate IDOT and local community provisions (which would be determined as the design progresses), Complete Streets policies, and wider sidewalks and bicycle facilities as part of any improvement. The proposed overpass improvements included in all four build alternatives would benefit access to the following existing CTA Forest Park Branch stations:

- Cicero Station – Bus transfers from two CTA routes occur at this station;
- Austin Station – Both Pace Bus and CTA have bus routes and Blue Line transfers on Austin Boulevard;
- Oak Park Station – Pace Bus operates along Oak Park Avenue with transfers at the Blue Line station;
- Harlem Station – Pace Bus operates along Harlem Avenue with transfers at the Blue Line station; and
- Forest Park Station – Pace Bus operations include both local and express bus transfers at the Forest Park CTA Blue Line terminal.

These stations, with the exception of the Oak Park Station, all serve EJ communities in the Project Corridor.

Transit travel time improvements would also result from the build alternatives. For the GP Lane Alternative, buses on the shoulders of I-290 are proposed west of the Forest Park Station. For the HOV 2+, HOT 3+, and HOT 3+ & TOLL Alternatives, express buses would use the managed lane on I-290 west of the Forest Park Station. These express bus services would see greater reliability and travel time improvements using the shoulder/managed lane.

All proposed improvements to I-290 would be designed in consideration of pedestrian and bicycle users for the communities within the Project Corridor. None of the pedestrian and bicycle improvements would adversely affect EJ communities. They would result in improved mobility across I-290 at the interchange connecting points and in accessibility to adjacent arterials. Appropriate safety and ADA features would be applied uniformly based on established design guidelines.

The project's design would include improved bicycle access and improved bicycle- and pedestrian-only crossings. In addition, a new east-west multi-use path would be provided between DesPlaines Avenue and Austin Boulevard (a distance of approximately 2 miles), providing an additional nonmotorized travel option separated from vehicular traffic, and providing a transportation link to EJ communities located to the east and west of the path termini. Bicycle access would be incorporated into the project's design, consistent with Complete Streets guidance or other standards that may apply. As such, future design conditions of existing cross streets would not preclude bicycle use at a later time should the affected community choose to accommodate future use.

Relating to pedestrian facilities, all sidewalks on cross streets over I-290 are proposed to be 7 to 16 feet wide depending on the location, which is consistent with, or exceeds, IDOT's Complete Streets guidance in the BDE Manual (2010).

Access to/from the Highway

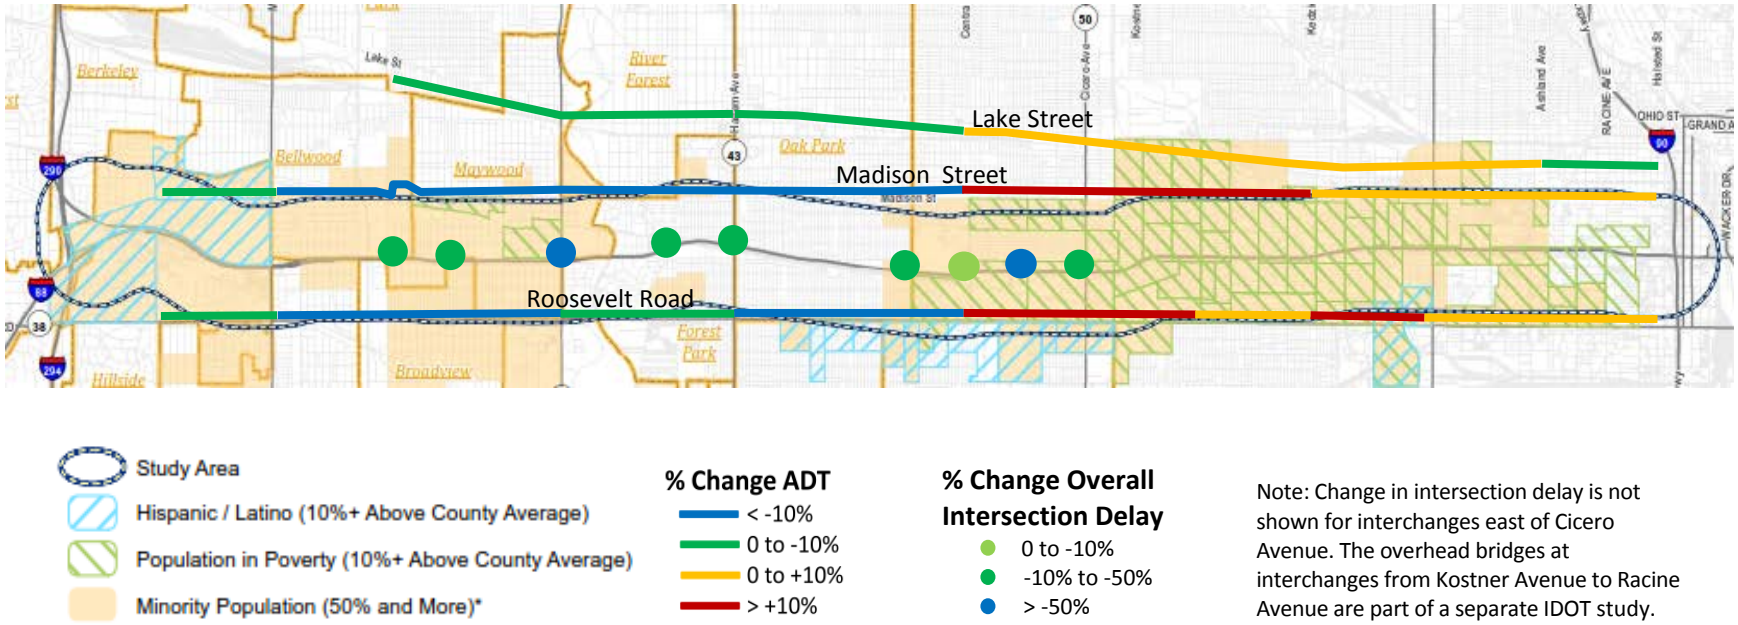
Access to and from the highway is improved by the build alternatives due to proposed improvements at each of the highway interchanges. Improved geometry, additional turning lanes, and improved signal timing all work to improve highway access to and from the communities for the interchanges in the Reconstruction Section.

Arterial Traffic

As previously presented in Section 3.1.8.2, Impacts to Transportation, overall Project Corridor arterial travel performance of the build alternatives compared to the 2040 No Build Alternative shows that the HOT 3+ & TOLL Alternative is expected to attract more traffic and increase congestion, with higher VMT and VHT compared to the No Build Alternative. This is due to diversion of I-290 traffic to the arterial system from tolling all lanes on I-290. The other three build alternatives have improved arterial performance compared to the 2040 No Build Alternative.

An analysis of the changes to arterial system performance relative to the geographic location of the EJ communities was performed. The forecasted change in 2040 east-west arterial ADT for each build alternative, relative to the No Build Alternative, is an indication of benefit for moving traffic from the arterial roadways back to I-290. In some cases, this improved mobility attracts growth in population and jobs, which provides economic benefit, but it can also bring new traffic demand. For example, east of Cicero Avenue, there is an increase in forecasted Study Area population of 1,502 people and 417 jobs in the build scenario, but also a corresponding slight increase in arterial traffic (Figure 3-46 through Figure 3-49).

The forecasted change in arterial roadway traffic between the build and no build scenarios was overlaid on the mapped Project Corridor minority and low-income EJ communities (shown previously in Figure 3-41 through Figure 3-44). In addition, projected north-south arterial performance was examined based on the percent change in overall intersection delay at proposed new I-290 interchange configurations compared to the No Build Alternative. This was also overlaid on the Project Corridor minority and low-income EJ community mapping. Figure 3-46 through Figure 3-49 show the results of the arterial performance for each of the four build alternatives.



Decrease Traffic on Local Streets

Reducing congestion on nearby east-west streets is a positive benefit of the I-290 build alternatives. As discussed on the next four pages, many vehicles currently use local, east-west streets (e.g., Madison Street, Roosevelt Road) to avoid the I-290 congestion. Because the project would relieve congestion on I-290, many of those vehicles that currently congest the local streets would, in the future, travel on the expressway instead of the local east-west streets.

Safety

A quantitative safety analysis was performed on the No Build Alternative and the four build alternatives. Expressway, arterial, and overall (auto and transit modes) safety performance was predicted and used to identify any disproportionate impacts to EJ populations. Of the four build alternatives, the HOV 2+ and HOT 3+ Alternatives are projected to provide the greatest projected crash reduction from the 2040 No Build Alternative at -6.44 percent and -6.21 percent, respectively, while the GP Lane and HOT 3+ & TOLL Alternatives provide the least overall crash reduction at -4.86 percent and -4.65 percent, respectively. All of the build alternatives provide safety benefits over the No Build Alterative.

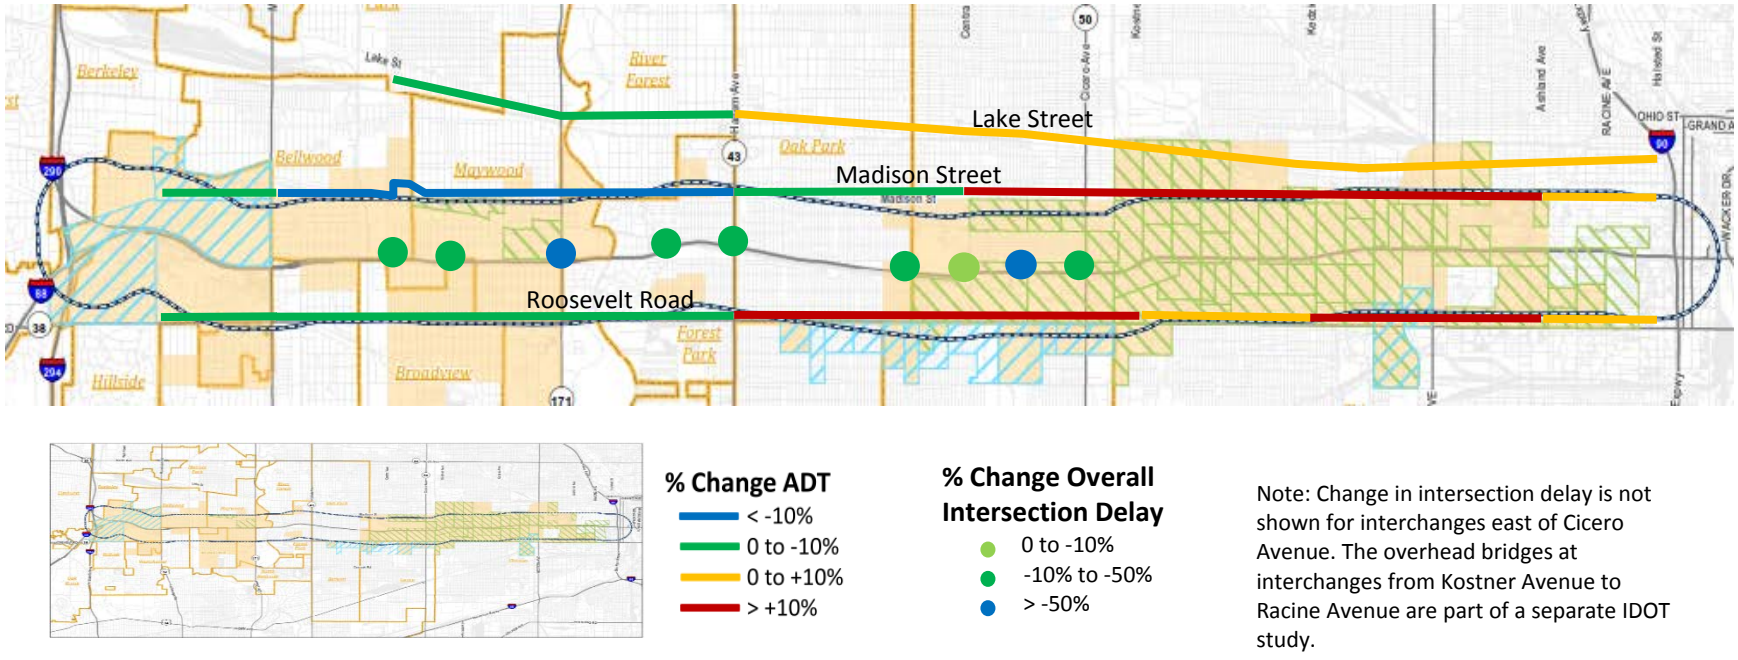


Figure 3-46. GP Lane Alternative Projected East-West Arterial ADT Change and North-South Arterial Intersection Delay Change at I-290 Interchanges Compared to the No Build Alternative and EJ Communities

Source: WSP Parsons Brinckerhoff, 2015.

For the GP Lane Alternative, east-west arterial ADT on Madison Street and Roosevelt Road decreases through EJ communities in Bellwood, Westchester, Broadview, Maywood, Forest Park, and Oak Park, west of Central Avenue, compared to the No Build Alternative. However, ADT for both streets, as well as Lake Street, increases east of Central Avenue through EJ communities in Chicago, except for the section of Lake Street from Ashland Avenue to Racine Avenue where it decreases in comparison to the No Build Alternative. All intersections at the seven proposed reconstructed interchanges in or adjacent to EJ communities (25th Avenue, 17th Avenue, 1st Avenue, Austin Boulevard, Central Avenue, Laramie Avenue, and Cicero Avenue) are projected to have reduced intersection delay time, with 1st Avenue and Laramie Avenue having the highest percentage delay decrease compared to the No Build Alternative.

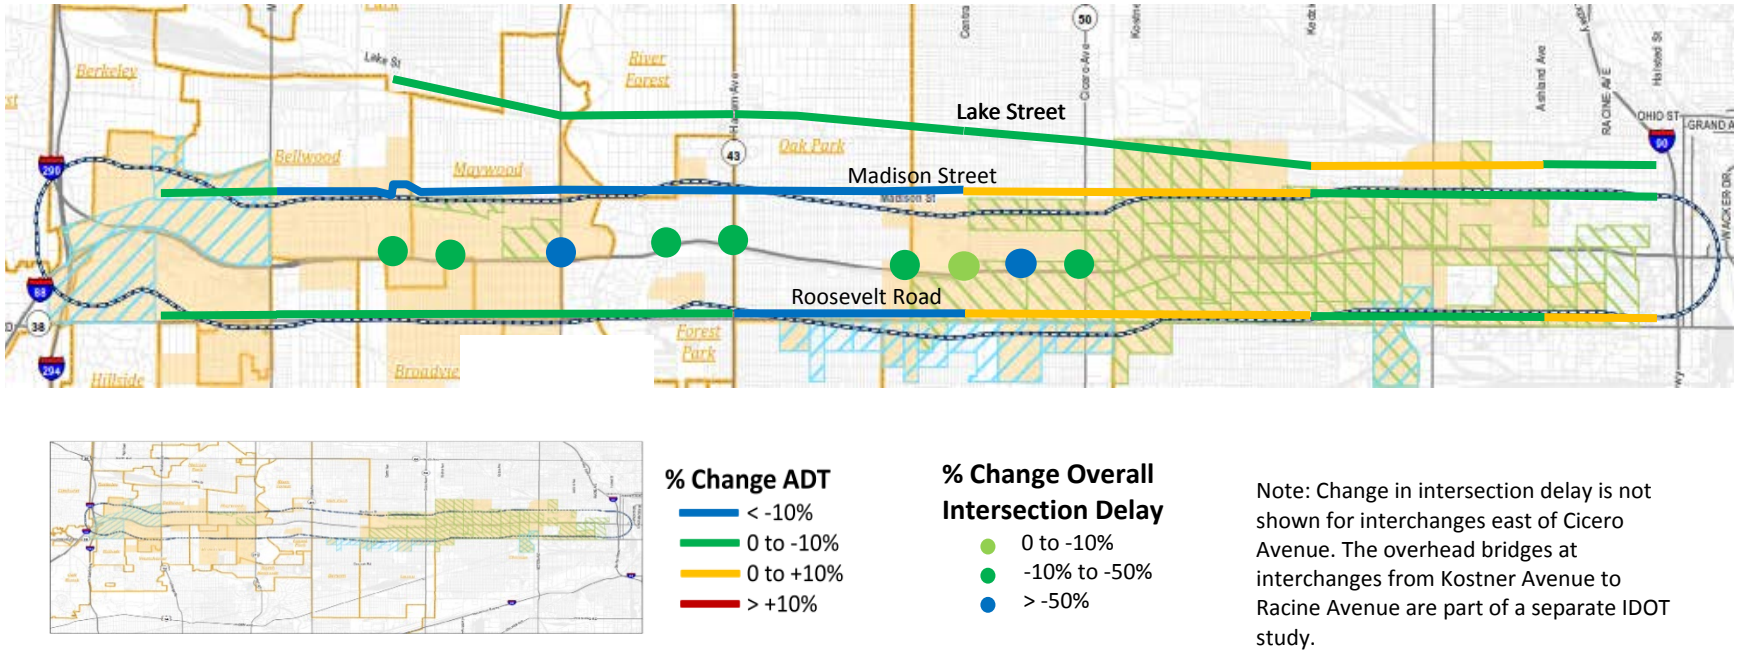

Figure 3-47. HOV 2+ Alternative Projected East-West Arterial ADT Change and North-South Arterial Intersection Delay Change at I-290 Interchanges Compared to the No Build Alternative and EJ Communities

Source: WSP Parsons Brinckerhoff, 2015.

For the HOV 2+ Alternative, east-west arterial ADT on Madison Street and Roosevelt Road decreases through EJ communities in Bellwood, Westchester, Broadview, Maywood, and Forest Park, west of Harlem Avenue, compared to the No Build Alternative. However, ADT on both streets, as well as Lake Street, increases east of Harlem Avenue through EJ communities in Oak Park and Chicago, except for the section of Madison Street from Harlem Avenue to Central Avenue where it decreases compared to the No Build Alternative. All intersections at the seven proposed reconstructed interchanges in or adjacent to EJ communities (25th Avenue, 17th Avenue, 1st Avenue, Austin Boulevard, Central Avenue, Laramie Avenue, and Cicero Avenue) are projected to have reduced intersection delay time, with 1st Avenue and Laramie Avenue having the highest percentage delay decrease as compared to the No Build Alternative.

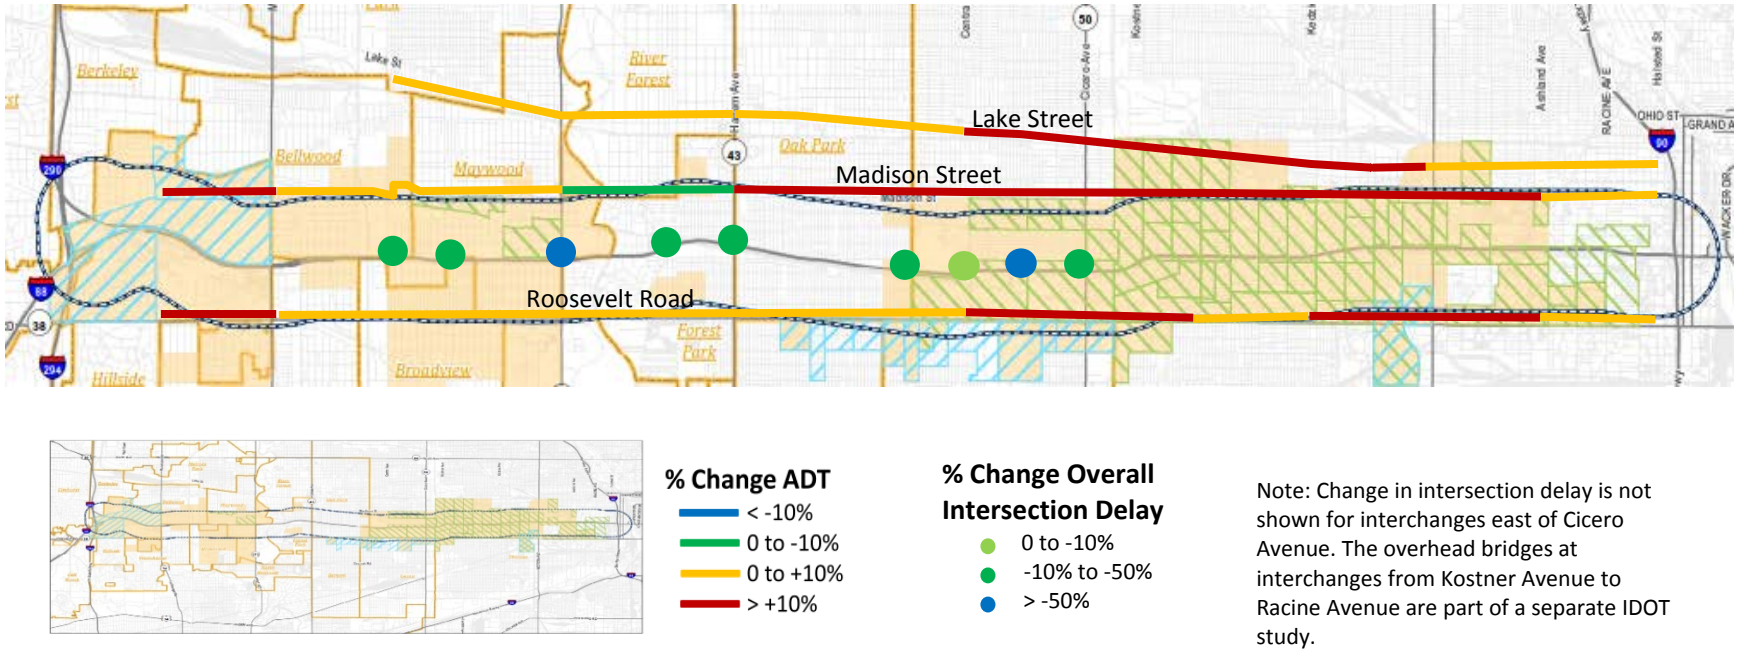

Figure 3-48. HOT 3+ Alternative Projected East-West Arterial ADT Change and North-South Arterial Intersection Delay Change at I-290 Interchanges Compared to the No Build Alternative and EJ Communities

Source: WSP Parsons Brinckerhoff, 2015.

For the HOT 3+ Alternative, east-west arterial ADT on Madison Street and Roosevelt Road decreases through EJ communities in Bellwood, Westchester, Broadview, Maywood, Forest Park, and Oak Park, west of Central Avenue, compared to the No Build Alternative. East of Central Avenue, ADT on both streets, as well as Lake Street, continues to decrease through EJ communities in Chicago, except for the sections of Lake Street from Kedzie Avenue to Ashland Avenue, Madison Street from Central Avenue to Kedzie Avenue, and Roosevelt Road from Central Avenue to Kedzie Avenue, and Ashland Avenue to Halsted Street, where it increases compared to the No Build Alternative. All intersections at the seven proposed reconstructed interchanges in or adjacent to EJ communities (25th Avenue, 17th Avenue, 1st Avenue, Austin Boulevard, Central Avenue, Laramie Avenue, and Cicero Avenue) are projected to have reduced intersection delay time, with 1st Avenue and Laramie Avenue having the highest percentage delay decrease compared to the No Build Alternative.

Figure 3-49. HOT 3+ & TOLL Alternative Projected East-West Arterial ADT Change and North-South Arterial Intersection Delay Change at I-290 Interchanges Compared to the No Build Alternative and EJ Communities

Source: WSP Parsons Brinckerhoff, 2015.

For the HOT 3+ & TOLL Alternative, east-west arterial ADT on Madison Street, Roosevelt Road, and Lake Street increases through EJ communities in Bellwood, Westchester, Broadview, Maywood, Forest Park, Oak Park, and Chicago throughout the Study Area compared to the No Build Alternative, with the exception being Madison Street between 1st Avenue and Harlem Avenue, where it decreases compared to the No Build Alternative. All intersections at the seven proposed reconstructed interchanges in or adjacent to EJ communities (25th Avenue, 17th Avenue, 1st Avenue, Austin Boulevard, Central Avenue, Laramie Avenue, and Cicero Avenue) are projected to have reduced intersection delay time, with 1st Avenue and Laramie Avenue having the highest percentage delay decrease compared to the No Build Alternative.

Tolling

A consideration for potential low-income users is the increased cost of using the tolled lanes of the HOT 3+ and HOT 3+ & TOLL Alternatives. For purposes of estimating toll cost, passenger car rates of $0.20 per mile in the AM and PM peak periods, $0.16 per mile in the "shoulder" periods (just before and after the peak periods), and $0.12 per mile in mid-day and overnight periods were used in the model. These toll rates apply to the HOT lane in the HOT 3+ Alternative and the HOT 3+ & TOLL Alternative. For the regular tolled lanes in the HOT 3+ & TOLL Alternative, a constant rate of $0.12 per mile was modeled. Table 3-22 shows the typical cost of using the build alternatives on a 13-mile trip through the length of the Project Corridor from Wolf Road to Ashland Avenue.

Table 3-22. Estimated Toll Cost per Build Alternative (Wolf Road to Ashland Avenue)

Time Period	GP All Lanes	HOV 2+ All Lanes	HOT 3+ GP Lanes	HOT 3+ Toll Lane*	HOT3+/TOLL Toll Lanes	HOT 3+/TOLL HOT Lane*
Peak	$0.00	$0.00	$0.00	$2.60	$1.56	$2.60
Shoulder	$0.00	$0.00	$0.00	$2.08	$1.56	$2.08
Off-Peak	$0.00	$0.00	$0.00	$1.56	$1.56	$1.56

Source: WSP Parsons Brinckerhoff, 2015.

* Vehicles with 3 or more occupants do not pay tolls.

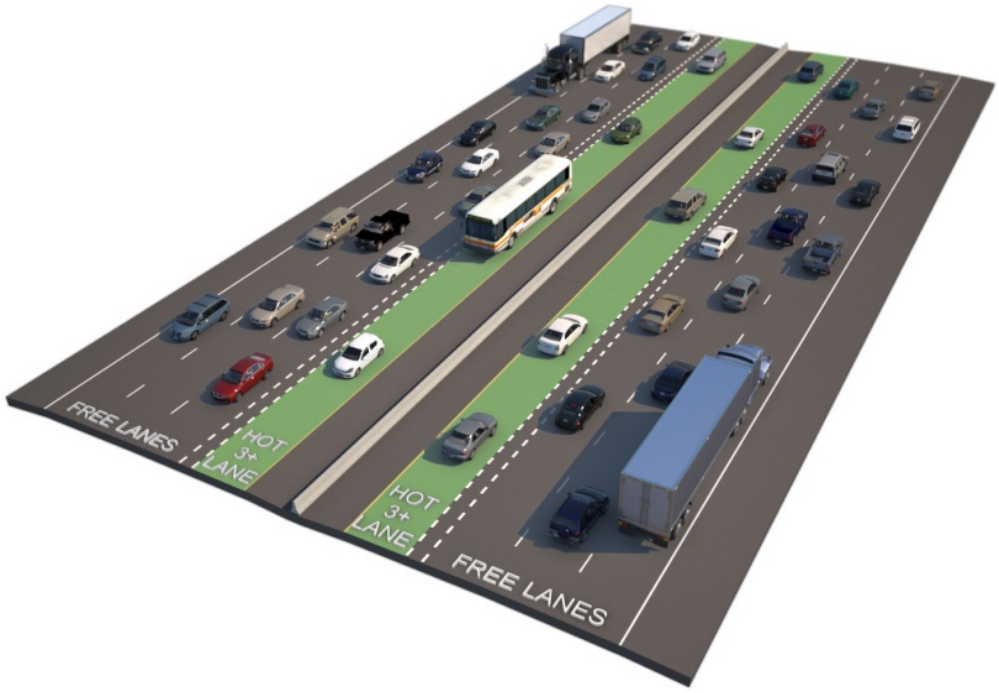
For all alternatives except the HOT 3+ & TOLL Alternative, there would be a minimum of three "free" non-tolled lanes in each direction that would also not require a minimum number of vehicle occupants. The GP Lane Alternative has four free lanes in each direction, while the HOV 2+ and HOT 3+ Alternatives have three free lanes in each direction. Figure 3-50 and Figure 3-51 show the free and managed lanes of the HOT 3+ and HOT 3+ & TOLL Alternatives, respectively.

Travel in the HOT lane for single-occupancy vehicles (SOVs) would require payment; there is growing research examining effects to low-income populations for reference.

- Public outreach initiated in Washington State on income equity found that the choice to use the State Route (SR) 167 HOT lanes was not based on income levels or ability to pay the toll. Persons interviewed by Washington State Department of Transportation (WSDOT) in the low-income focus groups specifically stated they would use the HOT lane if it provided them a shorter travel time, a reliable travel time, and was fairly priced and enforced.[25]

[25] WSDOT, http://www.wsdot.wa.gov/NR/rdonlyres/9B439F74-7CB2-46BB-A669-7684D31BDCA6/0/EJ_HotLanesPilotProjectfinal.pdf.

Figure 3-50. Free General Purpose Lanes and HOT 3+ Lanes in HOT 3+ Alternative



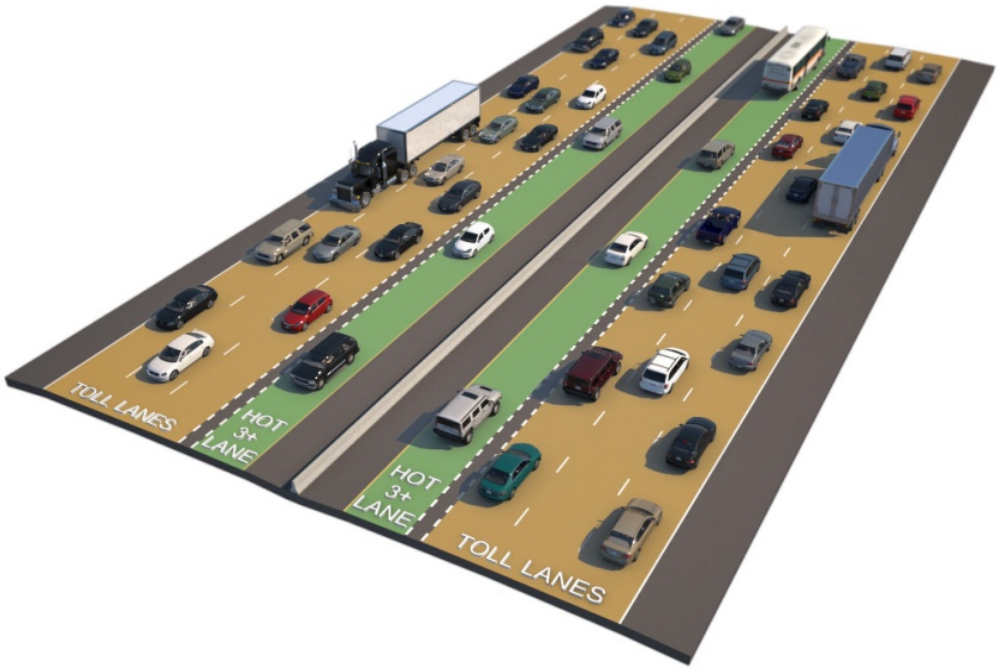


Figure 3-51. Tolled General Purpose Lanes and HOT 3+ Lanes in HOT 3+ & TOLL Alternative

- A survey conducted for the I-15 FasTrak HOT lanes in San Diego, California, showed support for FasTrak was high across all income groups, with the lowest income group expressing as much support as the highest income group (approximately 80 percent). The survey found that most I-15 users believed the project to be fair to travelers in both the main lanes and the express lanes. The survey also showed there were very few differences in attitudes about the fairness of the lanes based on ethnicity or income.[26]
- Public outreach for the implementation of I-25/US 36 HOT lanes in Denver, Colorado, did not uncover critical concerns regarding equity or other social impacts, nor have such concerns arisen since implementation.[27]
- In Minneapolis, Minnesota, surveys have found that all income groups value time savings and reliability for certain trips. Worsening congestion and a shortage of transportation funds were also important to HOT lane usage. Surveys of corridor users found a relatively small difference in income between those who do and those who do not own transponders.[28]
- Studies suggest that some low-income families choose to pay for HOT lanes to get to work on time, to keep childcare costs down, and to make appointments on time without taking as much leave from work.[29]

Potential remedial strategies for addressing greater access by low-income users to the full range of mobility options of the HOT 3+ or HOT 3+ & TOLL Alternatives include increased promotion of carpooling or vanpooling to job centers from areas of low-income populations or a toll subsidy program for low-income households. As an example, Los Angeles County has implemented an Equity Program that provides a monthly toll credit to qualifying low-income households.[30]

Environmental Effects

Air Quality

The build alternatives would result in an overall improvement to air quality compared to the No Build Alternative; therefore, no disproportionate air quality impacts to EJ populations are anticipated (Section 3.3, Air Quality, for full discussion).

Noise

Sensitive noise receptors, such as schools and residences, within the Project Corridor would be considered for noise walls to mitigate for noise impacts (Section 3.4, Traffic Noise, for full discussion).

Social and Economic Effects

The social and economic effects of the proposed build alternatives are summarized below. No disproportionate impacts to EJ populations are anticipated in regards to effects related to any of the social and economic effects.

- Displacements – The build alternatives are not expected to result in any residential or business relocations (Section 3.1.1, Population Characteristics, for full discussion).
- Community Cohesion and Community Changes – The build alternatives would improve upon the existing design of I-290, enhance community connectivity by improving access for all users across the highway, and improve roadway, pedestrian, bicycle, and transit connections. Noise walls would be included as part of this project and can improve the community by reducing noise; however, they can also block sight lines that previously existed. For example, residents of some communities that are now able to see across the I-290 corridor would not be able to in the future due to the presence of noise walls. In addition, the use of nontraditional materials such as acrylic, see-through walls would be investigated and coordinated with the various communities that are eligible for noise abatement during Phase II design.
- Population, Economic, and Employment – The build alternatives would result in minor increases in population and employment in the Study Area based on the I-290 socio-economic forecasts. The build alternatives would also result in increased productivity due to travel time savings ranging from $83 to $152 million annually in 2040.
- Land Use – The build alternatives are not expected to result in changes to land use (Section 3.1.1, Population Characteristics, for full discussion).
- Public Services and Utilities – The build alternatives are not expected to result in impacts to public services and utilities. Improvements to interchange performance and travel times with all the alternatives would improve emergency access to many areas. In Maywood, there would be drainage improvements that would help limit future flooding (Section 3.9.2.3, Local Community Coordination, for full discussion).
- Economics – The build alternatives would all result in long-term benefits associated with improved access to and from the highway (Section 3.1.2.2, Economic and Employment Impacts, for full discussion).

Parks

The build alternatives would not adversely affect Section 4(f) resources present in the Project Corridor; therefore, no disproportionate park impacts to EJ populations are anticipated (Section 3.12, Special Lands, for full discussion).

Visual

The Project would work to create a consistent corridor aesthetic and would present an opportunity to work with each of the communities in the Project Corridor to develop a plan that identifies pedestrian and aesthetic features that would enhance each crossroad

as a community asset. Noise walls would be an element in the project, as described in Section 3.4, Traffic Noise. The design of potential noise barriers would be coordinated with the local communities to achieve the desired character and aesthetic. The build alternatives are not expected to impact visual resources; therefore, no disproportionate impacts to EJ populations are anticipated (Section 3.13, Visual Resources, for full discussion).

Cultural Resources

The build alternatives are not expected to result in impacts to cultural resources; therefore, no disproportionate impacts to EJ populations are anticipated (Section 3.2, Cultural Resources, for full discussion).

Construction

The build alternatives would result in short-term construction impacts to the adjacent communities. These impacts would last the length of construction and would be equitably spread along the Project Corridor. Construction could potentially cause reroutes to CTA stations and other short-term impacts.

As shown in Figure 3-52, a series of off-system arterial improvements and the proposed I-55 Express Toll Lanes are proposed to help alleviate the short-term construction impacts by providing arterial and expressway relief routes to partially offset the reduction of I-290 expressway capacity during construction. Because these improvements would occur in all communities along the corridor, no disproportionately high and adverse impacts to EJ populations are anticipated (Section 3.14, Construction Impacts, for full discussion).

Figure 3-52. Off-System Improvements

Benefits to Environmental Justice Communities

The overarching EJ principle is to prevent the denial of, reduction in, or considerable delay in the receipt of benefits by minority and low-income populations. The following points below describe how the project would adhere to this principle:

- All of the build alternatives offer increases in average travel speed on I-290 through the length of the Project Corridor in the AM and PM peak periods compared to the 2040 No Build Alternative. For the alternatives that include GP Lanes, the GP travel times are improved over the No Build Alternative.
- For the alternatives that include a HOT lane, this lane would be accessible for no toll to carpools with three or more occupants, thereby providing a low-cost travel option to low-income users.
- The project would include off-system improvements to the nearby arterial road system (Figure 3-52) to improve travel for people who live in communities adjacent to the Project Corridor. These improvements would enhance travel through the EJ communities that currently abut I-290.
- Sidewalk widths on the streets that cross over I-290 would be improved from their existing widths. This would improve pedestrian connectivity for all the communities adjacent to the Project Corridor.
- As discussed previously in Section 3.1.2, Corridor Economic Characteristics, all alternatives provide new green space between 1st Avenue and 25th Avenue.
- The changes in access between 1st and 25th avenues would be offset by improved interchange designs at these streets, which would prevent cut-through traffic and reduce queue lengths for north-south travelers on these arterials.
- The project would give the opportunity to work with communities on a plan that identifies pedestrian and aesthetic features that would enhance each crossroad as a community asset.

3.1.9.5 Environmental Justice Summary

In summary, there are minority and low-income EJ populations in the Study Area. The project was examined to identify any disproportionately high and adverse human effects on these populations, to ensure that participation in the transportation decision-making process was full and fair, and to ensure that project benefits would be received by EJ communities in an equitable and timely manner.

To measure the effects, access to employment; nonmotorized transportation and transit access to and from I-290 between 1st and 25th avenues; and traffic effects on neighborhood arterials were examined from a transportation standpoint. Also, social and environmental factors such as community changes, noise, air quality, and historic properties were examined for disparate impacts between the EJ and non-EJ communities served by the project. The public involvement/community outreach efforts were identified, both as to location, frequency, and method of delivery.

No substantial differences in transportation access were found with any of the build alternatives with respect to EJ communities compared to non-EJ communities, and all build alternatives had benefits in job accessibility and nonmotorized and transit access for EJ communities that were similar to non-EJ communities. Of the build alternatives, the HOT 3+ & TOLL Alternative is expected to attract more traffic and increase congestion on the Study Area arterial system compared to the No Build Alternative, while the other three build alternatives showed positive effects. Environmental effects, such as those to air, noise, and social and economic resources (including construction impacts), were similar for both EJ and non-EJ communities, and no residences or businesses in either EJ or non-EJ communities are proposed to be displaced by any of the build alternatives. Public involvement was encouraged by the participation of representatives of EJ communities in the project's Corridor Advisory Group (CAG) study group, as well as traditional and nontraditional means of engaging the public in participation at public and community meetings. Though there would be impacts (noise and construction impacts in particular) to EJ and non-EJ communities along the Study Area, upon implementation of the planned mitigation, as described in this EIS, and coordinated with each community, the impacts would not be disproportionately high and adverse to EJ communities.

3.2 Cultural Resources

Since publication of the DEIS, the following substantive changes to this section have been made:

- Updated Section 3.0 Map Set with corrected historic property boundaries for the Hulbert Historic District, the Park District of Forest Park, and Garfield Park;
- Updated Section 3.2.1 "Consultation" to summarize the April 11, 2017 consulting parties meeting about the assessment of effects to historic properties;
- Added an "Effect Determination" column to Table 3-23 and Table 3-24 to provide the effect finding for each National Register of Historic Places (NRHP)-listed and NRHP-eligible historic property in the APE;
- Revised Section 3.2.3 "Environmental Consequences" to include FHWA's final project effect finding and the individual effect findings for each historic property listed in or eligible for inclusion in the NRHP;
- Deleted Section 3.2.4 "Measures to Minimize Harm and Mitigation"; and
- Updated Appendix E to include the *Section 106 Effects Assessment Report*, the April 11, 2017 consulting parties meeting materials, and correspondence regarding the project's effects from the SHPO and consulting parties.

This section discusses the presence of and potential impacts to cultural resources, which include historic and archaeological resources, within the Area of Potential Effects (APE) for the Project Corridor (APE defined in Section 3.2.2.1 below).

Because FHWA may provide funding for the proposed project, the project is considered a federal undertaking and is subject to compliance with the National Historic Preservation Act (NHPA) of 1966, as amended (54 USC 300101 *et seq.),* and its implementing regulations (36 CFR Part 800). Specifically, Section 106 of the NHPA requires federal agencies to take into account the effects of their undertakings on historic properties and to afford the Advisory Council on Historic Preservation (ACHP) a reasonable opportunity to comment. Historic properties are defined in 36 CFR 800.16(l)(1) as "any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in the National Register of Historic Places (NRHP)." The Section 106 evaluation process requires consultation and coordination with specific parties that have a demonstrated interest in historic properties in the project vicinity. These parties include the Illinois State Historic Preservation Officer (SHPO), local governments, and the public, and may involve tribal governments and parties with expertise regarding local historic properties. The ACHP and other federal agencies, if appropriate, may also be involved in the consultation process.

When a National Historic Landmark (NHL) is located within the APE and would be adversely affected by a project, the federal agency must also comply with Section 110(f) of the NHPA. Section 110(f) requires the agency undertake, to the maximum extent possible, planning and actions to minimize harm to any adversely affected NHL and

afford the ACHP an opportunity to comment. The ACHP regulations require that the National Park Service (NPS), an agency of the US Department of the Interior, be notified and invited to participate in the consultation involving NHLs.

Section 4(f) of the US Department of Transportation Act of 1966 also applies to historic properties and is discussed separately in Section 3.12, Special Lands.

3.2.1 Consultation

Per the process outlined in the Section 106 implementing regulations, FHWA, in cooperation with IDOT, identified organizations with an interest in cultural resources in the project vicinity and invited them to participate as consulting parties during the study process. These included the SHPO/Illinois Historic Preservation Agency (IHPA), representatives of municipal and county governments, and cultural resources and historic preservation organizations. Consulting party invitation letters were sent to 24 agencies and organizations; of that, nine accepted consulting party status, including the Chicago Department of Transportation, City of Chicago Historic Preservation District/Commission on Chicago Landmarks, DuPage County, Friends of the Parks, Historical Society of Oak Park and River Forest, Oak Park Conservatory – Park District of Oak Park, Oak Park Township, Village of Hillside, and Village of Oak Park. FHWA also identified federally recognized American Indian tribes with potential interests in the APE. FHWA sought to initiate government-to-government consultation to identify the tribes' interests in the proposed project and to participate as consulting parties in the Section 106 process. Consulting party invitation letters were sent to eight tribal governments. A list of consulting parties and tribal governments who received the consulting parties' invitation letter, their response status, and copies of the respective letters of invitation are included in Appendix E.

Consulting parties can provide comments on eligibility, effects, and mitigation as part of the Section 106 process. Public involvement in the Section 106 process is achieved through the public involvement procedures under the National Environmental Policy Act (NEPA) and separate Section 106 consulting parties meetings. Comments received on the Section 106 process after distribution of the DEIS are addressed in the Final Environmental Impact Statement (FEIS). Consulting parties' correspondence and meeting materials are included in Appendix E.

3.2.1.1 Columbus Park Consultation

Columbus Park, located on the north side of the I-290 right-of-way between Austin Boulevard and Central Avenue in the City of Chicago, was listed in the NRHP on May 20, 1991, and designated an NHL on July 31, 2003. It is considered nationally significant as the masterpiece of noted landscape architect Jens Jensen, reflecting the mature expression of his Prairie-style philosophies in landscape architecture and programming components. The park was mostly completed by 1920 and originally bound by Lexington Avenue to the south. In 1953, the park's southernmost 9 acres were taken for construction of the I-290 Eisenhower Expressway. The two ridges at the park's south end, which were originally created by Jensen to provide a sense of enclosure at the south end of the park, were not affected by the expressway construction, but the original golf

course configuration, softball and baseball fields, and gymnasium building were modified or moved. In the mid-1990s, a bike path was added along the golf course's south end to replicate the park's original circuit drive at the south perimeter.

At the request of the Chicago Park District, specific consideration was given to enhancing bicycle and pedestrian access along Columbus Park's southern boundary between Austin Boulevard and Central Avenue north of I-290 where no connectivity currently exists. This access would connect the proposed shared-use path from DesPlaines Avenue east to Austin Boulevard (proposed as part of each build alternative) with the existing path in the park as described above. Completing this section of the path would then provide continuous nonmotorized access between DesPlaines Avenue and Central Avenue.

In correspondence received October 15, 2015, the Chicago Park District concluded that this proposed improvement, along with other landscape enhancements, would not adversely affect the park and would provide additional opportunities to contribute to the park's historic integrity. Coordination is ongoing with the Park District and SHPO on the specific design elements of the proposed improvements, with consultation expected to continue into the project's design phase, focusing along the south boundary of Columbus Park. At this location, the Park District would donate at the west end a temporary easement for construction of a short section of paved shared-use path needed to connect the proposed multi-use path at Austin Boulevard to the existing park path. Grading, drainage, and select tree plantings are also proposed.

Enhancements are further proposed at the east end to include landscape improvements, such as low earthen berms, drainage improvements, and tree plantings. All of these features would be located within the park along the south boundary, adjacent to the existing I-290 right-of-way in locations to be prescribed and approved by the Park District and SHPO. There are no right-of-way needs from Columbus Park for the proposed I-290 improvements. A discussion of the Section 4(f) implications of these proposed improvements is in Section 3.12, Special Lands.

3.2.1.2 SHPO Meeting and Field Review

On March 30, 2016, FHWA and IDOT held a meeting and field review of the Project Corridor for federal and state agency representatives. Attendees included FHWA, US Environmental Protection Agency (USEPA), SHPO, IDOT Bureau of Design and Environment (IDOT-BDE), IDOT District 1, and the project team. The purpose of the meeting was to provide a briefing on the status of the study and design development and to review corridor field conditions focusing on Section 106 properties and EJ communities along the Project Corridor. The field visit included stops at many of the historic properties evaluated in the *Section 106 Historic Properties Identification Report* (March 2016). SHPO staff provided informal comments on the NRHP eligibility of select properties, potential additional properties to be evaluated, and potential project effects to historic properties.

3.2.1.3 August 11, 2016 Consulting Parties Meeting

On August 11, 2016, the project team held a meeting with the Section 106 consulting parties to discuss the identification and evaluation of historic properties for the I-290 Study, as discussed in the *Section 106 Historic Properties Identification Report* (March 2016) and *Section 106 Historic Properties Identification Addendum Report* (May 2016). The project team provided an overview of the Project Corridor and schedule, the Preferred Alternative, and the Section 106 review process and the role of consulting parties in that process. An overview of the identification and evaluation of historic properties and the proposed effects assessment methodology was also provided. Consulting parties' comments and discussion focused on the NRHP eligibility recommendations of individual properties contained in the reports, the process for delineating the APE, and potential effects to historic properties from proposed improvements, including noise walls.

3.2.1.4 April 11, 2017 Consulting Parties Meeting

On April 11, 2017, the project team held a meeting with the Section 106 consulting parties to discuss the assessment of effects to historic properties for the I-290 Project, as documented in the *Section 106 Effects Assessment Report* (April 2017). The project team provided an overview of the I-290 study and Preferred Alternative, a summary of the Section 106 review process, and an overview of the identification and evaluation of historic properties effort. The project team reviewed the effects assessment methodology and presented the effect finding for each NRHP-listed and NRHP-eligible historic property in the APE.

3.2.2 Affected Environment

3.2.2.1 Area of Potential Effects

The APE is defined in 36 CFR 800.16 as "the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties if any such properties exist. The APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking."

The APE for the project has been defined to include the I-290 interstate right-of-way, cross streets and railroad crossings with planned improvements, and at least one tax parcel adjacent to the interstate and those cross streets. In some areas, the APE extends greater than one tax parcel to account for vacant parcels and viewshed considerations. The APE boundary and description were submitted to the SHPO for review on December 18, 2015. The SHPO concurred with the APE boundary in a letter dated February 5, 2016. See Appendix E for the APE map set and methodology.

3.2.2.2 Identification of Historic Resources

Within the APE, architectural historians conducted an intensive-level survey of the resources 50 years of age or older that were previously identified by IDOT-BDE cultural resources staff as potentially eligible for inclusion in the NRHP. NRHP-listed properties were also photographed to document their status at the time of review. Additional research was conducted and the NRHP criteria were applied to evaluate the NRHP

eligibility of each identified resource. The individual determinations of NRHP eligibility are documented in the *Section 106 Historic Properties Identification Report* (March 2016) and the *Section 106 Historic Properties Identification Addendum Report* (May 2016) in Appendix E.

Within the APE, there is one NHL property, five NRHP-listed resources, and one historic district pending official NRHP designation. There are also two historic properties, including one district, that were previously determined eligible for inclusion in the NRHP within the APE. Table 3-23 provides a list of the nine NRHP-listed and previously determined NRHP-eligible properties within the APE.

Table 3-23. NRHP-Listed and Previously Determined NRHP-Eligible Historic Properties in the APE

Name	Address	NRHP Status	NRHP Criteria[1]	Effect Determination	Map Set Sheet No.[2]
Hulbert Historic District	Roughly bounded by Madison and Harrison streets, Clinton and South Kenilworth avenues, Oak Park	Previously Determined Eligible[3]	Eligible under Criteria A and C for community planning and subdivision development by Thomas Henry Hulbert, and for its collection of early twentieth-century Queen Anne-style homes and American Foursquare homes with Craftsman and Prairie-style influences.	No adverse effect: no direct impact to resource or adverse effect to integrity	7
Oak Park Conservatory	615 Garfield Street, Oak Park	Listed	Listed under Criteria A and C for association with the park movement in Oak Park as a locally significant example of glass and steel greenhouse design and as a significant example of greenhouse design in Illinois.	No adverse effect: no direct impact to resource or adverse effect to integrity	8

Table 3-23. NRHP-Listed and Previously Determined NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria[1]	Effect Determination	Map Set Sheet No.[2]
Paulina Mansions	901-927 Wesley Avenue and 701-711 Garfield Street, Oak Park	Previously Determined Eligible	Eligible under Criterion C as an example of early twentieth-century Tudor Revival-style, S-shaped courtyard apartment building in Oak Park.	No effect	8
Gunderson Historic District	Roughly bounded by Madison Street, Harrison Street, Gunderson Street, and South Ridgeland Avenue, Oak Park	Listed	Listed under Criteria A and C for association with community planning and subdivision development efforts undertaken by S.T. Gunderson and Sons firm, and for its uniformly designed collection of early twentieth-century American Foursquare homes with Colonial Revival, Craftsman, and Prairie-style influences.	No adverse effect: no direct impact to resource or adverse effect to integrity	8

Table 3-23. NRHP-Listed and Previously Determined NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria[1]	Effect Determination	Map Set Sheet No.[2]
Columbus Park	500 South Central Avenue, Chicago	National Historic Landmark	Listed under Criteria A and C for association with social and recreational history, and as the masterpiece of Jens Jensen, reflecting the mature expression of his Prairie-style philosophies in landscape architecture and programming components. Also meets NHL Criteria 4 as an exceptionally important work of design.	No adverse effect: project activity proposed within NHL boundary, but those improvements would have no adverse effect to integrity	9
Garfield Park	100 North Central Park Avenue, Chicago	Listed	Listed under Criteria A and C for association as one of three original parks of the West Park Commission that continually accommodated changing recreational and cultural needs of community, and for its significant landscape design and architectural history by William Le Baron Jenney, Oscar F. Dubuis, and Jens Jensen.	No adverse effect: no direct impact to resource or adverse effect to integrity	12

Table 3-23. NRHP-Listed and Previously Determined NRHP-Eligible Historic Properties in the APE (continued)

The Chicago Park Boulevard System Historic District	Approximately 26 miles of parks and boulevards from the southeast part of Chicago at Dr. Martin Luther King, Jr. Drive, west, north, and back east, to the eastern end of Logan Boulevard. The system consists of eight parks, 19 boulevards, and six squares, Chicago.	Pending Official Designation	Eligible under Criteria A and C for association with community planning and development as the first major comprehensive designed system in the country and creation of Chicago's neighborhoods in the late nineteenth century. Also for its examples of high-quality late nineteenth- and early twentieth-century architecture along the boulevards and associated parks.	No adverse effect: no direct impact to resource or adverse effect to integrity	12
Tri-Taylor Historic District	Roughly and irregularly bounded by Oakley, Harrison, and Claremont streets on the north and Taylor and Oakley streets on the southeast, Chicago	Listed	Listed under Criteria A and C for association with immigrant-developed neighborhoods on the Near West Side after the 1871 Chicago Fire, and its late nineteenth- and early twentieth-century residential urban architecture.	No adverse effect: no direct impact to resource or adverse effect to integrity	14

Table 3-23. NRHP-Listed and Previously Determined NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria[1]	Effect Determination	Map Set Sheet No.[2]
Cook County Hospital Administration Building	1835 West Harrison Street, Chicago	Listed	Listed under Criteria A and C as a Beaux Arts-style hospital administration building associated with the history of medicine, medical education, and public health in Chicago and nationwide.	No effect	15

[1] The NRHP Criteria for Evaluation are used to evaluate a property's historic significance. Properties may be NRHP-eligible under Criterion A for association with events that have made a significant contribution to the broad patterns of our history; under Criterion B for association with the lives of persons significant in our past; under Criterion C for embodying the distinctive characteristics of a type, period, or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction; or under Criterion D for having yielded, or being likely to yield, information important in prehistory or history.

[2] Refer to Section 3.0 Map Set for property locations.

[3] In a letter dated December 6, 2013, from the SHPO to the Village of Oak Park, the Hulbert Historic District was found to be eligible for listing in the NRHP by the SHPO. The SHPO's review of the district's eligibility was requested to support local historic district designation efforts of the district in Oak Park. On October 19, 2015, the Oak Park Village Board of Trustees rejected a proposal to designate the Hulbert Historic District as a local historic district and not to list the district in the NRHP.

As a result of the identification and evaluation efforts, 14 additional historic properties and no historic districts within the APE were determined eligible for inclusion in the NRHP. Table 3-24 provides a list of the NRHP-eligible properties within the APE. These findings were provided to the SHPO and Section 106 consulting parties for review and comment. The SHPO concurred with these findings in letters dated May 27, 2016, and September 22, 2016. See Appendix E for SHPO correspondence and consulting parties' comments.

Table 3-24. NRHP-Eligible Historic Properties in the APE

Name	Address	NRHP Status	NRHP Criteria	Effect Determination	Map Set Sheet No.[1]
Synagogue for Congregation B'Nai Israel of Proviso	10216 Kitchner Street, Westchester	Eligible	Eligible under Criterion C and Criteria Consideration A as a locally significant example of an Exaggerated Modern parabolic-shaped synagogue.	No effect	3
St. Eulalia Church	1851 South 9th Avenue, Maywood	Eligible	Eligible under Criterion C and Criteria Consideration A as an excellent example of Neo-Formalism applied to a religious building.	No adverse effect: no direct impact to resource or adverse effect to integrity	5
Park District of Forest Park	7441 Harrison Street, Forest Park	Eligible	Eligible under Criteria A and C for association with Works Progress Administration and recreation in Forest Park, and its original design form, features, and buildings.	No effect	6, 7
841 South Oak Park Avenue	841 South Oak Park Avenue, Oak Park	Eligible	Eligible under Criterion C as example of early twentieth-century Beaux Arts-style commercial building in Oak Park.	No adverse effect: no direct impact to resource or adverse effect to integrity	8
Suburban Trust and Savings Bank Building	840 South Oak Park Avenue, Oak Park	Eligible	Eligible under Criterion C as example of early twentieth-century Neoclassical-style bank building in Oak Park.	No adverse effect: no direct impact to resource or adverse effect to integrity	8

Table 3-24. NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria	Effect Determination	Map Set Sheet No.[1]
T.A. Holm Building	905 South Oak Park Avenue, Oak Park	Eligible	Eligible under Criteria A, B, and C for association with local success of T.A. Holm & Co. Realtors, productive life of T.A. Holm, and as example of early twentieth-century Classical and Art Deco-style, terra cotta-clad commercial building in Oak Park.	No effect	8
Maze Branch Library	845 Gunderson Avenue, Oak Park	Eligible	Eligible under Criteria A, B, and C for association with post-Depression and New Deal era neighborhood branch libraries construction, association with local librarian Adele H. Maze, and example of Revivalist library architecture by local architect Elmer C. Roberts in Oak Park.	No adverse effect: no direct impact to resource or adverse effect to integrity	8
Assumption Greek Orthodox Church	601 South Central Avenue, Chicago	Eligible	Eligible under Criterion C and Criteria Consideration A as a locally significant example of a Byzantine-style church with Romanesque style elements by local master architect Peter E. Camburas.	No adverse effect: no direct impact to resource or adverse effect to integrity	9

Table 3-24. NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria	Effect Determination	Map Set Sheet No.[1]
First Church of the Brethren	425 South Central Park Boulevard, Chicago	Eligible	Eligible under Criterion C and Criteria Consideration A as an excellent example of an expert interpretation of Tudor Revival architectural forms and ornament integrated into a religious building.	No adverse effect: no direct impact to resource or adverse effect to integrity	12
Altgeld Park Fieldhouse	515 South Washtenaw Avenue, Chicago	Eligible	Eligible under Criteria A and C for association with innovative early twentieth-century trends in recreation and as example of Classical Revival-style public building constructed for neighborhood park in Chicago.	No adverse effect: no direct impact to resource or adverse effect to integrity	13
Precious Blood Roman Catholic Church	2401 West Congress Parkway, Chicago	Eligible	Eligible under Criterion C and Criteria Considerations A and B as a remarkable and significant example of a purpose-built religious institution intended for worship and education. Collectively, two buildings convey significant design merit.	No adverse effect: no direct impact to resource or adverse effect to integrity	14

Table 3-24. NRHP-Eligible Historic Properties in the APE (continued)

Name	Address	NRHP Status	NRHP Criteria	Effect Determination	Map Set Sheet No.[1]
Crane Technical High School	2301 West Jackson Boulevard, Chicago	Eligible	Eligible under Criteria A and C for association with trend toward vocational schools in the early twentieth century in Chicago and as an example of Neoclassical-style school architecture.	No adverse effect: no direct impact to resource or adverse effect to integrity	14
Louis Pasteur Memorial	1800 West Harrison Street, Chicago	Eligible	Eligible under Criterion C and Criteria Considerations B and F as a locally significant and only known example of a freestanding Art Deco-style monument designed by prominent sculptor Leon Hermant in Chicago.	No effect	15
Chicago & Regional Midwest Joint Board Building	333 South Ashland Avenue, Chicago	Eligible	Eligible under Criteria A and C for association with critical growth of unions in 1920s Chicago and as example of Art Deco-style architecture designed by local architect Walter W. Ahlschlager in Chicago.	No effect	15

[1] Refer to Section 3.0 Map Set for property locations.

3.2.2.3 Identification of Archaeological Resources

The Illinois State Archaeological Survey (ISAS) completed a Phase I Survey Report and identified no previously recorded archaeological sites listed in the NRHP or that have been determined eligible for the NRHP in the proposed project limits of disturbance. No other potentially NRHP-eligible sites have been identified warranting further investigation. Therefore, no archaeological resources are considered present in the proposed project limits of disturbance. In a letter dated March 29, 2017, the SHPO concurred with the "No Archaeological Properties Affected" determination made by IDOT-BDE cultural resources staff. See Appendix E for SHPO and IDOT-BDE correspondence.

3.2.3 Environmental Consequences

3.2.3.1 Assessing Effects to Historic Properties

Effects assessments are based on the criteria of adverse effect as defined in 36 CFR 800.5, "Assessment of adverse effects." According to this portion of the Section 106 regulations, an adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the NHRP in a manner that would diminish the integrity of the property's location, design, materials, workmanship, feeling, or association. Examples of adverse effects include physical destruction of or damage to all or part of the property, alteration of a property not consistent with the Secretary's Standards for the Treatment of Historic Properties (36 CFR 68), change of the property's use or of the physical features within the property's setting that contribute to its historic significance, and introduction of visual, atmospheric, or audible elements that diminish the integrity of the property's significant historic features.

To determine if any historic properties would be affected by the project, project plans and documentation were reviewed for all NRHP-listed and eligible properties within the APE. Using the criteria of adverse effect established in 36 CFR 800.5(a)(1) and guidance found in *How to Apply the National Register Criteria for Evaluation* (US Department of the Interior, National Park Service, 1997), each historic property was evaluated to determine if implementation of the Preferred Alternative would alter any historically significant characteristics or features of each historic property by diminishing relevant aspects of that property's historic integrity.

For each historic property, a finding was made regarding the project's potential to affect its relevant aspect of integrity and character-defining features. The findings correspond to the guidelines set forth in 36 CFR Part 800 and supported by information on integrity in the National Register Bulletin *How to Apply the National Register Criteria for Evaluation*. If no aspect of integrity for an individual historic property is altered, the finding indicates that the historic property is not affected by the undertaking. If implementation of the project would alter one or more aspects of integrity for an individual historic property, but the effect would not alter a characteristic that qualifies that property for inclusion in the NRHP, then the finding for the property is "No Adverse Effect." If implementation of the project would alter a characteristic that qualifies a property for inclusion in the NRHP in a manner that diminishes the significant aspect(s) of integrity,

then the finding for the property would be "Adverse Effect." Indirect and cumulative effects to historic properties were also considered; such effects may include reasonably foreseeable land use changes.

Effects

No Build Alternative

No effects to historic properties are anticipated with the No Build Alternative because this alternative would not include modifications to existing infrastructure in the Project Corridor.

Preferred Alternative

Based on FHWA's Section 106 effects findings, the Preferred Alternative will have no effect or no adverse effect to built historic properties in the APE. The individual effects assessments for each built historic property are located in the Section 106 Effects Assessment Report (April 2017) in Appendix E. Table 3-23 and Table 3-24 summarize the proposed project's effects to each historic property.

No direct physical impacts to 22 of the 23 historic properties would occur with the Preferred Alternative because the proposed improvements generally fit within existing right-of-way and would not occur within their NRHP boundaries. New right-of-way is only required in smaller amounts and in areas farther away from historic properties. Project activity is proposed within the NHL boundary of Columbus Park because of temporary easements required for the shared-use path extension and landscape improvements in the park; however, these proposed improvements and the temporary easement would have no adverse effect to its integrity of location, design, materials, and workmanship.

No indirect effects to historic properties would occur as a result of the Preferred Alternative. The evaluation of indirect effects to historic properties considered changes in traffic noise and the introduction of new visual project components in their vicinity. This included an assessment of the degree to which traffic noise and visual project components, such as approved noise barriers, may diminish each historic properties' integrity of setting, feeling, and/or association and alter the characteristics qualifying it for inclusion in the NRHP.

Within the APE, the Preferred Alternative would result in six no effect findings and 17 no adverse effect findings. Therefore, FHWA made an effect determination that the I-290 Project would have no adverse effect to built historic properties. These findings were provided to the SHPO and Section 106 consulting parties for review and comment. Written comments were received from the Park District of Oak Park regarding vibration-related impacts during construction. The SHPO concurred with the no adverse effect finding in a letter dated May 25, 2017. See Appendix E for SHPO correspondence and consulting party comments.

3.2.3.2 Impacts to Archaeological Resources

There are no archaeological sites located in the proposed project limits of disturbance; therefore, there are no effects to archaeological resources.

3.3 Air Quality

Since the publication of the DEIS, the following substantive change to this section has been made:

- Updated Section 3.3.1.7 to reflect the most recent conformity analysis performed by CMAP.

The air quality analysis evaluates the potential air quality impacts of the proposed project. This includes an analysis of the proposed project's regional air quality levels; the project's impact on greenhouse gases (GHGs); the mobile source air toxic (MSAT) emissions of the project; whether the project will cause or contribute to a new localized exceedance of carbon monoxide (CO) ambient air quality standards or increase the frequency or severity of any existing exceedance; and the construction emissions associated with the project.

According to this analysis, the build alternatives would have minimal effects on regional criteria pollutant burdens, with changes of less than 1 percent compared to the No Build Alternative. The HOV 2+ Lane Alternative (HOV 2+), HOT 3+ Lane Alternative (HOT 3+), and HOT 3+ Lane and Toll Alternative (HOT 3+ & TOLL) show a slight decrease in all regional criteria pollutants, while the General Purpose Lane Alternative (GP Lane) has a mixed effect on regional criteria pollutants compared to the No Build Alternative. The build alternatives also would have minimal effects on GHG emission burdens, with changes of less than a quarter of 1 percent compared to the No Build Alternative. The GP Lane and HOV 2+ Alternatives show slight increases in GHG emissions, whereas the HOT 3+ and HOT 3+ & TOLL Alternatives show slight decreases in GHG emissions compared to the No Build Alternative. The build alternatives also would have minimal effects on MSAT, with changes of 1 percent or less compared to the No Build Alternative. The build alternatives show a slight decrease in most MSAT, except for benzene and diesel particulate matter (PM), compared to the No Build Alternative. The proposed project is not predicted to cause or exacerbate a violation of the applicable National Ambient Air Quality Standards (NAAQS) with regards to CO.

In 2012, USEPA strengthened the annual fine particle standard to 12 micrograms per cubic meter ($\mu g/m^3$). Due to insufficient quality assured monitoring data to assess compliance with the 2012 annual fine particle standard, USEPA designated the entire State of Illinois (including Cook County where the project is located) as unclassifiable for the 2012 annual $PM_{2.5}$ NAAQS.[31] The unclassified designation requires additional monitoring data, resulting in a deferred designation. A microscale $PM_{2.5}$ analysis for the project only is performed if it is located in a designated nonattainment or maintenance area. Although Cook County was designated a maintenance area for the 1997 annual $PM_{2.5}$ NAAQS, that standard was revoked effective October 24, 2016.[32] As such, after the effective date of the revocation, areas that have been redesignated to attainment for the

[31] https://www.epa.gov/particle-pollution-designations.

[32] https://www.gpo.gov/fdsys/pkg/FR-2016-08-24/pdf/2016-18768.pdf.

1997 annual $PM_{2.5}$ NAAQS (i.e., maintenance areas for the 1997 annual $PM_{2.5}$ NAAQS such as Cook County) will not be required to make transportation conformity determinations for the 1997 annual $PM_{2.5}$ NAAQS.

Construction-related air quality impacts would be temporary in nature and would be mitigated in accordance with IDOT's provisions on dust control.

3.3.1 Affected Environment

"Air Pollution" is a general term that refers to one or more chemical substances that degrade the quality of the atmosphere. Individual air pollutants degrade the atmosphere by reducing visibility, damaging property, reducing the productivity or vigor of crops or natural vegetation, and/or reducing human or animal health. Air quality is a term used to describe the amount of air pollution the public is exposed to in the environment.

3.3.1.1 US Environmental Protection Agency

USEPA is responsible for establishing the NAAQS and enforcing the Clean Air Act (CAA), and regulates emission sources, such as aircraft, ships, and certain types of locomotives, under the exclusive authority of the federal government. The USEPA also has jurisdiction over emission sources outside state waters (e.g., beyond the outer continental shelf) and establishes various emission standards. For additional information about the USEPA, the reader can contact its general Internet address found at http://www.epa.gov. Additional information on the activities of USEPA regarding transportation and air quality can be found at http://www.epa.gov/otaq/index.htm.

3.3.1.2 Clean Air Act Amendments of 1990

The Clean Air Act Amendments of 1990 (CAAA) direct the USEPA to implement environmental policies and regulations that will ensure acceptable levels of air quality. Under the CAAA, a project cannot:

- Cause or contribute to any new violation of any NAAQS in any area;
- Increase the frequency or severity of any existing violation of any NAAQS in any area; or
- Delay timely attainment of any NAAQS or any required interim emission reductions or other milestones in any area.

3.3.1.3 National Ambient Air Quality Standards

As required by the CAA, NAAQS have been established for six major air pollutants. These pollutants are: carbon monoxide (CO), nitrogen dioxide (NO_2), ozone (O_3), particulate matter (PM_{10} and $PM_{2.5}$), sulfur dioxide (SO_2), and lead (Pb). These standards are summarized in Table 3-25. The "primary" standards have been established to protect the public health. The "secondary" standards are intended to protect the nation's welfare and account for air pollutant effects on soil, water, visibility, materials, vegetation, and other aspects of the general welfare. The State of Illinois has adopted these standards as the state standards.

Table 3-25. National Ambient Air Quality Standards

Pollutant		Primary/ Secondary	Averaging Time	Level	Form
Carbon Monoxide (CO)		Primary	8-hour	9 ppm	Not to be exceeded more than once per year
			1-hour	35 ppm	
Lead (Pb)		Primary and secondary	Rolling 3-month average	0.15 µg/m³ (1)	Not to be exceeded
Nitrogen Dioxide (NO_2)		Primary	1-hour	100 ppb	98th percentile, averaged over 3 years
		Primary and secondary	Annual	53 ppb (2)	Annual mean
Ozone (O_3)		Primary and secondary	8-hour	0.070 ppm (3)	Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years
Particle Matter	$PM_{2.5}$	Primary	Annual	12 µg/m³	Annual mean, averaged over 3 years
		Secondary	Annual	15 µg/m³	Annual mean, averaged over 3 years
		Primary and secondary	24-hour	35 µg/m³	98th percentile, averaged over 3 years
	PM_{10}	Primary and secondary	24-hour	150 µg/m³	Not to be exceeded more than once per year on average over 3 years
Sulfur Dioxide (SO_2)		Primary	1-hour	75 ppb (4)	99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
		Secondary	3-hour	0.5 ppm	Not to be exceeded more than once per year

Source: USEPA Office of Air and Radiation, https://www.epa.gov/criteria-air-pollutants/naaqs-table.

(1) In areas designated nonattainment for the Pb standards prior to the promulgation of the current (2008) standards, and for which implementation plans to attain or maintain the current (2008) standards have not been submitted and approved, the previous standards (1.5 µg/m³ as a calendar quarter average) also remain in effect.

(2) The level of the annual NO_2 standard is 0.053 parts per million (ppm). It is shown here in terms of parts per billion (ppb) for the purposes of clearer comparison to the 1-hour standard level.

(3) Final rule signed October 1, 2015, and effective December 28, 2015. The previous (2008) O_3 standards additionally remain in effect in some areas. Revocation of the previous (2008) O_3 standards and transitioning to the current (2015) standards will be addressed in the implementation rule for the current standards.

(4) The previous SO_2 standards (0.14 ppm 24-hour and 0.03 ppm annual) will additionally remain in effect in certain areas: (1) any area for which it is not yet 1 year since the effective date of designation under the current (2010) standards, and (2) any area for which implementation plans providing for attainment of the current (2010) standard have not been submitted and approved and which is designated nonattainment under the previous SO_2 standards or is not meeting the requirements of a State Implementation Plan (SIP) call under the previous SO_2 standards (40 CFR 50.4(3)). A SIP call is an USEPA action requiring a state to resubmit all or part of its SIP to demonstrate attainment of the required NAAQS.

3.3.1.4 Ambient Air Quality Data

Local Meteorology

The proposed project is located in Cook County and extends approximately 13 miles centered along I-290 from the I-88 and I-290 split on the west to Racine Avenue on the east. The corridor passes through eight communities: Chicago, Bellwood, Broadview, Forest Park, Hillside, Maywood, Oak Park, and Westchester.

The climate is predominantly continental, ranging from relatively warm in the summer to relatively cold in the winter; however, the continental location is partially modified by Lake Michigan and to a lesser extent by the other Great Lakes.

In late autumn and winter, air masses that are initially very cold often reach the region only after being tempered by passage over one or more of the Great Lakes. Similarly, in late spring and summer, air masses reaching the city from the north, northeast, or east are cooler because of movement over the Great Lakes. Very low winter temperatures most often occur in the air that flows southward to the west of Lake Superior before reaching the area. In summer, the higher temperatures are with south or southwest flow and are therefore not influenced by the lakes. Temperatures of 96 degrees Fahrenheit (°F) or higher occur in about half of the summers, while about half of the winters have a minimum of as low as -15 °F.

Precipitation falls mostly from air that has passed over the Gulf of Mexico. But in winter there can be snowfall, with Lake Michigan as the principal moisture source. The effect of Lake Michigan, both on winter temperatures and lake-produced snowfall, is enhanced by non-freezing of much of the lake during the winter. Summer thunderstorms are often locally heavy and variable. Longer periods of continuous precipitation are mostly in autumn, winter, and spring. Approximately half of the precipitation in the winter, and approximately 10 percent of the annual total precipitation, falls as snow. Snowfall from month to month and year to year is greatly variable.

Local Monitored Air Quality

The monitored information for the monitoring stations near the proposed project is presented in Table 3-26. This table presents the last 3 years of available monitor data (2013-2015) at each of these stations to illustrate the Study Area's general air quality trends. Additional air quality information for the Study Area for Illinois can be found at http://www.idot.illinois.gov/transportation-system/environment/index.

NM = Not measured.

3.3.1.5 Attainment Status

Section 107 of the 1977 CAAA requires that the USEPA publish a list of all geographic areas in compliance with the NAAQS, plus those not attaining the NAAQS. Areas not in NAAQS compliance are deemed nonattainment areas. Areas that have insufficient data to make a determination are deemed unclassified and are treated as being attainment areas until proven otherwise. Maintenance areas are areas that were previously designated as nonattainment for a particular pollutant but have since demonstrated compliance with the NAAQS for that pollutant. An area's designation is based on the data collected by the state monitoring network on a pollutant-by-pollutant basis.

The proposed project is located in Cook County in Illinois. Table 3-27 shows the current attainment status for the portion of Cook County in which the proposed project is located. As shown in the table, the USEPA has classified the portion of Cook County in which the proposed project is located as a nonattainment area for O_3 and has designated the entire state as unclassifiable for the 2012 annual $PM_{2.5}$ NAAQS.[33] The unclassifiable designation is due to monitoring data validity issues, resulting in deferred designation.

Table 3-27. Project Area Attainment Status

Pollutant	Status
Ozone (O_3)	Nonattainment
Nitrogen Dioxide (NO_2)	Attainment
Carbon Monoxide (CO)	Attainment
Particulate Matter (PM_{10})	Attainment
2012 Particulate Matter ($PM_{2.5}$) Annual/2006 24-Hour	Unclassifiable/ Attainment
Lead (Pb)	Attainment

Source: USEPA, 2016: https://www.epa.gov/green-book.

3.3.1.6 Air Quality Index

The Air Quality Index (AQI) is the current national standard method for reporting air pollution levels to the general public. The AQI is based on the short-term federal NAAQS, the federal episode criteria, and the federal Significant Harm levels for five of the "criteria pollutants," namely, ground-level O_3, SO_2, CO, PM, and NO_2. The AQI levels have been divided into six categories: Good (0-50), Moderate (51-100), Unhealthy for Sensitive Groups (101-150), Unhealthy (151-200), Very Unhealthy (201-300), and Hazardous (301-500).

[33] https://www.epa.gov/particle-pollution-designations.

The AQI classification of "Unhealthy for Sensitive Groups" occurs on occasion in Illinois under the 8-hour O_3 and $PM_{2.5}$ standards. AQI classifications of Unhealthy are uncommon, and classifications of Very Unhealthy are rare in the state. To date, no classifications of Hazardous air quality have occurred in Illinois.

3.3.1.7 Transportation Conformity Rule, State Implementation Plan, and Transportation Improvement Program Status

Under the CAAA of 1990, the Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA), and subsequent reauthorizations, proposed transportation projects must be derived from an MTP that conforms with the state air quality plans as outlined in the State Implementation Plan (SIP). The SIP sets forth the state's strategies for achieving air quality standards. USEPA's Transportation Conformity Rule requires federal agencies to conduct a conformity determination for a proposed transportation plan, program, or project in a nonattainment or maintenance area before it can be approved, accepted, funded, or adopted. A conformity determination is a formal regulatory process by which the agency evaluates, analyzes, and determines whether the proposed federal action would comply with the air quality standards under the CAA. Specifically, transportation plans, programs, or projects may not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions towards attainment.

The conformity rule also establishes the process by which FHWA, the Federal Transit Administration (FTA), and local MPOs determine conformance of MTPs and TIPs, and federally funded highway and transit projects. As part of this process, local MPOs are required under regulations promulgated in the CAA of 1990 to determine conformance of MTPs and TIPs before they are adopted, approved, or accepted. TIPs are a subset of staged, multi-year, intermodal programs of transportation projects covering metropolitan planning areas that are consistent with MTPs. The TIPs include a list of financially constrained roadway, transit, and nonmotorized transportation projects for implementation by cities, counties, transit agencies, and other local jurisdictions. Projects to be completed in the near term are included in the region's TIP. The Statewide Transportation Improvement Program (STIP) includes the TIP projects for the entire state.

The purpose of the air quality analysis is to develop MTPs and TIPs that conform to state or federal air quality implementation plans. FHWA and FTA must make conformity determinations on federally funded projects before they are adopted, accepted, approved, or funded.

The NAAQS, established by the USEPA, set maximum allowable concentration limits for six criteria air pollutants. Areas in which air pollution levels persistently exceed the NAAQS may be designated as "nonattainment." States where a nonattainment area is located must develop and implement an SIP containing policies and regulations that will bring about attainment of the NAAQS.

Areas that had been designated as nonattainment, but that have attained the NAAQS for the criteria pollutant(s) associated with the nonattainment designation, will be designated as maintenance areas.

All areas of Illinois currently are in attainment of the standards for four of the six criteria pollutants: CO, NO_2, SO_2, and Pb.

For the 8-hour O_3 standards, Cook, DuPage, Kane, Lake, McHenry, and Will counties, as well as Aux Sable and Goose Lake townships in Grundy County and Oswego Township in Kendall County, have been designated as nonattainment areas for O_3. Jersey, Madison, Monroe, and St. Clair counties in the St. Louis area also have been designated as moderate nonattainment areas for the 8-hour ozone standard. The Lake Calumet area and Lyons Township in Cook County have been designated as a maintenance area for the particulate matter (PM_{10}) standard. In addition, Oglesby and several adjacent townships in LaSalle County and Granite City Township and Nameoki Township in Madison County have been designated as maintenance areas for the PM_{10} standard. All other areas of Illinois currently are in attainment for the O_3 and PM_{10} standards. The entire state is designated unclassifiable for $PM_{2.5}$.

This project is entirely located within an area designated as nonattainment for the O_3 standard and unclassifiable for the $PM_{2.5}$ standard of the NAAQS.

This project is included in the Fiscal Year (FY) 2014 – 2019 TIP and MTP endorsed by the MPO Policy Committee. Projects in the TIP are considered to be consistent with the MTP. The project is within the fiscally constrained portion of the MTP.

Following the June 8, 2017 approval by the MPO Policy Committee,[34], FHWA and FTA determined that the 2040 Regional Transportation Plan and TIP conform with the SIP and the transportation-related requirements of the 1990 CAAA. These findings were in accordance with 40 CFR Part 93, "Determining Conformity of Federal Actions to State or Federal Implementation Plans." The project's design concept and scope are consistent with the project information used for the TIP conformity analysis; therefore, this project conforms to the existing SIP and the transportation-related requirements of the 1990 CAAA.

The TIP number for this project is ID #04-00-0023.[35]

3.3.1.8 Relevant Pollutants for Analysis

Pollutants that can be traced principally to motor vehicles are relevant to the evaluation of the proposed project's impacts. These pollutants include CO, hydrocarbons (HC),

[34] http://www.cmap.illinois.gov/documents/10180/654518/PolicyCmteMemo--SpecialConformity06-01-2017.pdf/e8ea35a6-8444-4c18-9686-c06b911290d5

[35] https://etip.cmap.illinois.gov/project_info?project_id=34472&version=3&view_type=&fromPage=order%5Fby%3D%26order%5Forder%3D%26order%5Fold%5Fby%3D%26search%5Fstr%3D04%2D00%2D0023%26IS%5FFROM%5FFULL%3DTrue%26get%5Ftop%5Frows%3D100%26%5F%3D1495037369518%26end_page=

nitrogen oxides (NOx), O_3, PM_{10}, $PM_{2.5}$, and MSAT. Transportation sources account for a small percentage of regional emissions of sulfur oxides (SOx) and Pb; thus, a detailed analysis of these pollutants is not required.

HC (aka, volatile organic compounds or VOCs) and NOx emissions from automotive sources are a concern primarily because they are precursors in the formation of O_3 and PM. O_3 is formed through a series of reactions that occur in the atmosphere in the presence of sunlight. Because the reactions are slow and occur as the pollutants are diffusing downwind, elevated O_3 levels often are found many miles from the sources of the precursor pollutants; therefore, the effects of HC and NOx emissions generally are examined on a regional or "mesoscale" basis.

PM_{10} and $PM_{2.5}$ impacts are both regional and local. A large portion of PM, especially PM_{10}, comes from disturbed vacant land, construction activity, and paved road dust. $PM_{2.5}$ also comes from these sources. Motor vehicle exhaust, particularly from diesel vehicles, also is a source of PM_{10} and $PM_{2.5}$. PM_{10}, and especially $PM_{2.5}$, also can be created by secondary formation from precursor elements such as SO_2, NO_X, VOCs, and ammonia (NH_3). Secondary formation occurs because of chemical reaction in the atmosphere generally downwind some distance from the original emission source; thus, it is appropriate to predict concentrations of PM_{10} and $PM_{2.5}$.

CO impacts are generally localized. Even under the worst meteorological conditions and most congested traffic conditions, high concentrations are limited to a relatively short distance (300 to 600 feet) of heavily traveled roadways. Vehicle emissions are the major sources of CO. A screening analysis will be performed to determine if the project's traffic patterns warrant a microscale CO analysis.

GHG, which contributes to climate change, is a national and global concern. While the earth has gone through many natural climate variations in its history, there is general agreement that the earth's climate is currently changing at an accelerated rate and will continue to do so for the foreseeable future. Anthropogenic (human-caused) GHG emissions contribute to this rapid change. Carbon dioxide (CO_2) makes up the largest component of these GHG emissions. Other prominent transportation GHGs include methane (CH_4) and nitrous oxide (N_2O).

MSAT impacts are both regional and local. Through the issuance of USEPA's Final Rule (FR) regarding emission control of Hazardous Air Pollutants from Mobile Sources [66 FR 17229], it was determined that many existing and newly promulgated mobile source emission control programs would result in a reduction of MSATs. The USEPA examined the impacts of existing and newly promulgated mobile source control programs, including its reformulated gasoline program, its national low-emission vehicle standards, its Tier 2 motor vehicle emissions standards and gasoline sulfur control requirements, and its proposed heavy duty engine and vehicle standards and on-highway diesel fuel requirements. Future emissions likely would be lower than present levels as a result of the USEPA's national control programs that are projected to reduce MSAT emissions by 91 percent from 2010 to 2050, even if VMT increases by 45 percent.

3.3.2 Environmental Consequences

3.3.2.1 Emission Burden Analysis

A regional, or mesoscale, analysis of a project determines a project's overall impact on regional air quality levels. A regional analysis was performed for the proposed project using the version of USEPA's MOVES emissions program, MOVES2014. MOVES2014 incorporates project-generated VMT as well as specific MOVES input factors, such as inspection and maintenance programs, fleet mix, and speed profiles, for the traffic network being analyzed. MOVES input factors were obtained from CMAP.

The emission burden analysis of the proposed project determines the annual "pollutant burden" levels for each of the build alternatives, as well as the No Build Alternative, to provide a basis of comparison for regional emissions of each of the criteria pollutants under the different alternatives. The 2040 VMT and emission burdens (in tons) for each of the build alternatives, as well as the No Build Alternative, are presented in Table 3-28.

The GP Lane Alternative shows a slight increase in all regional criteria pollutants except for PM_{10}, for which it shows a slight decrease compared to the No Build Alternative. The HOV 2+, HOT 3+, and HOT 3+ & TOLL Alternatives show a slight decrease in all regional criteria pollutants compared to the No Build Alternative. All changes in regional pollutant burdens are minimal, with all pollutants showing less than a 1 percent change when comparing the build alternatives to the No Build Alternative in 2040.

3.3.2.2 GHG Analysis

A GHG analysis also was performed for the proposed project using the version of USEPA's MOVES air emissions program, MOVES2014. The GHG analysis of the proposed project determines the annual GHG emission burdens for each of the build alternatives, as well as the No Build Alternative, to provide a basis of comparison for emissions of GHGs under the different alternatives.

The Global Warming Potential (GWP) was developed to allow comparisons of the global warming impacts of different GHGs. Specifically, it is a measure of how much energy the emissions of 1 ton of a gas will absorb over a given period, relative to the emissions of 1 ton of CO_2. The larger the GWP, the more that a given gas warms the earth compared to CO_2 over that period. The period usually used for GWPs is 100 years. GWPs provide a common unit of measure, which allows analysts to add up emissions estimates of different gases (e.g., to compile a national GHG inventory) and allows policymakers to compare emissions reduction opportunities across sectors and gases. CO_2, by definition, has a GWP of 1; CH_4 has a GWP of 25; and N_2O has a GWP of 298.

The potential effects of GHGs are reported in CO_2 Equivalents (CO_2e), which is a combined measure of GHG emissions weighted according to the GWP of each gas, relative to CO_2. The 2040 VMT and GHG emission burdens (in tons of CO_2e) for each of the build alternatives, as well as the No Build Alternative, are presented in Table 3-29.

Table 3-28. 2040 Regional Emission Burdens (Annual)

Pollutant/ Parameter	Alternative

*Note: GHG emissions were adjusted by a factor of 1.27, as recommended by FHWA, to account for fuel cycle emissions.

The GP Lane and HOV 2+ Alternatives show slight increases in GHG emissions, whereas the HOT 3+ and HOT 3+ & TOLL Alternatives show slight decreases in GHG emissions compared to the No Build Alternative. All changes in GHG emissions are minimal, with less than a quarter of 1 percent change when comparing the build alternatives to the No Build Alternative in 2040.

Both the State of Illinois and the City of Chicago have GHG emission reduction targets in place. The State of Illinois aims to reduce GHG emissions to 1990 levels by the year 2020 and to 60 percent below 1990 levels by the year 2050.[36] The City of Chicago aims to reduce GHG emissions to 25 percent below 1990 levels by 2020 and to 80 percent below 1990 levels by 2050.[37] Both the HOT 3+ and HOT 3+ & TOLL Alternatives would be consistent with the State and City GHG reduction targets, as they both show slight decreases in GHG emissions compared to the No Build Alternative in 2040.

The GHG emissions from construction of the project were calculated using FHWA's Infrastructure Carbon Estimator (ICE), a spreadsheet tool that estimates GHG emissions from the construction of transportation facilities. ICE was used to analyze the GHG emissions from construction of the I-290 mainline over a 4-year timeframe. This was based on specific project inputs, including ADT of the facility, lane-miles of roadway widening and construction, and lane-miles of bridge widening and construction. The tool also estimates annual GHG emissions from the construction impacts on vehicle operations, which cause vehicle delay. The results are presented in Table 3-30. The total annual construction emissions represent approximately 0.04 percent of the annual GHG emissions presented in Table 3-29.

Table 3-30. Construction GHG Emissions (Annual)*

Construction Element	CO_2e (Tons)
Materials	2,499
Construction Equipment	1,194
Routine Maintenance	85
Operational Element	**CO_2e (Tons)**
Construction Impacts to Vehicle Delay	508
Annual Total	*4,268*

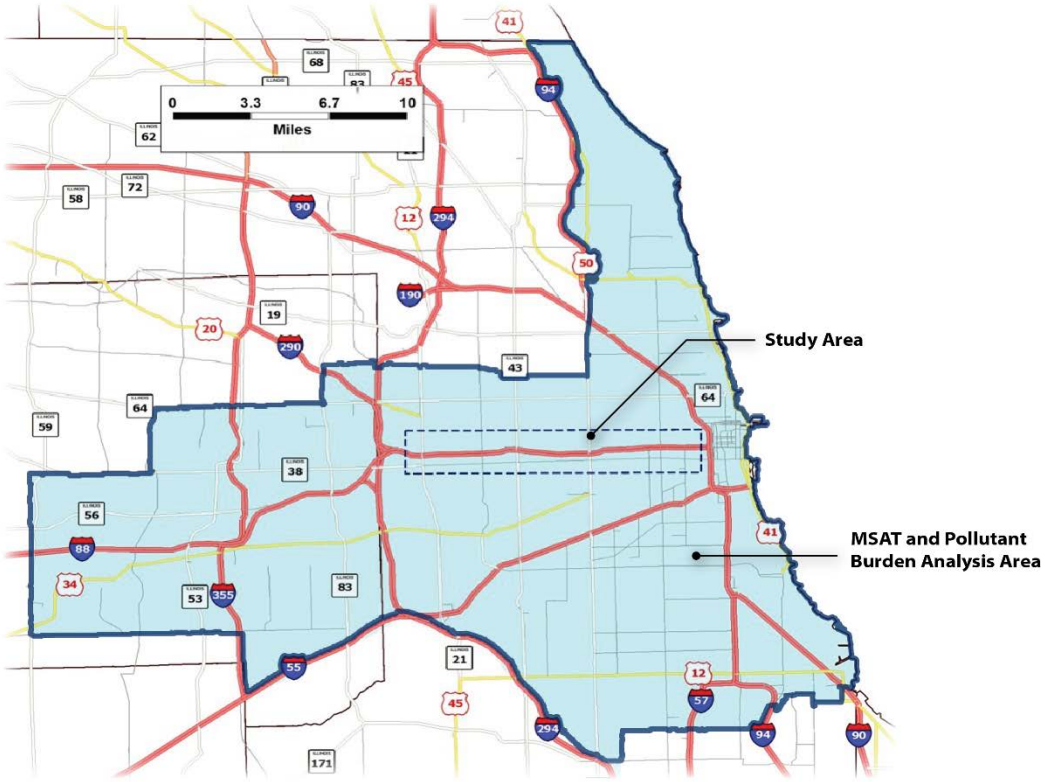
3.3.2.3 MSAT Analysis

USEPA also regulates air toxics. MSATs are a subset of the 188 air toxics defined by the CAA. The MSATs are compounds emitted from highway vehicles and non-road equipment. Some toxic compounds are present in fuel and are emitted to the air when the fuel evaporates or passes through the engine unburned. Other toxics are emitted from the incomplete combustion of fuels or as secondary combustion products. Metal air toxics result from engine wear or from impurities in oil or gasoline. FHWA's *Updated Interim Guidance on Mobile Source Air Toxics Analysis in NEPA* (October 2016)[38] suggests a tiered approach for addressing MSAT in NEPA documents.

A quantitative analysis provides a basis for identifying and comparing the potential differences among MSAT emissions, if any, between the alternatives. The quantitative assessment presented is derived in part from a study conducted by FHWA entitled *A Methodology for Evaluating Mobile Source Air Toxic Emissions among Transportation Project Alternatives* (FHWA, 2006). FHWA's Interim Guidance groups projects into the following tier categories:



- Tier 1 – No analysis for projects without potential for meaningful MSAT effects;
- Tier 2 – Qualitative analysis for projects with low potential MSAT effects; and
- Tier 3 – Quantitative analysis to differentiate alternatives for projects with higher-potential MSAT effects.

Based on FHWA's recommended tiering approach, the proposed project falls within the Tier 3 approach (i.e., for projects with a high potential for MSAT effects). In accordance with FHWA's recommendation, USEPA's MOVES2014 was used to calculate annual MSAT pollutant burdens for the build alternatives and the No Build Alternative.

The MSAT Analysis Area was refined to focus on the roadway links that are substantially impacted by the proposed project. Comparisons between the No Build Alternative and build alternatives were therefore made for links for an analysis area (Figure 3-53) where daily traffic volumes differ by 5 percent or more, or a change of 500 vehicles (ADT) or more per day.

[38] Available at https://www.fhwa.dot.gov/environment/air_quality/air_toxics/policy_and_guidance/msat/index.cfm.

Figure 3-53. MSAT Analysis Area

Source: WSP Parsons Brinckerhoff, 2015.

The results of the MSAT analysis are presented in Table 3-31. As shown in the table, the GP Lane Alternative shows a slight decrease in most MSAT except for benzene and diesel PM, which show a slight increase, compared to the No Build Alternative. The HOV 2+ and HOT 3+ Alternatives show a slight decrease in all MSAT compared to the No Build Alternative. The HOT 3+ & TOLL Alternative shows a slight decrease in all MSAT except for benzene, for which it shows a slight increase, compared to the No Build Alternative. Overall, changes in MSAT are minimal, with differences of 1 percent or less, when comparing the build alternatives to the No Build Alternative.

In summary, it is projected that there would be changes in MSAT emissions in the immediate area of the proposed project under the build alternatives, regardless of which one is chosen, relative to the No Build Alternative, as a result of the VMT changes associated with the project. The MSAT levels could be higher in some locations than others, such as adjacent to the proposed project, but current tools and science are not adequate to quantify them. Regardless, on a regional basis, USEPA's vehicle and fuel regulations, coupled with fleet turnover, will over time cause substantial reductions that, in almost all cases, will cause region-wide MSAT levels to be substantially lower than today.

Table 3-31. 2040 MSAT Emission Burdens (Annual)

Pollutant/ Parameter	Alternative								
	No Build (Tons)	GP Lane		HOV 2+		HOT 3+		HOT 3+ & TOLL

*Polycyclic organic matter emissions are not calculated by MOVES, but the trend would be similar to that for naphthalene.

This document has provided a quantitative analysis of MSAT emissions relative to the proposed project and has acknowledged that the build alternatives could increase exposure to MSAT emissions in certain locations, although the concentrations and duration of exposures are uncertain. Available technical tools do not enable prediction of the project-specific health impacts of the emission changes associated with the alternatives. Because of these limitations, the following discussion is included in accordance with the President's Council on Environmental Quality regulations (40 CFR, Section 1502.22[b]) regarding incomplete or unavailable information.

Information that is Unavailable or Incomplete

In FHWA's view, information is incomplete or unavailable to credibly predict the project-specific health impacts due to changes in MSAT emissions associated with a proposed set of highway alternatives. The outcome of such an assessment, adverse or not, would be influenced more by the uncertainty introduced into the process through assumption and speculation rather than any genuine insight into the actual health impacts directly attributable to MSAT exposure associated with a proposed action.

The USEPA is responsible for protecting the public health and welfare from any known or anticipated effect of an air pollutant. They are the lead authority for administering the CAA and its amendments and have specific statutory obligations with respect to hazardous air pollutants and MSAT. The USEPA is in the continual process of assessing human health effects, exposures, and risks posed by air pollutants. They maintain the Integrated Risk Information System, which is "a compilation of electronic reports on specific substances found in the environment and their potential to cause human health effects" (USEPA, http://www.epa.gov/iris/). Each report contains assessments of non-cancerous and cancerous effects for individual compounds and quantitative estimates of risk levels from lifetime oral and inhalation exposures, with uncertainty spanning perhaps an order of magnitude.

Other organizations also are active in the research and analyses of the human health effects of MSAT, including the Health Effects Institute (HEI). Two HEI studies are summarized in Appendix D of FHWA's *Updated Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents.* Among the adverse health effects linked to MSAT compounds at high exposures are cancer in humans in occupational settings; cancer in animals; and irritation to the respiratory tract, including the exacerbation of asthma. Less obvious is the adverse human health effects of MSAT compounds at current environmental concentrations (HEI Special Report 16, https://www.healtheffects.org/publication/mobile-source-air-toxics-critical-review-literature-exposure-and-health-effects) or in the future as vehicle emissions substantially decrease.

The methodologies for forecasting health impacts include emissions modeling, dispersion modeling, exposure modeling, and then final determination of health impacts, with each step in the process building on the model predictions obtained in the previous step. All are encumbered by technical shortcomings or uncertain science that prevents a more complete differentiation of the MSAT health impacts among a set of project alternatives. These difficulties are magnified for lifetime (i.e., 70 year)

assessments, particularly because unsupportable assumptions would have to be made regarding changes in travel patterns and vehicle technology (which affects emissions rates) over that time frame since such information is unavailable.

It is particularly difficult to reliably forecast 70-year lifetime MSAT concentrations and exposure near roadways; to determine the portion of time that people are actually exposed at a specific location; and to establish the extent attributable to a proposed action, especially given that some of the information needed is unavailable.

There are considerable uncertainties associated with the existing estimates of toxicity of the various MSAT, because of factors such as low-dose extrapolation and translation of occupational exposure data to the general population, a concern expressed by HEI (Special Report 16, https://www.healtheffects.org/publication/mobile-source-air-toxics-critical-review-literature-exposure-and-health-effects). As a result, there is no national consensus on air dose-response values assumed to protect the public health and welfare for MSAT compounds, and in particular for diesel PM. The USEPA states that with respect to diesel engine exhaust, "[t]he absence of adequate data to develop a sufficiently confident dose-response relationship from the epidemiologic studies has prevented the estimation of inhalation carcinogenic risk (USEPA IRIS database, Diesel Engine Exhaust, Section II.C. https://cfpub.epa.gov/ncea/iris/iris_documents/documents/subst/0642.htm#quainhal)."

There also is the lack of a national consensus on an acceptable level of risk. The current context is the process used by the USEPA as provided by the CAA to determine whether more stringent controls are required to provide an ample margin of safety to protect public health or to prevent an adverse environmental effect for industrial sources subject to the maximum achievable control technology standards, such as benzene emissions from refineries. The decision framework is a two-step process. The first step requires USEPA to determine an "acceptable" level of risk due to emissions from a source, which is generally no greater than approximately 100 in a million. Additional factors are considered in the second step, the goal of which is to maximize the number of people with risks less than one in a million due to emissions from a source. The results of this statutory two-step process do not guarantee that cancer risks from exposure to air toxics are less than one in a million; in some cases, the residual risk determination could result in maximum individual cancer risks that are as high as approximately 100 in a million. In a June 2008 decision, the US Court of Appeals for the District of Columbia Circuit upheld USEPA's approach to addressing risk in its two-step decision framework. Information is incomplete or unavailable to establish that even the largest of highway projects would result in levels of risk greater than deemed acceptable.

Because of the limitations in the methodologies for forecasting health impacts described, any predicted difference in health impacts between alternatives is likely to be much smaller than the uncertainties associated with predicting the impacts. Consequently, the results of such assessments would not be useful to decision makers, who would need to weigh this information against project benefits, such as reducing traffic congestion,

accident rates, and fatalities plus improved access for emergency response, that are better suited for quantitative analysis.

3.3.2.4 Microscale CO Analysis

In accordance with the Illinois Carbon Monoxide Screen for Intersection Modeling (COSIM) Air Quality Manual Version 4.0, the proposed project is exempt from a project-level CO analysis because the highest design-year approach volume on the busiest leg of each of the intersections analyzed is less than 5,000 vehicles per hour.

3.3.2.5 Microscale $PM_{2.5}$ Analysis

At the September 3, 2015, meeting of the Tier II Consultation Team, updated project information was presented (e.g., alternatives, traffic). Based on updated truck traffic information for the project, the Tier II Consultation Team said that the project is likely not to be considered a "Project of Air Quality Concern," because the project does not add a substantial amount of diesel truck traffic. Additionally, USEPA announced that due to insufficient quality assured monitoring data to assess compliance with the 2012 annual fine particle standard, the USEPA was designating the entire state of Illinois (including Cook County where the project is located) as unclassifiable for the 2012 annual $PM_{2.5}$ NAAQS. Furthermore, Cook County's designation as a maintenance area for the 1997 annual $PM_{2.5}$ NAAQS is no longer valid as of October 24, 2016, when the 1997 annual $PM_{2.5}$ NAAQS is revoked. As such, a transportation conformity determination for the 1997 annual $PM_{2.5}$ NAAQS is not required. A microscale $PM_{2.5}$ analysis was not performed for the above reasons.

3.3.3 Measures to Minimize Harm and Mitigation

3.3.3.1 Operational

The build alternatives show minor changes (less than 1 percent) in regional pollutants, GHGs, and MSAT, and no local impacts are currently identified. As such, no mitigation is proposed for operational impacts.

3.3.3.2 Construction

Demolition and construction activities can result in short-term increases in fugitive dust and equipment-related particulate emissions in and around the project area. (Equipment-related particulate emissions can be minimized if the equipment is well maintained.) The potential air quality impacts would be short-term, occurring only while demolition and construction work is in progress and local conditions are appropriate.

The potential for fugitive dust emissions typically is associated with building demolition, ground clearing, site preparation, grading, stockpiling of materials, onsite movement of equipment, and transportation of materials. The potential is greatest during dry periods, periods of intense construction activity, and during high wind conditions.

IDOT's Standard Specifications for Road and Bridge Construction includes provisions on dust control. Under these provisions, dust and airborne dirt generated by construction activities will be controlled through dust control procedures or a specific dust control plan, when warranted. The contractor and IDOT will meet to review the nature and extent of dust-generating activities and will cooperatively develop specific types of control techniques appropriate to the specific situation. Techniques that may warrant consideration include measures such as minimizing track-out of soil onto nearby publicly traveled roads, reducing speed on unpaved roads, covering haul vehicles, and applying chemical dust suppressants or water to exposed surfaces, particularly those on which construction vehicles travel. With the application of appropriate measures to limit dust emissions during construction, the proposed project will not cause any significant, short-term PM air quality impacts. See also Section 3.14 for discussion of a communications plan to inform communities about construction activities and a project-specific dust control plan to reduce fugitive dust during construction.

Construction activity also may generate a temporary increase in MSAT emissions. Project-level assessments that render a decision to pursue construction emission mitigation will benefit from several technologies and operational practices that should help lower short-term MSAT. In addition, 23 USC 149, as amended by the Safe, Accountable, Flexible, Efficient Transportation Equity Act – A Legacy for Users (Public Law 109-59, August 10, 2005), places emphasis on a host of diesel retrofit technologies – technologies that are designed to lessen many MSAT.

Construction mitigation includes strategies that reduce engine activity or reduce emissions per unit of operating time (e.g., reducing the numbers of trips, extended idling). Operational agreements that reduce or redirect work or shift times to avoid community exposures can have positive benefits when sites are near populated areas. For example, agreements that stress work activity outside normal hours of an adjacent school campus would be operations-oriented mitigation. Verified emissions control technology retrofits or fleet modernization of engines for construction equipment could be appropriate mitigation strategies. Technology retrofits could include PM traps, oxidation catalysts, and other devices that provide an after-treatment of exhaust emissions. Implementing maintenance programs per manufacturers' specifications to ensure engines perform at USEPA certification levels, as applicable, and to ensure retrofit technologies perform at verified standards also could be deemed appropriate. The use of clean fuels (e.g., ultra-low sulfur diesel, biodiesel, natural gas) can be a very cost-beneficial strategy. Cleaner diesel fuel and idling restrictions are contained in Article 107.41 of the Standard Specifications for Road and Bridge Construction.

3.4 Traffic Noise

There have been no substantive changes to this section since publication of the DEIS.

Federal regulations for traffic noise assessment are in Title 23 CFR 772, *Procedures for Abatement of Highway Traffic Noise and Construction Noise*. IDOT developed traffic noise analysis procedures that are consistent with the federal regulations and are contained in its *Highway Traffic Noise Assessment Manual* (IDOT, 2011). These set forth procedures for traffic noise analyses, identification of noise impacts, and consideration of noise abatement where feasible and reasonable.

Noise is unwanted sound that can affect activities. Highway traffic noise is influenced by four main factors: traffic volumes, traffic speeds, truck volumes, and distance and topography between the highway and the location where the noise is heard. This section describes the noise environment along the Project Corridor, identifies traffic noise receptors, and predicts the existing, future No Build, and future build condition noise levels. An overview of noise abatement procedures is provided in this section. Noise abatement analysis is deferred to Section 5.0, Comparison of Alternatives (discussion provided in Section 3.4.3).

3.4.1 Affected Environment

The Noise Study Area is the traffic noise analysis area, and typically includes all areas within 500 feet of the edge of proposed improvements. This section describes FHWA and IDOT noise policies used to assess noise in the Noise Study Area, noise receptors identified for the Noise Study Area, procedures for the traffic noise impact analysis, traffic noise monitoring, and a description of the existing I-290 noise environment.

3.4.1.1 Traffic Noise Analysis Process

Federal policies for traffic noise assessment are in Title 23 CFR 772, *Procedures for Abatement of Highway Traffic Noise and Construction Noise*. IDOT traffic noise analysis procedures are listed in its *Highway Traffic Noise Assessment Manual* (IDOT, 2011).

The highway traffic noise analysis process consists of the steps listed below.

1. *Identify Places with Similar Noise Characteristics.* Common Noise Environments (CNEs) are areas with similar land use (by Activity Category, as listed in Table 3-32), noise exposure, topography, and traffic characteristics.
    a. Activity Categories B and C include land uses such as residences, schools, parks, and places of worship, and are the most noise-sensitive land uses[39] in the Project Corridor.
    b. Activity Category E includes land uses such as offices, hotels, and restaurants that also are studied for noise impacts.

[39] There are no land uses in the Project Corridor that qualify as Activity Category A or D uses.

Table 3-32. Noise Abatement Criteria

Activity Category[40]	$L_{eq}(h)$	Evaluation Location	Activity Description
A	57	Exterior	Lands on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose.
B	67	Exterior	Residential.
C	67	Exterior	Active sport areas, amphitheaters, auditoriums, campgrounds, cemeteries, day care centers, hospitals, libraries, medical facilities, parks, picnic areas, places of worship, playgrounds, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, recreation areas, Section 4(f) sites, schools, television studios, trails, and trail crossings.
D	52	Interior	Auditoriums, day care centers, hospitals, libraries, medical facilities, places of worship, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, schools, and television studios.
E	72	Exterior	Hotels, motels, offices, restaurants/bars, and other developed lands, properties or activities not included in A-D or F.
F	---	---	Agriculture, airports, bus yards, emergency services, industrial, logging, maintenance facilities, manufacturing, mining, rail yards, retail facilities, shipyards, utilities (water resources, water treatment, electrical), and warehousing.
G	---	---	Undeveloped lands that are not permitted.

2. *Select Noise Receptors*. Noise receptors are outdoor activity areas of frequent human use at noise-sensitive land uses (Activity Categories A–C, and E).[41] Only receptors that are typically located within 500 feet of the edge of the proposed roadway improvements are considered, as this is where noise impacts typically occur. There is one representative (worst-case) receptor per CNE.
3. *Monitor Existing Noise Levels at Selected Noise Receptors*. Existing noise levels are measured at selected locations. Noise monitoring is used to ensure the noise model is accurate and to collect ambient noise levels in locations where roadway noise is currently not the major noise source. Noise monitoring does not define impacts.

[40] Based on 23 CFR Part 772, *Procedures for Abatement of Highway Traffic Noise and Construction Noise* (adopted 2010).

[41] Activity Category D is the only category for which interior noise is studied, and only if no exterior areas of frequent human use exist. As shown in Table 3-32, Activity Category D includes uses such as recording studios and does not include residences.

4. *Model Noise Conditions*: Existing, future No Build, and future build conditions for the roadway, receptors, and topography are modeled using the FHWA Traffic Noise Model 2.5 (TNM).

    a. For the I-290 traffic noise analysis, the four build alternatives were separately modeled for build conditions.

    b. For all models, expressway traffic was modeled at posted speeds of 55 mph for free-flow conditions (regardless of any capacity constraints that could slow traffic). This method represents worst-case traffic noise conditions.

5. *Determination of Noise Impacts*: The predicted build condition noise levels are compared to the existing noise levels and to the FHWA Noise Abatement Criteria (NAC) to determine noise impacts. Table 3-32 summarizes the NAC noise levels for each type of land use in the Noise Study Area.

    c. Noise impacts are identified where future build noise levels approach, meet, or exceed the noise levels (by Activity Category) as identified in Table 3-32. The IDOT noise policy defines "approach" to be noise levels within 1 decibel [dB(A)] of the NAC (a noise level approaching the NAC of 67 dB(A) would be 66 dB(A)).

    d. In addition to using the NAC, noise impacts are identified for receptors where the future build condition noise is greater than 14 dB(A) compared to existing conditions.

6. *Noise Abatement Analysis for Impacted Receptors*. Noise abatement is assessed where noise impacts are predicted. The noise abatement analysis identifies abatement measures that are considered feasible to construct and reasonable with respect to cost and noise-reduction effectiveness. Viewpoints solicited from receptors that would be benefitted by the barrier occur when barriers are considered feasible, cost effective, and effective at reducing noise. Receptors that would be benefitted by the barrier are asked to vote if they support the barrier's construction. If more than 50 percent of received votes are in support of the barrier, the barrier will be recommended for construction.

3.4.1.2 Noise Receptor Identification

Receptor locations are selected at appropriate locations to evaluate changes in traffic noise levels as a result of changes in traffic volumes, speed, composition (trucks and cars), roadway alignment (horizontal and vertical), number of lanes, shielding, and ground cover. Distance to I-290 from the receptor was the primary factor used to select receptors for this analysis and was limited to receptors within 500 feet of the proposed improvements (Noise Study Area) in accordance with the IDOT traffic noise policy.

Noise receptors were located using aerial photography and field investigations to determine exterior areas of frequent human use, such as balconies, benches, or other gathering places, in accordance with the IDOT traffic noise policy. Receptors were studied on each floor of multistory buildings where outdoor areas of frequent human use existed (e.g., balconies on every story of a multistory apartment building) to determine which floor of the building constituted the worst-case noise level for the

building. Noise level results, shown in Table 3-33 in Section 3.4.2, identify the worst-case results for the representative noise receptor.

The traffic noise analysis evaluates the Noise Study Area using CNEs. Within each of the CNEs, the receptor with the worst-case traffic noise condition (typically the closest receptor to I-290) was selected to represent the CNE. The represented receptors within the CNEs would have similar traffic noise levels as the selected receptor.

Two hundred and eighty-eight (288) representative receptors and CNEs were identified in the Noise Study Area. These receptors are shown in the Section 3.0 Map Set.

3.4.1.3 Traffic Noise Monitoring

Field measurements and other data collected during noise monitoring are used to validate the traffic noise models used for analysis of the build alternatives, ensuring the models can accurately predict each area's noise environment. Noise monitoring for I-290 was conducted at 49 receptor locations representing the variety of land uses and noise environments present in the Project Corridor. These 49 locations were reviewed and approved by IDOT and FHWA.

Noise monitoring is typically conducted during the period representing the worst hourly noise level. This may or may not be during the peak-hour traffic volumes, as traffic may be stop-and-go or at a reduced travel speed during the peak hour. Monitoring for I-290 typically occurred during the midday off-peak travel period, when free-flow conditions were present on I-290 (generally 10:00 a.m. to 2:00 p.m.). Noise monitoring was conducted on April 9, 22, and 30; May 7, 14, 21, and 22; and October 30, 2014.

To validate the noise model, the noise monitoring results were compared to existing conditions noise modeling results using observed traffic volumes and conditions. The difference between modeled and monitored noise levels provides an indication of noise model representativeness. Monitored noise levels for the 49 monitored receptors ranged from 63 to 78 dB(A).[42] For this analysis, all monitored noise levels are within 3 dB(A) of the modeled noise levels, which validates the noise model per the IDOT traffic noise policy.

3.4.1.4 Existing I-290 Noise Environment

The Project Corridor is a high-volume urban expressway, with rail transit service (CTA Blue Line) included in the highway corridor from beyond the east project terminus to DesPlaines Avenue. The predominant sources of existing noise are the expressway and CTA transit service.

The western end of the Project Corridor contains several existing traffic noise barriers that were constructed during reconstruction of the I-290/I-88/I-294 interchange. Physical characteristics of the noise barriers were inventoried via aerial photography (location of

[42] The Traffic Noise Analysis Report, Volume 1 (Appendix F), provides a full listing of monitoring results compared to modeled results for the 49 monitored receptors.

the barrier) and field review (height of the barrier). Six noise barriers (11 to 13 feet tall) exist in the Hillside portion of the Project Corridor (Butterfield Road to Mannheim Road). Two noise barriers (12 to 16 feet tall) exist in the Westchester portion of the Project Corridor (between Mannheim Road and Bristol Avenue). Finally, two existing noise barriers (16 to 18 feet tall) exist in the Bellwood portion of the Project Corridor, from Bellwood Avenue to 30th Avenue.

Additionally, one traffic noise barrier is planned to be constructed within the Project Corridor as part of the Jane Byrne Interchange (formerly the Circle Interchange) project. The traffic noise analysis for the Jane Byrne Interchange found that a 23-foot-tall noise barrier between Throop Street and Racine Avenue was reasonable, feasible, and supported by those who would benefit from the barrier. Reconstruction of the Jane Byrne interchange is currently in progress, and the planned noise barrier was included in the I-290 traffic noise models for the 2040 No Build and 2040 Build conditions, but it was not included in existing conditions.

Existing modeled noise levels range from 57 dB(A) at R256 to 78 dB(A) at R100, R119, R172, R198, and R206. The projected No Build 2040 traffic noise levels range from 57 dB(A) at R256 to 79 dB(A) at R119 and R172. Receptor noise levels either remain the same or increase up to 3 dB(A) from the existing condition to the 2040 No Build condition; most of the receptors have no change or a 1 dB(A) increase in noise from existing to 2040 No Build.

Existing and 2040 No Build noise levels were compared to the NAC for reference purposes.[43] Noise levels approached, met, or exceeded the NAC at 220 representative receptors for the existing condition and at 227 representative receptors for the 2040 No Build condition. Existing and 2040 No Build noise levels are highest where receptors are closest to I-290 and have an unimpeded line of sight from the receptor to the roadway; these receptors are located throughout the Project Corridor. For a full listing of existing and 2040 No Build noise levels, refer to Table 3-33.

[43] Per IDOT policy, traffic noise impacts are identified only for the future build condition, not for the existing or future No Build condition. Comparisons of the existing and future No Build noise levels to the NAC are for comparison purposes only.

Note: Noise impacts identified in **BOLD** text. The IDOT noise policy defines approach to be noise levels within 1 dB(A) of the NAC.

[1] Refer to Section 3.0 Map Set for receptor locations.

3.4.2 Environmental Consequences

This section describes traffic noise impacts that would be associated with the four build alternatives.

The I-290 mainline geometry and traffic volumes are the primary traffic noise influences in the Project Corridor. The build alternatives' average 2040 projected corridor traffic volumes (all vehicles) include, from smallest to largest:

- HOT 3+ and TOLL Alternative [2040 corridor average annual average daily traffic (AADT) of 187,853 vehicles per day (vpd)];
- Existing Condition (corridor average AADT of 191,020 vpd);
- No Build Alternative (2040 corridor average AADT of 204,227 vpd);
- HOV 2+ Alternative (2040 corridor average AADT of 211,247 vpd);
- HOT 3+ Alternative (2040 corridor average AADT of 214,760 vpd); and
- GP Lane Alternative (2040 corridor average AADT of 222,507 vpd).

Traffic noise was assessed at the 288 representative noise receptors identified in the Project Corridor. The four build alternatives share the same design, but they have different traffic volumes due to the effects of the different managed lanes and tolling scenarios. The differences in traffic volumes influenced the slight differences in sound levels among the build alternatives. The collective Build 2040 traffic noise levels range from 57 dB(A) at R256 to 79 dB(A) at R44, R100, R101, and R119. Typically, the four build alternatives carried forward have similar noise levels to the 2040 No Build condition, with several receptors experiencing noise increases as much as 2 dB(A) from the 2040 No Build condition.

Table 3-34 summarizes the number of representative receptors for each build alternative that approach, meet, or exceed the NAC. Of the four build alternatives, the HOT 3+&TOLL Alternative has the fewest receptors that approach, meet, or exceed the NAC (220 receptors, or 76 percent of all studied receptors), while the GP Lane Alternative has the greatest number (230 receptors, or 80 percent of all studied receptors are impacted). The existing condition also would have 220 receptors that would exceed the NAC.[44] The findings for the No Build Alternative and the four build alternatives are similar, ranging from 220 representative receptors exceeding the NAC (HOT 3+&TOLL Alternative) to 230 receptors (GP Lane Alternative).

[44] Per IDOT policy, traffic noise impacts are identified only for the future build condition, not for the existing or future No Build condition. Comparisons of the existing and future No Build noise levels to the NAC are for comparison purposes only.

Table 3-34. Traffic Noise Impacts Summary by Build Alternative

	GP Lane (2040) Alternative	HOV 2+ (2040) Alternative	HOT 3+ (2040) Alternative	HOT 3+ TOLL (2040) Alternative
Receptors with Traffic Noise Impacts	230	228	229	220

The GP Lane Alternative had the greatest amount of traffic noise impacts among the four build alternatives, followed by the HOT 3+ Alternative and the HOV 2+ Alternative. The slight difference in traffic noise impacts among the build alternatives correlates to their traffic volume differences.

- The HOT 3+ &TOLL Alternative was found to have the least amount of traffic noise impacts among the build alternatives, and this alternative also has the lowest projected traffic volumes of the four build alternatives.
- Conversely, the GP Lane Alternative was found to have the highest amount of traffic noise impacts, and this alternative also has the highest projected traffic volumes of the four build alternatives.

However, the mainline volume differences do not account for all of the variation among the noise level findings. Although the existing condition has slightly higher traffic volumes than the 2040 HOT 3+ &TOLL Alternative, the existing condition model results are the same or lower than the HOT 3+ &TOLL Alternative. This is due to the influence of arterial street traffic volume growth that is assumed to occur in the future year.

Individual findings that do not directly correlate to the above-noted I-290 mainline traffic volume trends or changes in arterial street volumes include:

- At R34, the proposed interchange geometry change at 25th Avenue (from a partial cloverleaf interchange to an SPUI) is reflected in the noise results. In the existing and 2040 No Build conditions, Harrison Street west of 25th Avenue (north of I-290) carries local traffic and traffic for the 25th Avenue interchange westbound on-ramp. In the build condition, the westbound on-ramp traffic is rerouted from Harrison Street to the new SPUI interchange ramp. As a result, there is less traffic on the frontage road resulting in 2040 Build traffic noise levels that are as much as 8 decibels lower than that of the 2040 No Build (R34). R35, R32, and R33 also are influenced by the proposed 25th Avenue interchange design.
- At R76 and R76A (representative receptors in the northwest quadrant of the IL 43/ Harlem Avenue interchange), the existing and 2040 No Build traffic noise levels would be the same or greater than those of the 2040 build alternatives. The 2040 build noise levels decrease due to the addition of vertical retaining walls needed to support the proposed Harlem Avenue interchange ramps. These walls reduce the noise level of the mainline noise (the greatest noise source) that reaches the representative receptors.

- Due to the proposed lower I-290 mainline elevation through Oak Park in combination with the proposed Harlem Avenue and Austin Boulevard interchange designs, additional shielding would be provided to receptors along the north side of I-290 through Oak Park, such as R79 (Wenonah Tot Lot, Oak Park, north side of I-290).

None of the Noise Study Area receptors are considered impacted due to a substantial increase (greater than 14 dB(A) increase) in traffic noise levels. For the four build alternatives, most of the Project Corridor representative receptor locations approach or exceed the FHWA NAC; therefore, they warrant a noise abatement analysis.

3.4.3 Mitigation

Due to the similarity of the noise impacts among the alternatives and the density of the receptors in the Project Corridor, each of the four build alternatives would study the same locations for noise barrier analysis. These locations are shown as "noise barrier study areas" in the Section 3.0 Map Set. Barriers were studied throughout the Project Corridor. All areas with existing noise barriers (Hillside, Bellwood, Westchester, and Chicago) were found to have noise impacts, and the existing noise barriers were assessed for potential height increases or length extensions associated with the alternative identified as the Preferred Alternative. Based on the noise impact findings for the four build alternatives, most of the remaining corridor and nearly all areas with noise-sensitive uses (identified by CNEs; Section 3.0 Map Set) were studied for noise abatement. All residential areas directly adjacent to the corridor were found to have noise impacts with the Preferred Alternative and were studied for noise abatement.

A full noise abatement analysis was completed for the Preferred Alternative (Section 5.0, Comparison of Alternatives and Appendix F). However, the similarity of the four build alternatives, paired with the characteristics of the Project Corridor, support that the four build alternatives, regardless of the alternative selected as the Preferred Alternative, would have very similar feasible and reasonable barrier design characteristics, as a result of:

- The four build alternatives share the same roadway geometry.
- Traffic predictions vary for the four build alternatives, but at the peak-hour level of analysis, traffic varies slightly among the four alternatives, and typically not to a degree that causes wide differences in noise impacts. All traffic conditions studied (existing, future no build, and the four build alternatives) would result in traffic noise levels that approach, meet, or exceed the NAC. Noise levels varied by condition studied, but the variation was slight. Seventy-six (76) to 80 percent of receptors studied approached, met, or exceeded the NAC (hereafter described as "exceeded the NAC"), and as traffic volumes increased with the future conditions, the percentage of receptors exceeding the NAC increased only slightly.
- Generally, there is a high density of receptors in the areas where I-290 noise barriers were studied. For this project, if a receptor was impacted by one build alternative

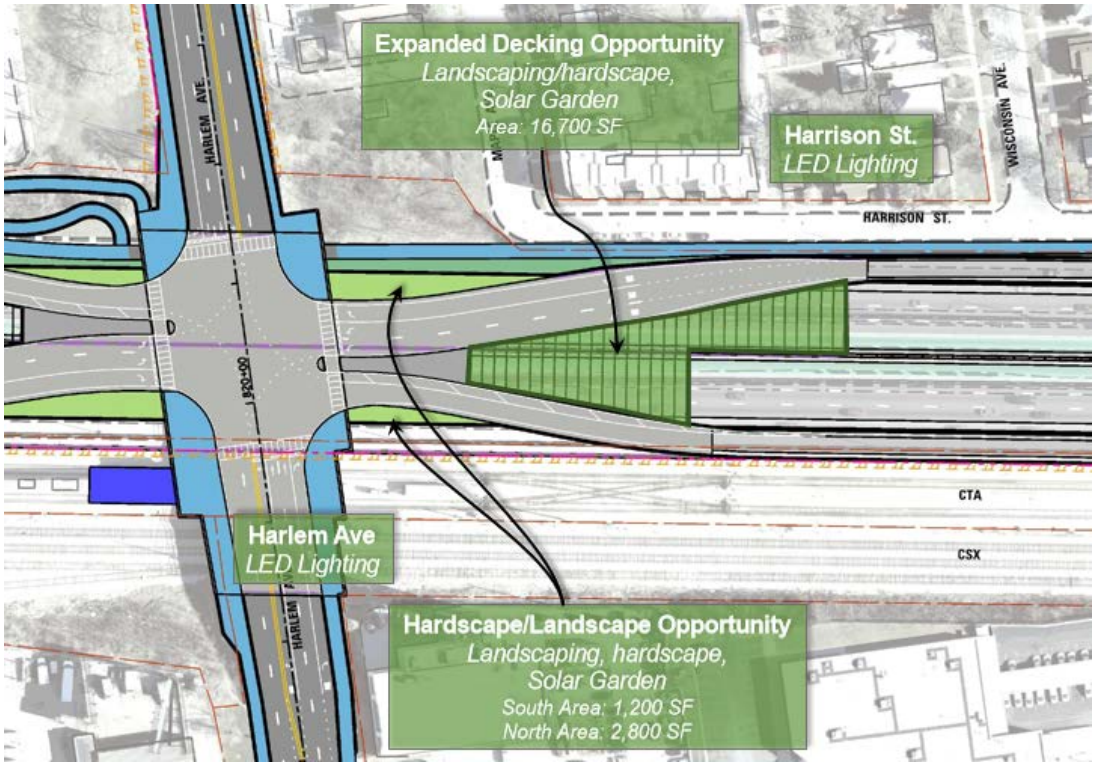
and not another, there was another impacted receptor in the same area behind the same studied barrier.

As part of the full noise abatement analysis completed for the Preferred Alternative, 92 wall locations were studied to mitigate the noise impacts, including the extension of three existing barriers and the potential height increase of 10 existing barriers. Of these 92 barrier locations, 63 were found to be reasonable and feasible. The 63 feasible and reasonable noise barriers were presented in November 2015 and August 2016 to the public to be voted on through the viewpoint solicitation process. Of the 63 feasible and reasonable noise barriers, the benefited receptors voted in favor of 46 noise barriers (refer to Section 3.0 Map Set). These 46 barriers would benefit 4,027 receptors.

3.5 Energy

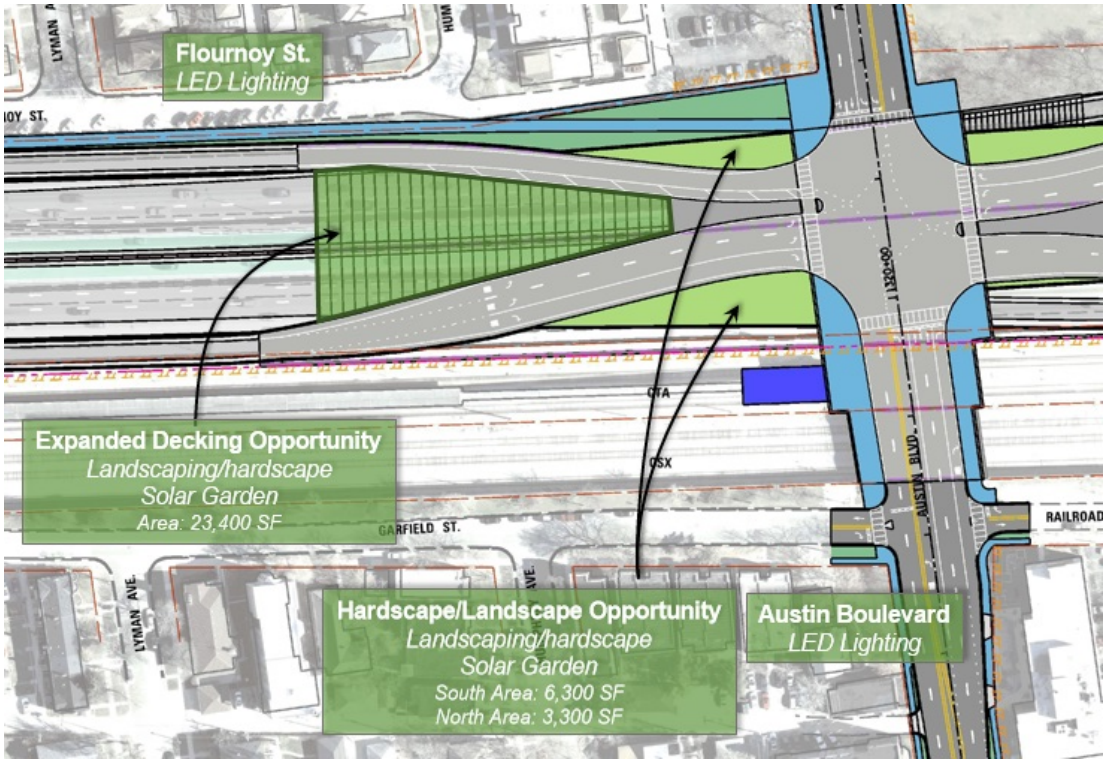
There have been no substantive changes to this section since publication of the DEIS.

Construction of the proposed I-290 Eisenhower Expressway improvement would require indirect consumption of energy for processing material, construction activities, and maintenance for the lane miles to be added within the project limits. Energy consumption by vehicles in the area may increase during construction due to possible traffic delays.



Construction of the proposed improvement would reduce traffic congestion and turning conflicts along the route and thereby reduce vehicular stopping and slowing conditions. Additional benefits would be realized from increased capacity and smoother riding surfaces. This would result in less direct and indirect vehicular operational energy consumption for the build alternatives than for the No Build Alternative. Thus, in the long-term, post-construction operational energy requirements should offset construction and maintenance energy requirements and result in a net savings in energy usage.

The proposed project includes provisions for improved bicycling and walking conditions, thereby encouraging travel by these nonmotorized and nonenergy-consuming modes of transportation.



The Village of Oak Park also is exploring the opportunity to install solar gardens in conjunction with the proposed project. The Village is considering applying solar panel technology to noise walls where proposed and/or where space may be available as part of the proposed project. Two such opportunity areas occur where expanded bridge decking is proposed over the expressway at Harlem Avenue and Austin Boulevard (Figure 3-54). IDOT would work with the Village to accommodate these features as these opportunities are further refined. Nonstandard features and/or incremental cost difference over standard features would require Village cost participation and maintenance responsibility.

Figure 3-54. Potential Solar Garden Areas – Village of Oak Park

Harlem Avenue

Austin Boulevard

Since publication of the DEIS, the following substantive change to this section has been made:

- Section 3.6.1.3 was updated to state that the rusty patched bumble bee is now endangered, and is no longer proposed as endangered.

The natural resources within the Project Corridor are limited in extent and quality, but they generally consist of common/adaptable species. This section addresses vegetation, wildlife, and threatened and endangered species.

3.6.1 Affected Environment

3.6.1.1 Vegetation and Cover Types

Table 3-35 summarizes the land cover within the Project Corridor based on information from the CMAP *2005 Land-use Inventory (Version 1.0)*.

Table 3-35. Land Cover within the Project Corridor

Cover Type	Acres	Percent of Total Land Cover within Project Corridor
Transportation	530	66
Residential	106	13
Industrial	81	10
Commercial	38	5
Open Space/Vacant/Under Construction	27	3
Institutional	19	2
Water	<1	<1
Total	**800**	**100**

Source: CMAP, 2005.
Note: Land use acreages are from CMAP and may vary from data provided by other sources found in other tables within this document. Numbers in table have been rounded. Percentages may not total 100.

The Project Corridor is approximately 800 acres (1.25 square miles) in size. Approximately 97 percent of the total cover is urban and built-up land. In high-density areas, nearly all of the land surface is covered with built structures, such as buildings, roads, parking lots, and driveways. The high percentage of impervious surface provides limited cover, foraging, and resting areas for wildlife. In areas of low/medium density, up to half of the land surface is covered with built structures. The remaining surface area is intermixed with urban landscaping, open space, or forested cover, which provide more area for foraging and cover habitat. Urban open space includes parks, golf courses, cemeteries, and other grass-covered surfaces within developed areas.

Of the land cover types listed in Table 3-35, the most important for wildlife are open space/vacant lands and surface water, which comprise less than 4 percent of the Project Corridor. Within the Project Corridor, there are no large contiguous wooded areas. Open space and surface waters provide important habitat for many species of plants and wildlife. Section 3.7, Water Resources and Aquatic Habitats, and Section 3.10, Wetlands, discuss the general distribution of aquatic/wetland habitats.

Field reconnaissance near the proposed transportation improvements found that most of the open space habitat consists of cemeteries located north and south of I-290 along the Des Plaines River. The Thomas Jefferson Woods and Miller Meadows Forest Preserves of Cook County are located outside the Project Corridor north and south of the cemeteries, respectively. The only other large open areas are located within the I-290/ US 45 interchange. The cemeteries consist of mowed turf and scattered trees. There are no high-quality natural areas located within the Project Corridor.

Trees

A survey to identify tree resources within impacted areas of the Project Corridor was conducted in November 2016 (Huff & Huff, Inc., 2016). The tree survey was completed according to IDOT Departmental Policies (D&E – 18) *Preservation and Replacement of Trees.* Trees with a diameter at breast height (dbh) of 6 inches or greater, as well as trees with a dbh less than 6 inches when such have been intentionally planted for landscaping, environmental mitigation, or habitat preservation/enhancement purposes, were identified within impacted areas of the Project Corridor. Overall tree health and structure were also assessed for identified trees. Trees were inventoried using the Direct Counting Method.

No forested areas greater than 20 acres are located within the Project Corridor. The majority of the Project Corridor contains scattered trees within the roadway rights-of-way, as well as landscaped trees within adjacent residential and commercial land. Limited tree resources are located within floodplains and riparian areas. A total of 3,660 trees are located within impacted areas of the Project Corridor (Huff & Huff, Inc., 2016). Sixty-nine (69) species of trees were identified in impacted areas of the Project Corridor. The most common species identified include honey locust *(Gleditsia triacanthos*, 12 percent) and green ash *(Fraxinus pennsylvanica*, eight percent). Approximately 60 percent are considered landscaped and 40 percent are considered volunteer (a plant that grows on its own). Table 3-36 summarizes the total number of landscaped and volunteer trees present within each municipality of impacted areas of the Project Corridor. It should be noted that many of the green ash trees within impacted areas of the Project Corridor appeared to be infected with the Emerald Ash borer. Regardless of the proposed project, many if not all of the ash trees would need to be removed in the future due to the Emerald Ash borer.

Table 3-36. Tree Data by Municipality

Municipality	Total Trees	Percent of Total*
Bellwood	444	5
Broadview	164	2
Chicago	4,094	50
Forest Park	636	8
Hillside	1,587	20
Maywood	689	9

Westchester	199	2
Total	**8,152**	**100**

Source: Huff & Huff, Inc., 2016.
*Total may not equal 100 percent due to rounding.

3.6.1.2 Wildlife

The Project Corridor contains limited areas of wildlife habitat. Roughly 97 percent of the Project Corridor is urban and built-up land (Table 3-35). Development in the Project Corridor has limited the distribution of sensitive wildlife species to protected lands, such as forest preserves. There are no forest preserves within the Project Corridor; however, there are forest preserves north and south of the Project Corridor along the Des Plaines River. Overall, urban development and habitat fragmentation limits wildlife movement throughout much of the Project Corridor.

The developed parts of the Project Corridor provide minimal wildlife habitat. Wildlife species in urban/suburban areas tend to be tolerant of disturbance and human activities. Some would use urban and suburban habitats, but species diversity generally is lower than in forest preserves and rural habitats. Urban-tolerant wildlife species are generally common, adaptable species and include limited numbers of mammals, birds, reptiles, and amphibians. Aquatic species, such as fish, mussels, and crustaceans, are discussed in Section 3.7, Water Resources and Aquatic Habitats. A wildlife survey was not conducted as part of the study; instead, national and state databases were searched for wildlife information.

Invasive Species

Invasive species are those not native to a particular ecosystem, whose introduction does or is likely to cause harm to the associated habitat, environment, economy, or human health. Under EO 13112 *(Invasive Species),* federal agencies are required to identify, control, and minimize/prevent actions that may cause or promote the introduction or spread of invasive species. Invasive species should be considered during all phases of the environmental process to meet NEPA requirements.

Based on available data, the US Department of Agriculture (USDA)-Natural Resources Conservation Service (NRCS) *Noxious Weeds List for Illinois* includes invasive plant species that have been recorded within Cook County, such as Canada thistle *(Cirsium arvense),* common ragweed *(Ambrosia artemisiifolia),* and giant ragweed *(Ambrosia trifida).*

Additional invasive plant species dominate many of the upland habitats in the Project Corridor, such as common buckthorn *(Rhamnus cathartica),* garlic mustard *(Alliaria petiolata),* Tartarian honeysuckle *(Lonicera tatarica),* and teasel *(Dipsacus* sp.).

Invasive species also include aquatic nuisance species and injurious wildlife species that can potentially harm an ecosystem. Examples of aquatic nuisance species and injurious wildlife that have been recorded from the Project Corridor include the common carp (*Cyprinus carpio*).

3.6.1.3 Threatened and Endangered Species

Threatened and endangered species assessments were conducted using published databases and field review of available habitat. Threatened and endangered species clearances were provided for the project on April 10 and December 13, 2014 (Appendix G-1).

Federal-Listed Species

A review of the US Fish and Wildlife Service (USFWS) list for threatened and endangered species was conducted in November 2016. The list is made accessible and provided by USFWS as part of the initial Section 7 Consultation process. Table 3-37 summarizes the USFWS list for threatened and endangered species known to occur within Cook County, Illinois.

On January 14, 2016, USFWS issued the Endangered and Threatened Wildlife and Plants; 4(d) Rule for the Northern Long-Eared Bat (50 CFR Part 17, 2016; Appendix G-2). There are no known hibernacula within the Project Corridor. No buildings would be removed as part of this project. Although existing bridges would be demolished and replaced, the lack of habitat and connectivity to habitat to these bridges limits the use of these structures by bats. In addition, there are no known maternity roost trees within the Project Corridor or within 150 feet of the Project Corridor (Appendix G-2). The absence of the northern long-eared bat was determined during the Section 7 consultation conducted by FHWA on December 13, 2013, given the urban environment, proximity to downtown Chicago, and lack of trees adjacent to an existing multi-lane expressway. Therefore, the proposed project would *not affect* the northern long-eared bat and potential suitable roosting habitat was not assessed. The proposed project would meet the Final 4(d) Rule (50 CFR Part 17, 2016).

The project is not within a "high potential zone" for the endangered rusty patched bumble bee, as established by USFWS historical records of observation for the species. Per USFWS guidance, since the project is not within a "high potential zone" for the rusty patched bumble bee, the species is not likely to be encountered within the I-290 project corridor. The rusty patched bumble bee will not be affected by the proposed I-290 action.

Table 3-37. Federally Listed Threatened and Endangered Species within Cook County

Species	Status	Habitat	Habitat Present in Project Corridor?
Piping Plover *(Charadius melodus)*	Endangered	Lakeshore beaches.	No
Hine's emerald dragonfly *(Somatochlora hineana)*	Endangered	Spring-fed wetlands, wet meadows and marshes.	No
Leafy prairie clover *(Dalea foliosa)*	Endangered	Prairie remnants on thin soil over limestone.	No
Rusty patched bumble bee	Endangered	Grasslands with flowering plants from April through October, underground and abandoned rodent cavities or clumps of grasses above ground as nesting sites, and undisturbed soil for hibernating queens to overwinter.	No
Northern long-eared bat *(Myotis septentrionalis)*	Threatened	Hibernates in caves and mines, swarming in surrounding wooded areas in autumn. Roosts and forages in upland forests and woods and human structures such as buildings and bridges.	No
Eastern prairie fringed orchid *(Platanthera leucophaea)*	Threatened	Moderate to high-quality wetlands, sedge meadow, marsh, and mesic to wet prairie.	No
Mead's milkweed *(Asclepias meadii)*	Threatened	Late successional tallgrass prairie, tallgrass prairie converted to hay meadow, and glades or barrens with thin soil.	No
Prairie bush clover *(Lespedeza leptostachya)*	Threatened	Dry to mesic prairies with gravelly soil.	No
Eastern massasauga rattlesnake *(Sistrurus catenatus)*	Threatened	Graminoid-dominated plant communities (fens, sedge meadows, peatlands, wet prairies, open woodlands, and shrublands).	No
Rattlesnake master borer moth *(Papaipema eryngii)*	Candidate	Undisturbed prairie and woodland openings that contain their only food plant, rattlesnake-master *(Eryngium yuccifolium).*	No
Rufa red knot *(Calidris canutus rufa)*	Threatened	Along coastal areas or large wetland complexes during migratory window of May 1 through September 30.	No

Source: USFWS, 2016.

In summary, the proposed project would not affect the species listed in Table 3-37.

State-Listed Species

Based on information provided by the Illinois Department of Natural Resources (IDNR) and Illinois Natural Heritage Database, 117 species are state-listed threatened or endangered species within Cook County (Table 3-38).

Table 3-38. State Listed Threatened and Endangered Species within Cook County

Type of Species	Number of Species Listed
Plant	91
Bird	13
Fish	4
Insect	3
Reptile	3
Amphibian	1
Small Mammal	1
Mussel	1

Source: Illinois Endangered Species Protection Board, 2014.

The Ecological Compliance Assessment Tool (EcoCAT) reviewed on November 4, 2014, indicated the banded killifish *(Fundulus diaphanus)* as potentially within the Project Corridor. A review of the Natural Heritage Database (2016) found no record of the banded killifish in the Project Corridor.

3.6.2 Environmental Consequences

3.6.2.1 Habitat Loss and Fragmentation

The build alternatives are located predominantly in developed areas associated with existing roadways. All four build alternatives would result in the same impacts to habitat. A total of 10 acres of existing nonpaved surface area would be converted to paved roadway surface.

The build alternatives would not fragment any contiguous forested parcels or wooded riparian corridors larger than 20 acres. The density of trees within impacted areas of the Project Corridor is highly varied, with the highest density of trees located within right-of-way areas that are not actively mowed. The build alternatives may potentially impact 3,884 trees. Fifty-seven (57) species of trees were identified within the potentially impacted areas. The most common species identified that are potentially impacted include honey locust (12 percent) and Siberian elm *(Ulmus pumila*, nine percent). Table 3-39 summarizes the total number of potentially impacted landscaped and volunteer trees present within each municipality.

Table 3-39. Potentially Impacted Trees by Origin and Municipality

Municipality	Landscaped Trees	Volunteer Trees	Total	Percent of Total*
Bellwood	305	139	444	11
Broadview	27	137	164	4
Chicago	706	224	930	24
Forest Park	122	514	636	16
Hillside	534	49	583	15
Maywood	112	567	679	17
Oak Park	229	78	307	8
Westchester	87	54	141	4
Total	2,122	1,762	3,884	99

Source: Huff & Huff, Inc., 2016.
*Total may not equal 100 percent due to rounding.

3.6.2.2 Wildlife

Developed areas associated with existing roadways provide poor wildlife habitat. Wildlife that use the available habitat tend to be tolerant of disturbance and human activities. Urban-tolerant wildlife species are generally common adaptable species and include limited numbers of birds, mammals, reptiles, and amphibians.

Habitat for the peregrine falcon *(Falco peregrinus),* since delisted as a state threatened species and now protected by the Migratory Bird Treaty Act, is present within the Project Corridor. No peregrine falcons or avian nests were identified within the Project Corridor during the tree survey (Huff & Huff, Inc., 2016); however, known peregrine falcon occurrences and occurrence buffer areas were determined to be located a sufficient distance away from the Project Corridor to not be impacted by the proposed project (Appendix G-1).

Overall, project-related impacts to wildlife associated with the build alternatives would be minimal. Construction (e.g., grading and equipment operation) could also result in wildlife impacts, as can traffic and construction noise. Many mobile wildlife species would avoid harm due to construction operations, but some mortality is expected, especially to small mammals, amphibians, and reptiles that might be present in construction areas.

Direct conversion of approximately 10 acres from nonpaved cover to paved areas would result in the loss of wildlife habitat for breeding, foraging, and resting. Impacts to wildlife could involve limited population reductions of species or displacement associated with the habitat within the construction limits of the proposed project. The Project Corridor contains limited areas of wildlife habitat, and it is expected that the overall effect on wildlife using those areas would be minimal**.** Of the land cover types listed in Table 3-35, the most important type in the Project Corridor for wildlife is open space and surface waters. A small amount of urbanized open space would be converted

to paved areas per CMAP's *2005 Land-use Inventory (Version 1.0)*. Aerial photography indicates additional open space (pervious surfaces) located within land defined by CMAP as transportation use (typically roadway rights-of-way). The majority of the 10 acres that would be converted from nonpaved cover to paved areas would occur within the existing transportation right-of-way between Mannheim Road and Harlem Avenue. Limited wildlife habitat present within this area is degraded due to the adjacent expressway, rail transit, and freight rail, as well as surrounding residential land, existing access restriction fence and noise walls, and a limited riparian corridor associated with Addison Creek.

No impacts to forest preserves or state-designated lands are proposed. Because the proposed project consists primarily of improvements to existing roads and land already dedicated to transportation infrastructure close to developed land, impacts to wildlife habitat are minimal.

Habitat fragmentation divides larger continuous habitat into smaller habitat patches, reducing habitat function and value. The build alternatives would result in very little fragmentation because the area is within existing transportation corridors. Edge habitat is the boundary between habitat types and is often associated with urbanized areas. Some species identified near the Project Corridor, such as the American robin *(Turdus migratorius),* prefer edge habitat. Most land impacted by the build alternatives are urbanized and include edge habitat. Minimal disruption of the habitat edge is anticipated from the build alternatives because most improvements are within existing rights-of-way.

3.6.2.3 Barriers to Wildlife Movement

Development of the build alternatives considered avoidance, minimization, and mitigation of natural resource impacts. The build alternatives primarily include improvements to existing roadways or addition of a new travel lane. These roadways are already barriers to wildlife movement. Existing roadside barriers, such as fences and jersey walls, are expected to remain in place or be replaced if impacted; fences and jersey walls may restrict wildlife from entering roadways. They can also trap wildlife on the roadway, allowing no means of escape. Short barrier walls that would be implemented as necessary near creek crossings typically restrict the movement of small animals (including reptiles, amphibians, and smaller mammals) from entering the roadway corridor. The walls, however, would not limit the movement of larger mammals to prevent them from being trapped within the roadway.

3.6.2.4 Operational Mortality

Operational mortality would most likely result from vehicle/wildlife collisions along the proposed facility. The Project Corridor is located in an urban setting, and the land use tends to limit the extent and frequency of wildlife use compared to rural areas and large protected open space. The majority of potential vehicle/wildlife collisions would be with common animal species near existing greenways crossed by the build alternatives [e.g., Addison Creek (Figure 3-55), Des Plaines River (Figure 3-56)]. It is expected that minimal to no species loss would occur from either the No Build Alternative or build alternatives, given the heavily urbanized area.

Figure 3-55. Addison Creek, north of I-290

Figure 3-56. Des Plaines River, north of I-290

Source: Field Photo (Huff & Huff), 2014.

3.6.3 Measures to Minimize Harm and Mitigation

Avoidance and minimization of impacts to natural resources (including upland plant communities and wildlife resources) was an important component in the development and evaluation of the build alternatives.

3.6.3.1 Upland Plant Communities

The build alternatives have been designed to utilize existing roadways and rights-of-way to the extent practicable, which would minimize disturbances to undeveloped open space and commercially developed areas. No roadway alignments go through large tracts of undisturbed open space or wooded land, and disturbances would be limited primarily to edge impacts associated with widening and improving existing roadways and rights-of-way.

In the future design phase and during construction, IDOT will investigate and implement measures to minimize impacts to tree resources.

These measures include:

- Implementation of proper soil erosion and sediment control measures to minimize sediment deposition and indirect adverse impacts in wooded wetland and riparian zones; and
- Construction fencing and exclusion zones to reduce compaction of roots and soil.

Adverse impacts to trees will be reduced and minimized by implementing a tree protection and preservation plan that may include guidance regarding root pruning in critical root zones close to site grading, tree trunk and/or dripline protection measures, and establishment of exclusion zones to protect wooded land outside the proposed construction limits.

Mitigation of tree resources will comply with guidelines established by IDOT for tree replacement. Tree and vegetation replacement will be guided by IDOT's *Preservation and Replacement of Trees* (IDOT, 2002) policy and Chapter 59 ("Landscape Design") of the *BDE Manual* (IDOT, 2014).

Guidelines for replacement of trees and vegetation include the following:

- Replace impacted woodland areas, including woody riparian corridors, and trees that provide screening with tree plantings intended to provide comparable functional values within the right-of-way, to the extent practicable. When this cannot be achieved, plantings outside the right-of-way will be considered;
- Plant replacement trees in suitable locations as close as practical to the removal site;
- Plant no ash trees of any variety within the Project Corridor to help control spread of the emerald ash borer;
- Restore disturbed areas with vegetation as appropriate, with emphasis on native species;

- Encourage contractors to use locally produced (within 200 miles) materials; and
- Plant vegetation that has low maintenance requirements.

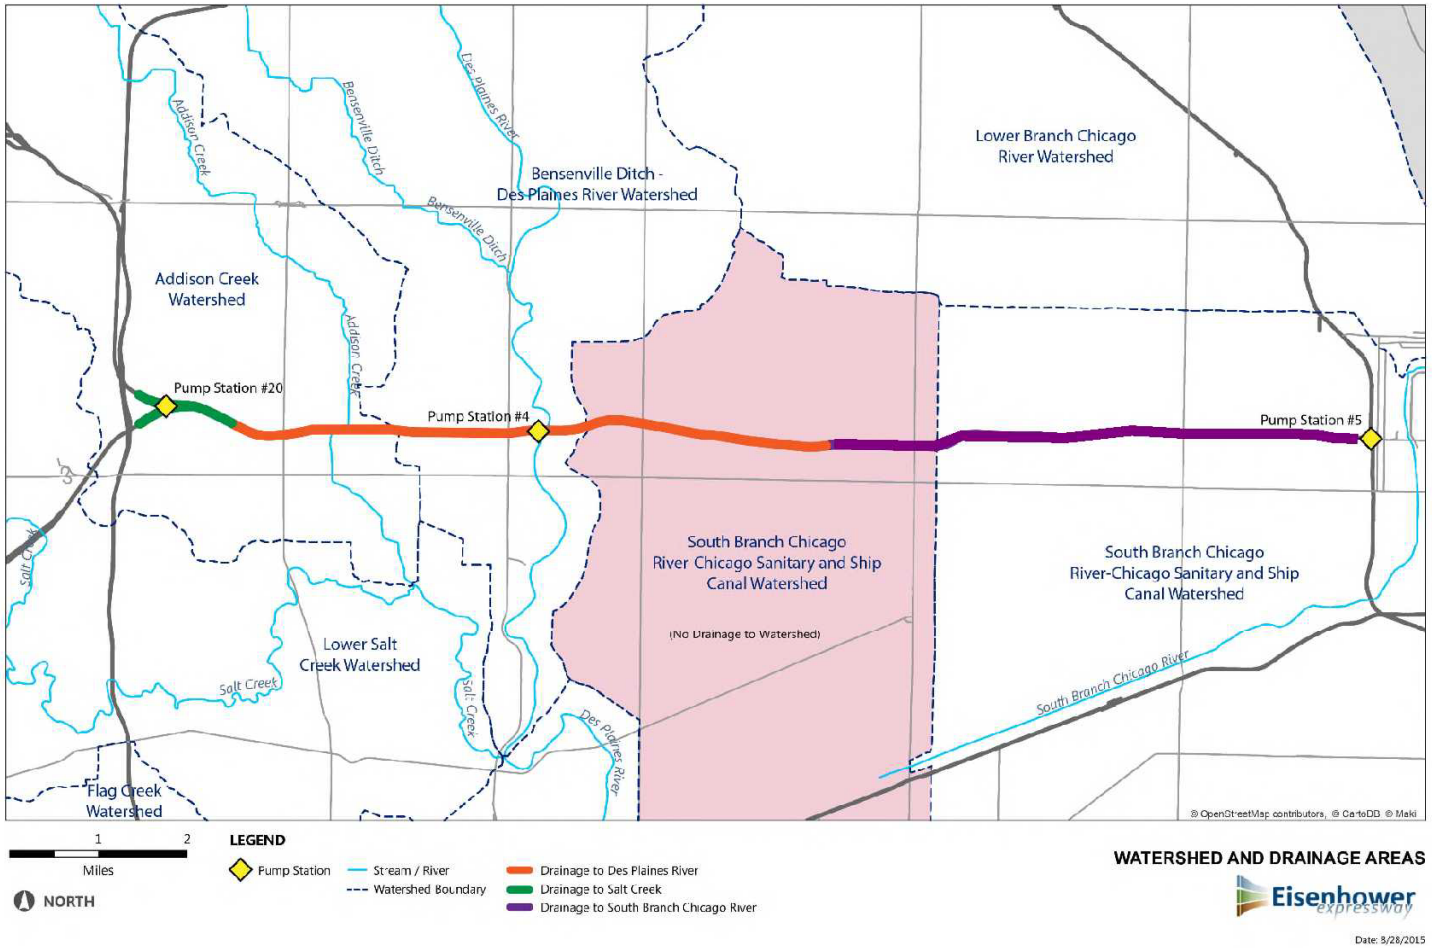
Disturbance of streamside/riparian vegetation will be kept to a minimum. Areas that are disturbed will be stabilized in accordance with National Pollutant Discharge Elimination System (NPDES) and Clean Water Act (CWA) Section 404 permit requirements. Erosion controls, stormwater quality/quantity best management practices (BMPs) (e.g., compensatory floodplain storage, bioswales), trees, shrubs, and other appropriate vegetation will be installed near streams to mitigate for riparian impacts.

A landscaping plan will be developed during the design phase that will identify areas where trees, shrubs, and grasses will be planted on highway side slopes, on back slopes, and in the median, except where clear vision needs to be maintained at highway entrances and exits, intersections, and median openings. Landscape trees and shrubs will be planted along post-construction parkways adjacent to existing commercial and residential developments to replace aesthetic woodland functions and values, as necessary.

3.7 Water Resources and Aquatic Habitats

Since publication of the DEIS, the following substantive change to this section has been made:

- Updated Section 3.7.1.4 with water quality standards to conform with current standards;
- Identification of a proposed underground storage vault at Kostner Avenue to provide additional capacity to supplement the existing trunk sewer; and
- Identification of a proposed new outlet to the Des Plaines River to separate ComEd stormwater runoff from Pump Station 4.



This section describes the physical, biological, and chemical characteristics of surface waters in the Project Corridor, including their associated aquatic habitats. An evaluation of these characteristics can provide an indication of water quality and a baseline from which potential water quality impacts can be assessed. Wetland resources are discussed in Section 3.10.

This section also discusses impacts to surface water resources that would be associated with the construction, operation, and maintenance of the alternatives, including the pollutants that could be deposited into receiving waters, potential impacts to water quality, and direct impacts through construction and the placement of fill material. Pollutants, such as sediments, solids, heavy metals (e.g., lead, zinc, and copper), oil and grease, deicing chemicals, and fertilizers/nutrients, may be released into the environment during construction or may accumulate on roadway surfaces and adjoining rights-of-way as a result of motor vehicle operations and maintenance. These pollutants were evaluated for potential impacts upon water quality. Measures to minimize and mitigate these impacts are also described.

3.7.1 Affected Environment

The Project Corridor is within the Des Plaines River drainage basin, Hydrologic Unit Code (HUC) 07120004, and the Chicago River drainage basin, HUC 07120003, as catalogued by the US Geological Survey (USGS). The Des Plaines River and the Chicago River drainage basins have been divided into several sub-watersheds near the Project Corridor, including Salt Creek, Addison Creek, Upper Des Plaines River, Lower Des Plaines River (main stem), and South Branch of the Chicago River (Figure 3-57). The Project Corridor crosses Addison Creek and the Des Plaines River main stem. All stormwater collected within the Project Corridor is currently directed into a storm sewer system. In the western section of the project, Wolf Road to I-294, the storm sewer system drains to Pump Station 20 and ultimately discharges to Salt Creek. Stormwater runoff from Wolf Road to Central Avenue drains to Pump Station 4 and discharges to the Des Plaines River. In the eastern portion of the project, roadway runoff drains to Pump Station 5 and eventually discharges to the South Branch of the Chicago River.

Figure 3-57. Watersheds in the Project Corridor

None of the I-290 existing roadway runoff drains to Addison Creek (Figure 3-57). Land uses for these watersheds are described in Appendix H.

3.7.1.1 Watershed Planning Groups

The proposed project crosses four watersheds represented by watershed groups: The Lower Des Plaines Ecosystem Partnership (LDPEP), The Upper Des Plaines River Ecosystem Partnership (UPDREP), DuPage River Salt Creek Workgroup (DRSCW), and Salt Creek Watershed Network (SCWN). Figure 3-57 depicts the watershed boundaries for the area streams.

The LDPEP (LDPEP, 2004) is an active watershed group consisting of local communities, forest preserve districts, and environmental organizations that work together to identify stressors to the aquatic environment (through stream monitoring) and to develop and implement recommendations and actions to improve water quality and stream health in the watershed.[45] LDPEP is an Ecosystem Partnership associated with the IDNR Conservation 2000 (C2000) Program.[46] This partnership provides watershed resources, assists stakeholders with developing strong grant proposals for watershed improvements, and provides input on the C2000 grant selection process.

The UPDREP was formed to "preserve, protect, and enhance the Upper Des Plaines River Watershed through stakeholder education, collaboration, and technical assistance" (Upper Des Plaines River Ecosystem Partnership, 2015). UPDREP is no longer an active watershed group; however, the information collected by the group is also provided by LDPEP. UPDREP also identified water quality and habitat improvements made by the group in the Watershed Restoration Action Strategy for the Upper Des Plaines River Report. For additional information, refer to: http://lowerdesplaines.org/upper_resources.htm.

The DRSCW is an active watershed group consisting of local communities, publicly owned treatment works (POTW), and environmental organizations that work together to identify stressors to the aquatic environment (through stream monitoring) and develop/implement recommendations and actions to improve water quality and stream health. DRSCW has also identified projects with a high potential to restore beneficial uses to stream segments in the DuPage River-Salt Creek Watersheds. Projects include dam removal, habitat restoration, stormwater management, chloride reduction, and a study of the impact of deicers (Midwest Biodiversity Institute, 2008). For additional information, refer to http://drscw.org/.

The SCWN is an organization that promotes awareness of issues affecting Salt Creek and investigates opportunities to restore the creek to be an enjoyable public resource. SCWN

[45] For additional information, refer to: http://www.upperdesplainesriver.org/ and http://www.lowerdesplaines.org/index.htm.

[46] The C2000 Program (renamed Partners for Conservation in 2008) is a comprehensive, long-term approach to natural resource protection and management in Illinois. The Partners for Conservation program provides funding and technical assistance for habitat restoration, land acquisition, planning, research, and outreach. Partners for Conservation is joint funded by IDNR, IDOA, and IEPA.

conducts public education and outreach throughout the watershed and promotes the use of BMPs to improve water quality and recreation (http://www.saltcreekwatershed.org/).

3.7.1.2 Water Resources

Water resources receiving stormwater flow in the Project Corridor are limited to three streams: Salt Creek, Des Plaines River, and the South Branch of Chicago River. The Des Plaines River and Addison Creek are both crossed by the Project Corridor; however, stormwater does not discharge directly into Addison Creek. Seven stormwater management facilities were also identified in the existing Project Corridor.[47]

The physical, biological, and chemical characteristics of the Project Corridor surface bodies of water are described in the following subsections.

3.7.1.3 Physical and Biological Description of Surface Water Bodies

A stream's physical characteristics (e.g., substrate and flow rate) may affect the aquatic biota. In rivers, habitat is usually closely linked to biological diversity. This subsection describes the physical and biological characteristics of streams crossed by the Project Corridor. The information summarized is primarily based on fieldwork completed as part of the wetland and Waters of the United States (WOUS) delineation conducted for the project (Huff & Huff, 2014) and available data through the Illinois Natural History Survey (INHS), IDNR, and USEPA STORET databases. No stream sampling was conducted as part of this project. Key physical characteristics of the streams are listed in Appendix H.

Flow Characteristics

Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River are streams with flow. In general, a perennial stream usually maintains constant flow throughout the year and is capable of supporting fish and aquatic life. All four streams are perennial (Parsons Brinckerhoff, 2014; CBBEL, 2014).

Stream Substrate

A streambed may be composed of sand, gravel, cobble, detritus, silt, clay, or bedrock. Within the Project Corridor, the substrate of Salt Creek consists of silt and gravel. Addison Creek consists of silt, while the substrate of the Des Plaines River consists of silt, loam, and gravel. The substrate of the South Branch of the Chicago River is composed of silt and muck.

Stream Width and Depth

The Project Corridor streams range in width from approximately 50 to 165 feet, and water depth ranges from approximately 1 to 26 feet.

[47] Section 404 (Clean Water Act) waters are defined at and determined in accordance with 33 CFR §§328-329 and 40 CFR §230.3. Final jurisdictional determination is completed by the USACE.

Riparian Vegetation

Riparian habitat includes the vegetated portion of the floodplain adjacent to rivers, streams, and creeks. Riparian habitat functions may include erosion control, streambank stabilization, water quality benefits, treatment of contaminated stormwater runoff, habitat for plants and animals, a source of organic and nutrient input, moderation of stream temperatures (keep streams cool), and recreational or aesthetic value.

The discharge into Salt Creek occurs adjacent to and on the south side of I-88. Trees and shrubs are located along a narrow riparian corridor in this portion of Salt Creek, which is located in an area of office buildings.

Addison Creek and the Des Plaines River have trees or shrubs located within a relatively narrow riparian corridor. Addison Creek is channelized within the Project Corridor and, for the most part, the beneficial buffer functions of the riparian habitat within the Project Corridor are limited (CBBEL, 2014). Within the Project Corridor, Addison Creek is located immediately adjacent and parallel to the north side of I-290 west of 25th Avenue. The creek banks are stabilized with concrete and vegetation, dominated by box elder *(Acer negundo),* silver maple *(Acer saccharinum),* American elm *(Ulmus americana),* catalpa *(Catalpa speciosa),* riverbank grape *(Vitis riparia),* and mowed turf (Huff & Huff, 2014).

Extensive wooded areas are located adjacent to the Des Plaines River north and south of the Project Corridor. Throughout the Project Corridor, the Des Plaines River has a bed of silty, loamy soil (Parsons Brinckerhoff, 2014). The channel banks are fairly steep and vegetated with grass and trees through most of the reach (Parsons Brinckerhoff, 2014). The upstream natural channel is in fairly good condition in the vicinity of the FAI-290 Bridge; however, the downstream channel banks, especially the east bank of the channel, are very steep and significantly eroded (Parsons Brinckerhoff, 2014).

The South Branch of the Chicago River has man-made concrete retaining walls and flows through a heavily urbanized area; therefore, it has limited riparian vegetation (Pescitelli and Rung, 2009).

Mean Habitat Score

A habitat assessment was not completed for Addison Creek, the Des Plaines River, or the South Branch of the Chicago River. A habitat assessment was completed for Salt Creek by DRSCW in the "Stream Dissolved Oxygen Improvement Feasibility Study for Salt Creek" (HDR, September 2009).

The Illinois Environmental Protection Agency (IEPA) Qualitative Stream Habitat Assessment Procedure (SHAP) was utilized to describe Salt Creek based on the observations collected during the reconnaissance. The SHAP index includes factors for bottom substrate, deposition, substrate stability, canopy cover, pool substrate characterization, pool quality, pool variability, canopy cover, bank vegetation, top of bank land use, flow-related refugia, channel alteration, channel sinuosity, width/depth ratio, and hydrologic diversity. Based on the subjective evaluation for the aforementioned factors, a SHAP score is determined. SHAP scores can range from 15 to

208, with scores above 142 considered excellent, between 100 and 142 considered good, between 59 and 100 considered fair, and lower than 59 considered poor.

A reconnaissance of Salt Creek was completed on October 13, 2005, during a period of low-flow conditions from I-88 to Cermak Road. In this section, Salt Creek is 2.6 feet deep with a mud bottom 2 to 5.9 feet deep with gravel substrates.

The SHAP for this segment was 55 of 208, indicating poor habitat quality. The section had poor habitat diversity, scattered canopy, and was mostly deep pools.

Upstream Drainage Area and Watershed Characteristics

Assessing the upstream drainage area and characteristics of a watershed can provide information relative to stream health and potential causes of impairment. The upstream drainage areas range from approximately 17.1 square miles (Addison Creek) to approximately 480 square miles (Des Plaines River). The Salt Creek drainage area is approximately 102.8 square miles and the South Branch of Chicago River (in natural state) drainage area is 226 square miles (Horton, 1914). Most of the land use in the Project Corridor watersheds includes developed land that likely has contributed to stream degradation.

Highly Erodible Soils

Highly erodible soils have been identified to have slopes of 4 percent or greater. These soils are usually associated with changes in topography and can occur along streams. When cleared of vegetation, these soils can become a source of sediment for adjacent waters. Based on the Cook County soils map, approximately 2 acres of highly erodible soils were identified in the Project Corridor, primarily within residential areas at the western terminus of the Project Corridor. Even though soil types have been mapped by the NRCS, most of the Project Corridor soils have been extensively altered by past grading activity associated with the existing roadway network and adjoining development; therefore, the mapped characteristics actually may not be present.

Biological Stream Ratings

In 2008, IDNR released biological stream ratings for Illinois streams (IDNR-Office of Resource Conservation [ORC], 2008).[48] These ratings can be used to identify aquatic resource quality, including biologically diverse streams and those with a high degree of biological integrity. The diversity and integrity scores fall within one of five ratings, ranging from A to E, with A representing the highest biological integrity or diversity of evaluated stream segments.

The segment of Salt Creek (GL-09) receiving runoff has not been assessed for biological significance, biological integrity, or diversity; however, the segment immediately south (GL-01) has been assessed. Salt Creek segment GL-01 was not considered biologically

[48] Based on information from IDNR, the new stream ratings replace the Biological Stream Characterization and Biologically Significant Stream developed in 1984 and 1992, respectively.

significant, received a diversity rating of B, and received a biological integrity rating of D (IDNR, 2008).

Within the Project Corridor, Addison Creek received an E rating for both biological diversity and integrity (IDNR, 2008). The segment of the Des Plaines River within the Project Corridor has not been assessed by IDNR. The segment of the Des Plaines River downstream of the Project Corridor received a rating of B for diversity and a C rating for integrity (IDNR, 2008).

The South Branch of the Chicago River was assessed as rating D (poor) for biological integrity and diversity, which indicates a limited aquatic resource with almost exclusively tolerant species present (IDNR, 2008).

Fish

Biological data for Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River were obtained from various studies. Appendix H contains a summary of their biological characteristics. Salt Creek data were obtained from DRSCW studies, approximately 3.3 to 5 miles downstream of the Project Corridor (DRSCW, 2007 and 2010). No intolerant species were identified; commonly occurring species include bluntnose minnow *(Pimephales notatus),* white sucker *(catostomus commersoni),* gizzard shad *(dorosoma cepedianum),* bluegill *(lepomis macrochirus),* orange spotted sunfish *(lepomis humilis),* and green sunfish *(lepomis cyanellus).*

In 2010, INHS conducted sampling of Addison Creek approximately 7 miles upstream of the Project Corridor (Wetzel *et al.,* 2010). The studies indicated that Addison Creek had five fish species present; none of these were intolerant species. Fathead minnows *(Pimephales promelas)* were 87 percent of the species collected.

The INHS fish collection database for Cook County contains records of 56 species of fish within the Project Corridor streams (INHS, 2014). Pollution intolerant fish species, threatened or endangered species, or "Species in Greatest Need of Conservation for Illinois"[49] have been collected within the Des Plaines River in Cook County. The bigmouth shiner *(Luxilus cornutus)* is the only Species in Greatest Need of Conservation that has been identified within the Des Plaines River in Cook County in the last 15 years).

The Des Plaines River may be used for recreational fishing, but it does not support commercial fisheries. Game fish, such as largemouth bass *(Micropterus salmoides),* bluegill, sunfish *(Lepomis* spp.), bullhead *(Ameiurus* spp.), and black crappie *(Pomoxis nigromaculatus)* are known to occur within the Des Plaines River in Cook County (INHS, 2014). Largemouth bass are widespread in Illinois and found in habitats of all types and quality.

A study published in 2009, *Fish Surveys in the Lake Michigan Basin 1996-2006: Chicago and Calumet River Sub-basins* by Stephen Pescitelli and Robert Rung, contained biological data for the South Branch of the Chicago River near Van Buren Street, approximately 0.1 mile

[49] Based on Appendix I of Illinois Wildlife Action Plan (IDNR, 2005).

upstream from I-290. A total of 11 different species of fish were identified. The most common, in order, were gizzard shad, bluegill, and spottail shiner *(notropis hudsonius).*

Aquatic Macroinvertebrates

Aquatic macroinvertebrates can be used as indicators of water quality conditions. Available aquatic macroinvertebrates were used to describe area streams and can provide information on water quality. One metric that is commonly used to assess water quality based on the presence of macroinvertebrates is Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies) (EPT) taxa richness, which assesses the species richness present. A score of 0-6 is considered poor, 7-13 fair, 14-20 good-fair, 20-27 good, and greater than 27 is excellent. The Project Corridor streams support aquatic macroinvertebrate communities that are typical of polluted, urban streams, and no listed threatened or endangered species occur within the Project Corridor.

DRSCW collected macroinvertebrates in Salt Creek approximately 3.3 to 5 miles downstream of the Project Corridor. The most commonly occurring macroinvertebrates collected were the non-biting midge *(Polypedilum (P.) illinoense)* and aquatic worms *(Oligochaeta)* (DRSCW, 2007 and 2010). The Metropolitan Water Reclamation District of Greater Chicago (MWRDGC) also conducted macroinvertebrate surveys approximately 13 miles upstream, near Devon Avenue, in 2010 using two different collection methodologies. The most commonly occurring macroinvertebrates were segmented worms *(Oligochaeta),* flatworms *(Turbellaria),* caddisflies *(Cheumatopsyche)* and midges *(Tanytarsus).* EPT taxa richness was also provided for the results of the Hester-Dendy sampling method and Petite Ponar sampling method. Both methods had an EPT taxa richness score of 3, which is considered poor (MWRDGC, 2012).

Based on the results of an unrelated study, a section of Addison Creek, 7 miles upstream of the Project Corridor, had relatively tolerant macroinvertebrate communities, with scores associated with impaired water quality (Midwest Biodiversity Institute, 2008). A 2010 study conducted at the same Addison Creek location also showed a high incidence of tolerant macroinvertebrates and had a low EPT taxa richness score of 0, which is considered poor (Wetzel *et. al,* 2010).

MWRDGC collected macroinvertebrates in the Des Plaines River approximately 6 miles downstream of the Project Corridor near Ogden Avenue. The most commonly occurring macroinvertebrates were segmented worms, non-biting fly (*Polypedilum scalaenum grp)*, non-biting midge, caddisflies, and midges in the Des Plaines River. Two sampling methods were used – Hester-Dendy and Petite Ponar – and different EPT scores were provided for each method. The EPT taxa richness score was 6 for the Hester-Dendy method and 3 for the Petite Ponar method, and both are considered poor (MWRDGC, 2012).

The South Branch of the Chicago River was also sampled by MWRDGC in 2010 approximately 0.26 mile upstream of the Project Corridor near Madison Street. The most commonly occurring macroinvertebrates were segmented worms and sow bugs *(Caecidotea).* Two sampling methods were used, and EPT taxa richness scores were

provided for each sampling method. The EPT taxa richness score for both the Hester-Dendy and Petite Ponar method was 0, which is considered poor (MWRDGC, 2012).

Mussels and Clams

Available databases were searched for mussel and clam information associated with the Project Corridor streams. Based on available data, 16 species of mussels were collected from Addison Creek and the Des Plaines River in Cook County (INHS, 2014). Most of these mussel species are widespread or common and locally abundant species. Only two species, the flutedshell *(Lasmigona costata)* and ellipse *(Venustaconcha ellipsiformis),* identified within the Des Plaines River in Cook County, are considered pollution intolerant. The flutedshell record is from 2009, and the ellipse record is from 1957.

Mussel data for Salt Creek were obtained from INHS (1997-2009) studies. Based on these studies, three species of mussels were collected from Salt Creek near I-88, including Asiatic clam *(Corbicula fluminea),* which is an introduced species. Additionally, the paper pondshell *(Utterbackia imbecillis)* and the lilliput *(Toxolasma parvum)* were collected, and both are common and widespread species in Illinois. In 2006, a relic shell of the state endangered rainbow mussel *(Villosa iris)* was collected from Salt Creek (near the Cook County border), but no live shell was collected in Cook County.

No mussel surveys were available for the South Branch of the Chicago River.

3.7.1.4 Water Quality

Within Illinois, waters are protected and evaluated under the General Use Water Quality Standards (Title 35 Illinois Administrative Code, Subtitle C, Chapter I, Part 302, Subparts A and B). Designated uses under the General Use Water Quality Standards include aquatic life, fish consumption, primary contact, and aesthetic quality. States are required to classify waters with respect to impairments. Waters that do not fully support their designated uses are considered impaired and are cataloged in the 303(d) list, requiring total maximum daily loads (TMDLs). TMDLs establish pollution reduction goals to improve the quality of impaired waters.

As of July 1, 2015, the South Branch of the Chicago River, as part of the Chicago Area Waterway System, has newly approved water quality standards (Title 35 Illinois Administrative Code, Part 302, Subpart D - Illinois Environmental Protection regulation). The Indigenous Aquatic Life stream use has been replaced with "Chicago Area Waterway System Aquatic Life Use A" standards. The South Branch Chicago River has specific dissolved oxygen and chloride water quality standards. From July 1, 2015 to July 1, 2018, the following applies:

- Chloride: 500 milligrams per liter (mg/L) (May 1 thru November 30);
- Total Dissolved Solids: 1,500 mg/L (December 1 thru April 30); and
- Dissolved Oxygen: minimum of 5.0 mg/L (March thru July); 4.0 mg/L daily minimum average over seven days; and 3.5 mg/L at any time (August thru February).

After July 1, 2018, the water quality standard in effect for chlorides will be 500 mg/L and the Total Dissolved Solids water quality standard will be repealed.

The CAWS Chloride Reduction Initiative Workgroup Chloride Reduction Initiative (which includes IDOT) has requested a 5-year variance from the chloride water quality standard for the South Branch of the Chicago River. This variance would not affect the water quality standards for the Des Plaines River, Addison Creek, or Salt Creek.

TMDLs have been prepared for waters in the Salt Creek Watershed,[50] including Addison Creek (CH2M Hill, 2004). Addison Creek has an approved TMDL for Ammonia-N, carbonaceous biochemical oxygen demand (CBOD), chloride, dissolved oxygen, total dissolved solids, and total suspended solids (TSS). Table 3-40 summarizes the uses, impairment, and causes of impairment for Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River.

Urban streams, such as those crossed by the Project Corridor, often show signs of degradation. The water quality of streams in developed watersheds typically reflects the point and nonpoint source pollutant discharges from surrounding urban areas.

Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River waters do not support aquatic life (i.e., have an aquatic life use impairment), have been channelized or modified, and are surrounded by development (with forest preserve areas generally being an exception). The sources of impairment include combined sewer overflow and urban runoff (IEPA, 2016). Table 3-40 lists all causes and sources of impairments.

The recreational use of Salt Creek, Addison Creek, or the Des Plaines River within the Project Corridor is limited by their degraded nature and water quality impairments (Table 3-40).

Wastewater Treatment Plant Discharges

Effluent from wastewater treatment plants (WWTP) [e.g., municipal point source discharges (MPSD)] can dominate the flow of urban streams, especially during the summer base flow period between July and October (Midwest Biodiversity Institute, 2008). Wastewater effluents entering streams may increase pollutant loads, particularly during low-flow conditions. These loads may affect water quality downstream of their outflows.

[50] The Salt Creek TMDLs address segments of the following Project Corridor creeks: Salt Creek, Addison Creek, Spring Brook, and Meacham Creek (CH2M Hill, 2004a).

Table 3-40. Use Support and Impairment Summary for Project Corridor Water Bodies

Water Body [a]	Designated Use [b]	Causes of Impairment	Sources of Impairment	Impaired Waters [c]
Salt Creek (AUID: GL_09)	Not supporting: AL, FC, PC, Fully supporting AQ, Not assessed: SC	Aldrin, methoxychlor, sedimentation/siltation, TSS, pH, phosphorus (total), mercury, polychlorinated biphenyls (PCBs), fecal coliform, chlorides, dissolved oxygen	Urban runoff/storm sewers, combined sewer overflow, contaminated sediments, private and municipal point source discharge, source unknown, impacts from hydrostructure flow modification/regulation, dam impoundment, upstream impoundment, atmospheric deposition-toxic	Yes
Addison Creek (AUID: GLA_02)	Not supporting: AL, PC, AQ Not assessed: FC, SC	Aldrin, alteration in stream-side or littoral vegetative covers, chloride, chromium (total), DDT, hexachlorobenzene, nickel, other flow regime alterations, phosphorous (total), changes in stream depth and velocity patterns, fecal coliform, debris/floatables/trash	Contaminated sediments, channelization, loss of riparian habitat, combined sewer overflows, MPSD, urban runoff/storm sewers, upstream impoundment, dam or impoundment, municipal (urbanized high-density area)	Yes
Des Plaines River (AUID: G_32)	Not supporting: AL, FC Not assessed: SC, AQ	Chloride, phosphorus (total), mercury, PCBs, fecal coliform	Combined sewer overflows, highway/road/bridge runoff (non-construction related), MPSD, urban runoff/storm sewers, atmospheric depositions – toxics, source unknown	Yes
South Branch of the Chicago River (AUID: HC-01)	Not supporting: Indigenous AL, FC Not assessed: SC, AQ	PCBs, dissolved oxygen, total dissolved solids	Combined sewer overflows, urban runoff/storm sewers, unknown sources	Yes

Source: IEPA, 2016.

[a] Information is provided for water body segment Assessment Unit Identifications (AUID) associated with the Project Corridor. Designated uses and impairments may vary per AUID.

[b] Abbreviations: AL: Aquatic Life; AQ: Aesthetic Quality; FC: Fish Consumption; PC: Primary Contact; SC: Secondary Contact. No specific assessment guidelines have been developed to assess SC use for Illinois streams and inland lakes.

[c] Impairment status is based on the IEPA Illinois Integrated Water Quality Report and Section 303(d) List (IEPA, 2016).

There are no WWTPs within 2 miles of the discharge into Salt Creek (which is at River Mile 14.3) upstream of the Project Corridor. The closest is the Elmhurst WWTP at River Mile 17.8, which is 3.5 miles upstream of the discharge. There are several WWTPs with outfalls to Addison Creek upstream of the Project Corridor. According to the Final TMDL for Salt Creek, there is one point source on Addison Creek upstream of the Project Corridor (Bensenville South STP). There is also a combined sewer overflow (CSO) outfall on Addison Creek, which is near the project area: Bellwood CSO. The South Branch of the Chicago River receives CSOs and urban runoff; however, no WWTPs discharge to the South Branch of the Chicago River. There are no WWTPs on the Des Plaines River within 2 miles of the Project Corridor.

Water Quality Sampling Data

Appendix H contains available water quality monitoring data for Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River. These data were collected from sampling reports of STORET, DRSCW, and MWRDGC. The values in Appendix H represent the range of sampling events conducted by IEPA between 2003 and 2011.

The concentrations of copper, Pb, and zinc achieved the acute General Use Water Quality standards in segments of Salt Creek, Addison Creek, the Des Plaines River, and the South Branch of the Chicago River. The minimum dissolved oxygen values in the three streams achieved the General Use Water Quality Standards.

Based on chloride data from the STORET and MWRDGC database, chloride concentrations in sampled segments of Salt Creek, Addison Creek (GLA_2), and the Des Plaines River (G_39) within the Project Corridor exceeded the 500 mg/L water quality standard for periods of certain winters (IEPA, 2012). IEPA lists chloride as an impairment cause for the segment of the Des Plaines River within the Project Corridor (IEPA, 2016).

The October 2004 *Total Maximum Daily Loads for Salt Creek, Illinois* study for IEPA found that there was one exceedance, out of approximately 46 sample dates, of the chloride standard of 500 mg/L. The exceedance was 867 mg/L on March 11, 1999. The samples were taken at the Salt Creek station (USGS 05531500), which is approximately 6 miles downstream of this project's discharge point into Salt Creek.

Additional information on chloride concentrations in Salt Creek were obtained from the Elgin-O'Hare – West Bypass Study: Tier Two Draft Environmental Impact Statement (2012), which contained a summary of chloride data provided by DRSCW. DRSCW was able to derive chloride concentrations based on conductivity measurements. Three sites were sampled regularly in 2010, and values were presented for the winter months (January through March and November through December) and the remainder of the year (April through October). The nearest two locations were near JFK Boulevard in Addison, which is approximately 7.4 miles upstream, and at Wolf Road in Westchester, which is approximately 5.8 miles downstream. The winter chloride average at JFK Boulevard was 503.4 mg/L, and the winter average for Wolf Road was 576.1 mg/L, exceeding the General Use Water Quality standard.

3.7.2 Environmental Consequences

This subsection discusses potential impacts to surface water resources that would be associated with the construction, operation, and maintenance of the four build alternatives, including the pollutants that could be deposited into receiving waters, potential impacts to water quality, and direct impacts to water resources through construction and the placement of fill material. Pollutants, such as sediments, solids, heavy metals (e.g., copper, Pb, and zinc), oil and grease, deicing material, fertilizers and nutrients, may be released into the environment during construction or may accumulate on roadway surfaces and adjoining rights-of-way as a result of motor vehicle operations and facility maintenance. These pollutants can be transported to receiving waters via stormwater runoff.

3.7.2.1 Construction Impacts to Surface Waters

Each of the four build alternatives would cross two streams, Addison Creek and the Des Plaines River. The construction impacts would be the same for all four build alternatives. Direct impacts to surface waters would result from construction and the placement of fill to construct the proposed improvements. Typical construction activities associated with transportation projects include earthmoving practices (e.g., demolition, clearing and grubbing, grading, filling, excavation) that remove vegetative cover and expose soils. Such activities increase the potential for erosion and sedimentation by exposing disturbed soils to precipitation. The No Build Alternative would not have any construction impacts to the streams.

Increased impervious surface area due to construction and compaction of soils by heavy equipment may result in less stormwater infiltration and additional stormwater runoff. In-stream construction, placement of structures (e.g., abutments and piers), streambank disturbance, channel realignment, and temporary crossings could cause increases in turbidity and sedimentation and temporarily alter downstream hydraulics and substrate conditions. Downstream aquatic systems could be temporarily affected by the increases in turbidity and sedimentation. Increased sedimentation during construction has the potential to cover stream substrate, thereby affecting habitat for some species of fish and macroinvertebrates. The magnitude of impact varies based on several factors, such as proposed type of crossing, number of crossings, stream characteristics (substrate, depth, current velocity), soil type, construction method, and implementation of BMPs.[51]

Highly erodible soils are mapped as being present within the Project Corridor; however, these soils do not occur near the Addison Creek or Des Plaines River crossings.

[51] BMPs are schedules of activities, prohibition of practices, maintenance procedures, and other management practices used to prevent or reduce negative impacts to water quality.

The placement of piers for stream crossings and additional lanes may also have an impact on surface waters. Table 3-41 summarizes the proposed improvements to piers and bridges at the stream crossings and incremental loss of stream bed due to these improvements. As such, surface water impacts are associated with the widening or lengthening of existing piers and ancillary areas to support stream crossing structures.

Table 3-41. Streams Crossed by the Proposed Project in the Existing and Build Condition

Stream [a]	Incremental Permanent Impacts to WOUS (acres)	Temporary Impacts to WOUS (acres)	Description of Existing Crossing and Stream Bed Loss	Description of Proposed Crossing and Stream Bed Loss
Addison Creek	0.22	0.31	Open abutment bridge with two piers, 2 feet and 6 inches wide by 131 feet, or 0.015 acre.	Piers to be replaced with two piers, 3 feet wide by 206.5 feet long, plus a rectangular area on each abutment 20 feet wide by 225 feet long, or 0.24 acre.
Des Plaines River	0.18	0.25	One pier 4' on one end of pier and 5.9' on other end of pier, by 104 feet, located near the center of the channel, or 0.007 acre.	Bridge would be replaced. One existing pier in the center would be replaced with two piers, 4 feet wide by 144 feet long, plus a rectangular area on each abutment 20 feet wide by 175 feet long, on either side of the channel, or 0.19 acre.

[a.] No stream crossings within the Salt Creek or South Branch of the Chicago River watersheds are proposed.

Within the Project Corridor, Addison Creek is channelized and located immediately adjacent and parallel to the north side of I-290 west of 25th Avenue. The bridge over Addison Creek would be replaced to accommodate two additional lanes, approximately 25 to 30 feet, to support the wider bridge, piers may be replaced or widened. The stream bank of Addison Creek would be reduced at this crossing.

The bridge over the Des Plaines River would also be replaced to accommodate two additional lanes. To accommodate this widening, additional embankment would be required. One pier in the Des Plaines River will be replaced with two piers. No physical changes would occur in Salt Creek or the South Branch of the Chicago River.

With the implementation of BMPs during construction, any proposed in-stream work and construction activities adjacent to the streams would not be expected to adversely impact the overall habitat quality of the stream. Construction-related impacts to the aquatic community are anticipated to be minor and temporary in nature.

3.7.2.2 Operational Impacts to Surface Waters

Operations include use of the transportation system. Potential impacts associated with operation of any of the build alternatives would result from pollutant accumulation on roadway surfaces, median areas, and adjacent rights-of-way. Pollutants accumulate through use of the transportation system, natural processes, and as a result of airborne deposition. Pollutant concentrations are highly variable and are affected by numerous factors, such as traffic characteristics (volume and speed), weather (precipitation and wind), maintenance practices, and adjacent land uses. Primary constituents of highway runoff associated with typical operations include TSS (from pavement wear, atmospheric deposition, dirt), Pb (from tire wear), zinc (from tire wear, motor oil, grease), copper (from metal plating, moving engine parts, brake lining wear), and petroleum (from spills, leaks, gasoline, antifreeze, hydraulic fluids). Roadway runoff can transport pollutants that have accumulated on impervious surfaces of the roadway to adjacent streams.

Additional travel lanes and other impervious surfaces would be constructed under each build alternative. As the impervious area of a roadway increases, the volume of stormwater runoff increases and stormwater infiltration decreases. Use of the additional impervious surfaces would generate more pollutants. The section of the Project Corridor that is associated with the Salt Creek subwatershed is from the western project terminus near Butterfield Road to Wolf Road. In the Salt Creek section of the Project Corridor, the build alternatives would result in a small increase in lane-miles compared to the No Build Alternative due to an additional lane being added at the I-290/I-88 system interchange (eastbound I-88 to eastbound I-290); this change would represent less than 1 percent growth in lane-miles. A slight shift in the mainline lanes is also proposed in the Salt Creek section for the build alternatives, but this would have minimal effect on lane-mile totals.

Stormwater runoff from the Project Corridor is managed through a series of pump stations. As a result, the watershed boundaries do not reflect the discharge points for the Project Corridor.

As shown in Table 3-42, the Des Plaines River is receiving more than 63 percent of the stormwater runoff from the Project Corridor.

The Des Plaines River receives stormwater from two sections of the Project Corridor:

1. One section from Wolf Road east to the Des Plaines River; and
2. One Section from Central Avenue west to the Des Plaines River.

Table 3-42. Watersheds Receiving Project Corridor Stormwater

Watershed	Length of I-290 in Watershed (miles)	Percent	Length of I-290 Runoff Reaching Stream (miles)	Percent
Salt Creek	0	0	1.5	14
Addison Creek	3.4	32	0	0
Des Plaines River	2.1	20	6.7	63
Chicago Ship & Sanitary Canal	3.9	37	0	0
South Branch Chicago River	1.2	11	2.4	23
TOTAL:	10.6	100	10.6	100

These two sections of the build alternatives would each have an estimated 24 percent increase in mainline lane-miles compared to the No Build Alternative due to an added through lane in each direction. The Des Plaines River would also receive stormwater runoff from a proposed sewer system along the frontage roads from 25th Avenue to 1st Avenue, parallel to Harrison Street and Bataan Drive. The proposed storm sewer system along the frontage roads reduces the occurrence of combined sewer overflows (CSO) in the Village of Maywood. A new Outlet #4 to the Des Plaines River is proposed to separate ComEd stormwater runoff from Pump Station 4. The outlet is needed for hydraulic purposes, and will require approximately 10 feet of permanent easement under an existing parking lot at the Circuit Court of Cook County Fourth Municipal District Maywood Courthouse. This change will not result in additional impervious area (Sheet 6 of Section 3.0 Map Set). Refer to Section 3.9.2.1 for further description of Addison Creek characteristics and the ongoing MWRDGC Addison Creek Reservoir and Channel Improvements projects

The section of the Project Corridor associated with the South Branch of the Chicago River subwatershed is from Central Avenue to the eastern project terminus at Racine Avenue. The build alternatives in this section of the Project Corridor would have no proposed changes to the mainline that would result in appreciable changes in lane-miles; however, the slope of this section of the mainline is being adjusted, which would have a slight effect on the runoff volume.

Water impacts are site-specific and depend heavily on the characteristics of the highway and the receiving waters. The degree of pollutant loading is linked directly to the amount of roadway traffic. Research indicates few substantial impacts from highways with ADT that is less than 30,000 vpd (Young *et al.*, 1996; Dupuis *et al.*, 1985). Under these conditions, potential impacts are generally short term, localized, acute loadings from temporary water quality degradation, with few (if any) long-term or chronic effects.

All projected year 2040 ADTs (bidirectional) of the build alternatives exceed 30,000 vpd. The projected bidirectional ADTs for the four build alternatives in the year 2040 range from 151,000 to 240,200 vpd.

For Addison Creek and the South Branch of the Chicago River, no change in pollutant concentrations would occur. Addison Creek receives no runoff and the existing drainage to the South Branch of the Chicago River is unchanged from existing to the No Build and build condition.

Runoff from I-290 to Salt Creek would increase by less than 1 percent. The increase is associated with changes in ramp pavement. The resulting change in pollutant concentration in Salt Creek did not result in a measurable increase.

Pollutant concentrations in the Des Plaines River were evaluated using the Stochastic Empirical Loading and Dilution Model (SELDM) (Granato, 2013). This model was recently developed by USGS to provide a planning-level estimate of pollutant concentrations. SELDM performs a Monte Carlo analysis in which the precipitation, pre-storm flow, runoff coefficients, and concentrations of water quality constituents in highway runoff are varied randomly within defined probability distributions. SELDM was used to predict the potential effect of highway runoff on pollutant concentrations in the Des Plaines River.

The SELDM pollutant loading analysis evaluated the predicted once-in-3-year water quality concentration of four common roadway pollutants and compared the values to the acute water quality standards. Detention basins planned at Mannheim Road and 25th Avenue also provide reduction of these pollutants in the build scenario. There were no predicted water quality exceedances for Pb, copper, or zinc for the build alternatives. There is no water quality standard for TSS; however, reduction of TSS provides water quality benefits.

Appendix H contains the calculations for pollutant reductions based on the BMP concept applied. Section 3.7.3.2 describes the evaluation of BMPs.

The proposed detention basins, where constructed, would reduce pollutant loadings in the Des Plaines River, as that is the only stream where a detention basin could be constructed due to space constraints. Section 3.7.3 describes the evaluation of BMP measures within the site-specific constraints of the Project Corridor. Based on the pollutant loading analysis, concentrations achieved the Illinois General Use Water Quality standards for all streams.

3.7.2.3 Maintenance Impacts to Surface Waters

Maintenance impacts associated with the build alternatives would include implementation of deicing practices during winter months and herbicide spraying for invasive/noxious vegetative species within the right-of-way. Herbicide applications would follow the manufacturer's guidelines to minimize drift and runoff into surface waters. An NPDES permit for pesticide application point source discharges, including herbicide application, would be obtained, as necessary.

Seasonal deicing with salt (commonly sodium chloride), along with plowing and other alternative measures, are used to reduce snow and ice build-up on roads. Deicing assists with safe traffic movement by improving road conditions in winter, but application of road salt contributes chloride loads to surface waters. Road salt is highly soluble and moves through the environment in solution as runoff, splash, spray, and dust. The

potential impact that stormwater containing chlorides may have on receiving waters is dependent on many factors, such as the concentration, size of the water body (water volume), precipitation, topography, soil type, and drainage patterns.

The General Use Water Quality Standard for chloride for Salt Creek and the Des Plaines River is 500 mg/L. For the South Branch of the Chicago River, a standard of 500 mg/L of chloride applies May 1 through November 30.[52] From December 1 through April 30, a Total Dissolved Standard of 1,500 mg/L will apply from 2015 to July 1, 2018. After July 1, 2018, the water quality standard for chlorides will be 500 mg/L year-round.

Currently, IDOT is participating in the CAWS Chloride Reduction Initiative. This work group is preparing a variance to address these new standards considering reduction of salt usage in the CAWS using BMPs.

The primary methods of snow and ice removal in IDOT, District One, are plowing and the application of road salt. During 10 winter seasons (2000/2001 through 2010/2011), IDOT averaged 21.7 tons of salt per lane-mile (system wide).[53] Efforts are made to apply only the amount of material necessary to maintain motorist safety. The total quantity of road salt entering the environment varies based on the number of snow events per season and the number of times road salt is applied per storm.

Each build alternative would increase the number of lane-miles and pavement in the Project Corridor, thereby increasing the total salt loading over existing levels. Potential water quality impacts to the Project Corridor streams due to chlorides were evaluated for the build alternatives using the USGS methodology developed by Frost, Pollock, and Wakelee (1981) for existing and build conditions (Table 3-43).

The incremental daily average chloride concentration contribution of the existing roadway to area streams ranges from 1.7 mg/L to 4.2 mg/L. With the proposed improvements and increased lanes, the average chloride concentration would incrementally increase to a range of 2.5 mg/L to 4.4 mg/L. The small incremental change in concentration is attributed to the large drainage area and stream flow compared to the volume of I-290 runoff. No change (less than 0.1 percent) is estimated for Salt Creek because only 0.1 lane-mile is being added in the build alternatives; the chloride loading to the South Branch of the Chicago River would also remain the same because roadway runoff volumes would not increase as a result of the project. Though there would be no change in chloride load, a slight increase in annual daily average concentration was predicted for the South Branch of the Chicago River due to the change in slope associated with the build alternatives. The Des Plaines River is the primary stream where chloride loadings would increase by 59 percent, with increased annual daily average concentration from 1.7 mg/L to 2.5 mg/L.

[52] Title 35 Illinois Administrative Code, Subtitle C, Chapter 1, Part 302.

[53] Salt application rates are based on information from IDOT.

Table 3-43. Incremental Chloride Contribution Analysis

Stream	Highway Lane-Miles			Annual Daily Average Chloride (mg/L)			Annual Daily Maximum Chloride (mg/L)		
	Existing/ No Build	Build	Percent Increase	Existing/ No Build	Build	Percent Increase	Existing/ No Build	Build	Percent Increase
Salt Creek[1]	12.3	12.4	0.9	2.9	2.9	0.6	30	30	>0.1
Des Plaines River [2,3]	37.0	**57.6**	**55**	1.7	**2.5**	**48**	29	**30**	**5**
South Branch of Chicago River [4]	44.7	44.7	0.0	4.2	4.4	4	33	33	0.0

[1] Stormwater runoff drains from the western limits of the project (I-290) to station 70+00 (about even with the CarMax) drains to Pump Station 20, then into Salt Creek at I-88 near York Road.

[2] Stormwater runoff drains from station 70+00 to the east (drains into main trunk sewer that passes under Addison Creek draining into Pump Station 4 and then into Des Plaines River).

[3] Stormwater runoff drains from Central Avenue to the west of Des Plaines River drains to Pump Station 4 and discharges to the Des Plaines River.

[4] Stormwater runoff drains from Central Avenue to the eastern project limits flows into Pump Station 5, which then discharges into the South Branch of the Chicago River.

The annual daily maximum chloride concentration contribution ranges from 29 mg/L to 33 mg/L in the existing condition, while the build chloride contribution ranges from 30 mg/L to 33 mg/L. Annual daily maximum chloride concentrations in Salt Creek and the South Branch of the Chicago River would not increase as a result of this project. There would be an increase in chloride loading to the Des Plaines River associated with the build alternatives. Given the chloride impairment of the Des Plaines River, IDOT would use BMPs to offset the potential increase to the Des Plaines River, as discussed in Section 3.7.3.

3.7.3 Measures to Minimize Harm and Mitigation

3.7.3.1 Construction Impacts

To reduce potential stream impacts, soil erosion and sediment control measures near streams would involve special consideration, such as minimization of soil disturbance, installation of applicable soil erosion and sediment controls prior to, during, and following construction. This may include installation of silt fence prior to construction activities, installation of temporary erosion control products if disturbed areas are to sit idle, and protection of side slopes with seed and rolled erosion control products (i.e., erosion control blanket) to assist with vegetation establishment.

In-stream construction may be required to replace or widen bridge piers, widen bridges, extend culverts, and install new culverts near the proposed detention basins. In-stream construction would follow standard practice (IDOT *Standard Specification for Road and Bridge Construction* [IDOT, 2012]), including isolating the work area, as necessary. All required permits and approvals (e.g., Section 404 CWA, Section 401 CWA water quality certification, and IDNR-OWR floodway construction permits) would be obtained prior to any in-stream construction. Mitigation for WOUS will be provided for a ratio of 1:1. Additional details regarding construction methodology would be provided during CWA and floodway construction permitting.

Flow would be maintained during construction in Addison Creek and the Des Plaines River by using dam and pumping, fluming, culverts, or other techniques. Cofferdams, if necessary, would be constructed of non-erodible materials; earthen embankments or dikes would not be used as cofferdams. If dewatering is required to perform "work in the dry" in perennial streams, the dewatering would be temporary in nature. All materials used for temporary construction activities would be moved to upland areas following completion of the construction activity. Temporarily disturbed areas would be restored to preconstruction conditions, including grading to original contours and installation of erosion control as soon as practicable in accordance with NPDES permit requirements. Erosion and sediment controls would be used to minimize downstream impacts. Further discussion of construction impacts related to water resources is discussed in Section 3.14, Construction Impacts.

3.7.3.2 Operational Impact Practices

Stormwater would be managed through a combination of stormwater runoff, drainage collection facilities, and post-construction BMPs. The three streams receiving stormwater discharges have impaired water quality due to various pollutants and conditions. The only pollutant identified as a cause of impairment and associated with roadway operations is chloride. For both Salt Creek and the Des Plaines River, chloride has been identified as a potential water quality concern. Section 3.7.2.3 describes maintenance impacts to surface waters.

The feasibility of BMPs for the build alternative was evaluated given the physical site constraints of the Project Corridor. Limited right-of-way space, low permeable soils, and drainage patterns all affected the potential options for stormwater treatment.

An existing detention basin is located near Pump Station 20, which currently treats 2 percent of stormwater runoff from the existing roadway prior to discharging into the Salt Creek. Four additional detention basins are proposed in the Project Corridor along Mannheim Road and 25th Avenue. The proposed detention basins would treat an additional 11 percent of stormwater runoff from the Project Corridor prior to discharging into the Des Plaines River.

There are currently no existing detention basins to treat metals and TSS in stormwater prior to discharging to the South Branch of the Chicago River. An underground vault is proposed at Kostner Avenue that drains to the Pump Station 5 outlet to the South Branch of the Chicago River. This vault is needed for hydraulic reasons, to supplement the existing underground trunk sewer that is in need of additional capacity. There is no increase in stormwater directed to the South Branch of the Chicago River due to the project and an expected increase of only 0.1 percent to Salt Creek.

Several BMPs were evaluated for implementation. This included infiltration, permeable pavement, green side street features, and rain gardens. Permeable pavement on the shoulders was considered; however, maintenance of these shoulders on a high traffic volume corridor reduced their feasibility. Green side street features include rain gardens and native buffers. These features provide potential reduction of stormwater runoff along the frontage roads and adjacent side streets. Opportunities for including these features will continue to be evaluated; however, no reduction in runoff volume or quality was considered in determining potential water quality impacts. Three locations at 1st Avenue, Harlem Avenue, and Austin Avenue were evaluated for infiltration features. The soils in these areas had low permeability, which reduced the feasibility of potential implementation. Rain gardens were considered where excess land and drainage patterns provide an opportunity for construction.

3.7.3.3 Deicing

Even though chloride is dissolved in the stormwater runoff, the daily annual maximum chloride concentration may be reduced by using structural BMPs. BMPs, such as detention ponds, attenuate the peak concentration of stormwater flows by mixing chlorides with permanent pool volumes in existing wet ponds and/or by collecting the

runoff and allowing it to mix with lower-concentration runoff. For the Des Plaines River, four detention basins are being constructed, which should have a beneficial effect on the maximum chloride concentrations discharged to the river. In addition, nonstructural BMPs (e.g., pre-wetting and monitoring salt application rates) are already used and will continue to be used to balance public safety and environmental impacts.

The amount of salt entering the environment depends on the number of snow storms per season and salting events per storm. There will be additional effort applied to identify ways for the proposed project to achieve lower chloride concentrations in receiving streams through the implementation of stormwater BMPs, promoting deicing material application best practices in the Project Corridor watersheds, reviewing the anticipated road-salt application rate for future operating conditions, and evaluating chloride reduction implementation plans for TMDLs developed within the watersheds affected by the project. IDOT recognizes that water quality is an important issue and will strive to meet chloride standards based on prudent and practicable stormwater and road salting BMPs to the extent that public safety is not compromised.

3.8 Groundwater

There have been no substantive changes to this section since publication of the DEIS.

This section discusses the groundwater resources that are found within the Project Corridor. The potential impacts to these resources from each of the build alternatives are presented, along with measures to minimize or mitigate potential impacts.

3.8.1 Affected Environment

Groundwater resources in the Project Corridor occur below surficial deposits of permeable bedrock, sand, gravel, silt, and/or clay. According to the Berg map, which assesses "potential for contamination of shallow aquifers from land burial of wastes" (Berg *et al.*, 1984), the Project Corridor lies within Zones AX, A1, B1, C1, and E. Zone AX is described as alluvium containing a mixture of gravel, sand, silt, and clay along streams and variable in composition and thickness. Zone A1 is described as permeable bedrock at or within 20 feet of the surface with variable underlying materials. Zone B1 is described as sand and gravel less than 20 feet thick over relatively impermeable till or bedrock. Zone C1 is described as permeable within 20 to 50 feet of the surface overlain by till or other fine-grained material. Zone E is described as uniform, relatively impermeable silty or clayey till at least 50 feet thick with no evidence of interbedded sand and gravel. Zones AX, A1, and B1 represent a high potential for aquifer contamination.

USEPA regulates potential impacts to sole source aquifers. According to EPA's list of designated sole source aquifers, there are no sole source aquifers, as defined by Section 1424(E) of the Safe Drinking Water Act, within the Project Corridor. In addition, there are no Karst formations in the Project Corridor.

The Project Corridor contains no Class III special resource groundwaters. Such groundwaters are determined by the Illinois Pollution Control Board to be demonstrably unique or irreplaceable sources of groundwater and are suitable for application of a water quality standard more stringent than Class I groundwater. Class III groundwaters are considered vital contributors for particularly sensitive ecological systems and/or dedicated nature preserves.

Drinking water in the Villages of Bellwood, Broadview, Forest Park, Hillside, Maywood, Oak Park, and Westchester, and the City of Chicago, is obtained from Lake Michigan. The Village of Bellwood operates three backup wells.

To help protect drinking water supplies, the Safe Drinking Water Act was amended in 1986 to require states to develop wellhead protection areas. Wellhead protection areas represent surface and subsurface areas surrounding a community water supply (CWS) well through which contaminants have the potential to move toward the well system. Typically, wellhead protection areas are assumed to extend 1,000 feet from the well; however, local geography may extend these areas if potential for contamination exists in a larger area. In addition to wellhead protection areas, individual wells have setback

zones, typically 200 to 400 feet, which represent the area from which the well draws water. There are no CWS or Non-CWS setback zones within the Project Corridor.

Private water well information was obtained from the Illinois State Geological Survey (ISGS) water well database. Only one private well (API 120310277600) was identified in the ISGS database located within the Project Corridor. This well is located in the northwest quadrant of the 1st Avenue overpass bridge, north of the westbound I-290 mainline lanes. The private well was completed in 1947 and finished at a depth of 372 feet. During a field visit, this well could not be located. This well is located within the footprint of the existing expressway construction area and could not be located in the field. No further record has been found regarding this well, so it is assumed that it was removed during construction of this section of the expressway and is no longer in operation.

3.8.2 Environmental Consequences

No impacts to public water supplies are anticipated with implementation of any of the build alternatives. There are no sole source designated aquifers in the Project Corridor; therefore, there are no impacts to sole source aquifers. No measurable change to the available water supply is expected from the proposed improvements. The additional impervious area represents a small reduction in recharge area.

The potential for contamination of groundwater supply wells is determined by proximity to sources, well construction, geological conditions, and management of stormwater. The Illinois Groundwater Protection Act (Chapter 415 Illinois Compiled Statutes Section 55) establishes setback zones for the location of potential sources of pollution, such as underground storage tanks (USTs) and stockpiles of deicing chemicals. Setback zones would be considered in the siting of maintenance facilities and in the operation of dry wells; however, no maintenance facilities are planned for the project. The maximum setback zone around a CWS well is 1,000 feet for protection of groundwater and 200 feet for private wells.

There are no CWS wells within 1,000 feet of the build alternatives. The aforementioned private well located within the Project Corridor at 1st Avenue would be impacted by all of the build alternatives. This private well is likely not currently utilized because the Village of Maywood obtains drinking water from Lake Michigan; it is anticipated the well, if it exists and its location has been confirmed, would be plugged as part of any build alternative and would be closed following well closure procedures as outlined in Section 9 of the Illinois Water Well Construction Code Law (415 ILCS 30/9). It is not anticipated that the well would need to be replaced.

None of the build alternatives create any potential new "routes" for groundwater pollution movement or any new "sources," as defined in the Illinois Environmental Protection Act (415 ILCS 5/3, *et seq.).* Groundwater quality is not expected to be measurably affected by any of the build alternatives.

3.8.3 Measures to Minimize Harm and Mitigation

To minimize potential changes in groundwater quality, post-construction BMPs, such as vegetated swales, native vegetation, filter strips, and stormwater management facilities, will be installed where practical and feasible to collect, detain, and filter stormwater runoff to minimize potential surface and groundwater degradation (Section 3.7). The potential for groundwater infiltration is limited due to the clayey soils; therefore, it is expected that the potential for groundwater migration of contaminants will be minimal.

Detention areas will be created adjacent to the 25th Avenue interchange which will allow for groundwater infiltration. In addition, proposed retaining walls adjacent to the mainline would be being used to create flat grassed areas at the frontage road level. These flat areas will reduce runoff rates and amounts by replacing sloped embankments.

3.9 Floodplains

Since publication of the DEIS, the following substantive changes to this section have been made:

- Updated results from the hydraulic model were included throughout the section with revised fill volumes in floodways and floodplains. The proposed structures would not increase the created water elevation more than 0.1 foot over the natural condition;
- In Section 3.9.1.1, the project description for the proposed Addison Creek Reservoir was updated to reflect its current schedule and status;
- In Section 3.9.1.1, the project description for the proposed Addison Creek channel improvements was updated to reflect its current schedule and status;
- In Section 3.9.2.1, a brief description of MWRDGC and IDOT coordination was added with respect to the Addison Creek Reservoir and Addison Creek Channel Improvements; and
- Added a note to Figure 3-58 in Section 3.9.2.3 stating that the proposed outlet pipe from 1st Avenue to the Des Plaines River would be constructed to hold the 10-year flood frequency.

3.9.1 Affected Environment

According to the National Flood Insurance Program (NFIP) Flood Insurance Rate Maps (FIRMs) produced by the Federal Emergency Management Agency (FEMA), the Project Corridor includes two base floodplains with regulatory floodways (Table 3-44). The Project Corridor is within Cook County. The two base floodplains with regulatory floodways are associated with Addison Creek and the Des Plaines River. The extent of floodway limits were identified from FIRM maps published by FEMA (2015). Bridge or culvert replacement in a designated floodway shall not result in an increase of upstream flood stages more than 0.1 foot over the existing conditions for all flood events up to and including the 100-year frequency flood event if the existing bridge or culvert is not a source of flood damage.

IDOT will follow IDNR-OWR Part 3708 rules for appropriate uses in the Addison Creek and Des Plaines River designated floodways.

Table 3-44. Designated 100-Year Floodplains within the Project Corridor

Waterway[a]	County	Floodplain Area in Project Corridor (acres)[b]	Floodway Identified	Map Set Sheet #
Addison Creek	Cook	64.14	Yes	Sheet 3 of 16
Des Plaines River	Cook	0.94	Yes	Sheet 6 of 16

Source: FEMA, digital version of FIRMs, https://msc.fema.gov/portal (FIRM 17031C04770, 17031CO388J, 17031C0476J, 17031C0389J, 17031C0369J, 17031C0418J, 17031C0506J, 17031C0415J, 17031C0505J, 17031C0395J, 17031C0485J)

[a] All streams and associated 100-year floodplains lie within the Des Plaines River drainage basin (HUC 07120004). This table lists FEMA-named streams and tributaries with mapped floodplain in the Project Corridor.

[b] Area is based on geographic information system (GIS) calculation of digitized published FEMA floodplain data, including right-of-way.

3.9.1.1 Reservoirs

Reservoirs aid to control floods. The existing reservoirs in the Addison Creek watershed and Main Stem of the Lower Des Plaines River subwatershed are described below.

Five flood-control reservoirs exist in the Addison Creek watershed and within Cook County; however, all are located outside of the Project Corridor. The hydraulic effects of these reservoirs are included in the current Addison Creek hydraulic modeling (MWRDGC, 2011). MWRDGC proposed a new 600 acre-foot reservoir in the Addison Creek watershed, approximately 0.75 mile upstream of the Project Corridor. The reservoir is planned to be located northwest of the intersection of Washington Boulevard and 25th Avenue. The proposed reservoir would be approximately 50 feet deep, accessed by a side-channel spillway, and dewatered by a proposed pump station. The reservoir is in the final design phase and is expected to be completed in three years (estimated completion 2020).

The proposed reservoir (in conjunction with proposed Addison Creek channel conveyance improvements and proposed removal of three existing bridges over Addison Creek at 30th, 31st, and 32nd avenues) is expected to attenuate flow in the downstream Villages of Bellwood and Westchester. The boundary between these two villages is the Project Corridor. At I-290 near 30th Avenue, the difference in 100-year water surface elevation (WSEL) with the improvements is minimal as compared to the 2011 MWRDGC model. However, the MWRDGC reduction in 100-year WSEL at I-290 is approximately two feet as compared to the regulatory Flood Insurance Study (FIS) 100-year WSEL. The WSEL differences do not significantly affect the design of the proposed I-290 roadway profile or bridge structure over Addison Creek, but have been accounted for in the plans. The channel improvements are in their final design phase and are expected to be completed in four years (estimated completion 2021).

There are no flood control reservoirs within the Mainstem Lower Des Plaines River subwatershed (MWRDGC, 2011).

3.9.1.2 Spillways and Pump Stations

In addition to the proposed future side-channel spillway and pump station associated with the MWRDGC Project, the following spillways and pump stations are associated with the proposed Project Corridor:

- Under the existing condition, Addison Creek bends to the west and then south in the area north of Harrison Street between Eastern Avenue and Cernan Drive in the Village of Bellwood. Near these bends, Addison Creek can exceed the capacity and flow into I-290 overflows southeasterly toward the 25th Avenue underpass south of Harrison Street. Runoff draining to the 25th Avenue I-290 underpass drains by gravity easterly to IDOT Pump Station 4 to the Des Plaines River.
- The far western portion of the proposed Project Corridor drains into IDOT Pump Station 20, which discharges via storm sewer that follows the Reagan Memorial Tollway (I-88) to Salt Creek.
- The portion of the proposed Project Corridor, east of Central Avenue in the City of Chicago, drains into IDOT Pump Station 5, which discharges into the South Branch of the Chicago River. This pump station is interconnected with IDOT Pump Station 26. When Pump Station 5 reaches capacity, additional inflow to the station overflows to Pump Station 26.
- IDOT Pump Station 26 also discharges into the South Branch of the Chicago River near Jackson Boulevard.

3.9.1.3 Natural and Beneficial Floodplain Values

Beneficial values of floodplains include, but are not limited to, the moderation of floods, water quality, groundwater recharge, fish and wildlife habitat, open space, and recreational value. Both of the floodplains for this project are located in urban areas. Des Plaines River floodplain areas near the Project Corridor are confined within the channel banks, while other floodplain areas upstream and downstream of the corridor spread out over open land, such as the Concordia and Forest Home cemeteries. The Addison Creek floodplain extends across developed residential areas upstream and downstream of the Project Corridor. This floodplain contains homes, industrial buildings, and other structures that experience repeated flood damage.

3.9.1.4 Flood Buyout Properties

Although there are areas of chronic floodplain flooding within and surrounding the Project Corridor, there are currently no properties, communities, local agencies, or counties participating in the FEMA Hazard Mitigation or Flood Mitigation Assistance grant programs or flood-prone property buyout program.

3.9.2 Environmental Consequences

3.9.2.1 Floodplain Encroachments

The floodplain encroachment evaluation was conducted in accordance with EO 11988 "Floodplain Management," "Environmental Documentation for Floodplain Encroachments" as contained in the IDOT *BDE Manual* (IDOT, 2010), "Floodplain

Encroachments" as contained in the IDOT *Drainage Manual* (IDOT, 2011), and Illinois Administrative Code Part 3708 "Floodway Construction in Northeastern Illinois." Guidance from MWRDGC and the various local municipalities was considered in determining floodplain impacts and compensatory storage requirements because the local floodplain ordinances are more restrictive than IDOT requirements.

IDNR requires a 1:1 ratio of compensatory storage volume to fill volume in designated regulatory floodways under the Part 3708 rules.

IDOT considers local floodplain ordinance requirements for compensatory storage after a floodplain encroachment evaluation. The local ordinance that would have jurisdiction for the Project Corridor is the MWRDGC *Watershed Management Ordinance* (WMO), as amended July 10, 2014. Compensatory storage for fill in the floodplain fringe is not mandatory.

The floodplain encroachment evaluation identified potential floodplain encroachments by overlaying proposed roadway locations onto FIRMs published by FEMA (2015). Normal, 10-year, and 100-year natural water surface elevations (WSELs) developed in Existing Conditions Hydraulic Reports were used in conjunction with the proposed roadway cross sections to calculate the amount of proposed roadway fill volume (acre-feet) in the floodplain.

Table 3-45 summarizes the proposed fill within the FEMA mapped floodplains in the Project Corridor.

Table 3-45. Proposed 100-Year Floodplain Fringe Impact Summary

Waterway	Location and Description	Normal to 10 Years	10 to 100 Years
		Cut Volume (acre-feet)	Cut Volume (acre-feet)
Addison Creek	At I-290. Two 3-span bridges with piers to be widened or replaced.	17.07	-4.36
Des Plaines River	At I-290. Two 3-span bridges with center pier to be replaced with two new piers.	0.0	0.00

Table 3-46 summarizes floodplain encroachment type (e.g., longitudinal or transverse).

Table 3-46. Proposed 100-Year Floodplain and Regulatory Floodway Encroachment Summary

Waterway	Crossing Location	Floodplain Encroachment	Floodway Encroachment
Addison Creek	At I-290	Transverse / Longitudinal	Transverse / Longitudinal
Des Plaines River	At I-290	Transverse	Transverse
Transverse Encroachment: Across the floodplain, such as a bridge. Perpendicular crossings are preferable over skewed crossings to minimize floodplain impacts. Longitudinal Encroachment: Along the floodplain, sometimes also called "latitudinal." A reasonable attempt should be made to avoid longitudinal encroachments.			

Transverse encroachments occur when the roadway crosses the floodplain. Transverse encroachments would be unavoidable because the Project Corridor generally runs from east to west while Addison Creek and the Des Plaines River generally run from north to south. The potential transverse encroachments would be generally associated with proposed pavement widening that increases embankment fill in the floodplain and causes culvert extensions or bridge widening.

Longitudinal encroachments occur where the roadway would roughly run parallel to and within the floodplain. This occurs along I-290 and Harrison Avenue, where Addison Creek runs from east to west for several blocks, parallel to the roadway corridor. The addition of pavement and embankment slope would cause a longitudinal encroachment on Addison Creek in this area. The Addison Creek FEMA regulatory floodplain also extends along I-290 west to the Mannheim Road intersection and east past the 25th Avenue underpass.

MWRDGC has been working with IDOT on the Addison Creek Flood Control project, consisting of a reservoir, channel improvements, and removal of the upstream bridges. IDOT and MWRDGC staff met during MWRDGC's preliminary design phase, and more recently on July 26, 2016. Hey and Associates, Inc. continues to coordinate with IDOT. Also, MWRDGC has provided IDOT with modeling information. The relevance of the public flood control project is as follows:

- 17 Illinois Administrative Code Chapter 1, Section 3708 "Floodway Construction in Northeastern Illinois" states that a public flood control project is "a flood control project which will be operated and maintained by a public agency to reduce flood damages to existing buildings and structures, which includes a hydrologic and hydraulic study of the existing and proposed conditions of the watershed. Nothing in this definition or this Part shall preclude the design, engineering, construction, or financing, in whole or in part, of a flood control project under this Part by persons or parties who are not public agencies."

- The Code further states that if a downstream restrictive bridge or culvert is scheduled to be removed, reconstructed, modified, or if a public flood control project is scheduled to be built within the next five years, the proposed construction must be

analyzed and shown to meet the requirements of the administrative code for both existing conditions and expected flood profile conditions post-construction.

- The Code states the 100-year frequency flood profile and regulatory floodway may be changed if a public flood control project has been constructed and is operable.

The structures crossing floodplain areas are sized to allow a minimum of 3 feet of freeboard between the roadway edge of pavement and the 50-year headwater elevation, or a design exception would be obtained. Bridges are sized to have a minimum of 2 feet of clearance between the low beam elevation and the 50-year natural water surface elevation, and the low beam would be above the all-time high water level, or a design exception would be obtained.

The IDOT *BDE Manual* Section 26-7.05(C) was used to evaluate and document floodplain impacts. The Addison Creek crossing is both a transverse and a longitudinal encroachment of the floodplain, while the Des Plaines River crossing is a transverse encroachment.

- The longitudinal encroachment of Addison Creek cannot practicably be avoided because the creek parallels I-290 for approximately 1,000 feet, and because of dense existing urban development and the existing freight rail bridge immediately west of 25th Avenue, the I-290 limits of construction cannot shift exclusively to the south of the existing I-290 in this area. Within the normal to 10-year floodplain, there would be a 17.07 acre-feet cut in floodplain fill; from the 10 to 100-year floodplain, there is a projected 4.36 acre-feet floodplain fill.
- The transverse encroachments of Addison Creek and the Des Plaines River would not result in a significant interruption of emergency vehicle or evacuation access because it is anticipated that portions of I-290 and detour routes would be available during construction. The proposed improvements would improve I-290 traffic flow, which in turn may improve emergency response and/or community evacuation times. The transverse encroachment would likely have no significant effect on natural and beneficial floodplain values because the improvement is not anticipated to significantly impact fish or other aquatic species, or change how this floodplain is used for recreation, visual quality, or groundwater recharge. The transverse encroachment of Addison Creek is not anticipated to increase the risk of flooding, nor would it result in incompatible floodplain development. The proposed project, in combination with MWRDGC reservoir and channel projects, is anticipated to reduce flooding in the Addison Creek area.

In accordance with 23 CFR 650.111(e), it has been determined through the floodplain encroachment evaluation that there are no significant floodplain encroachments from the proposed build alternative, and there is no practicable alternative to the longitudinal floodplain encroachment at Addison Creek.

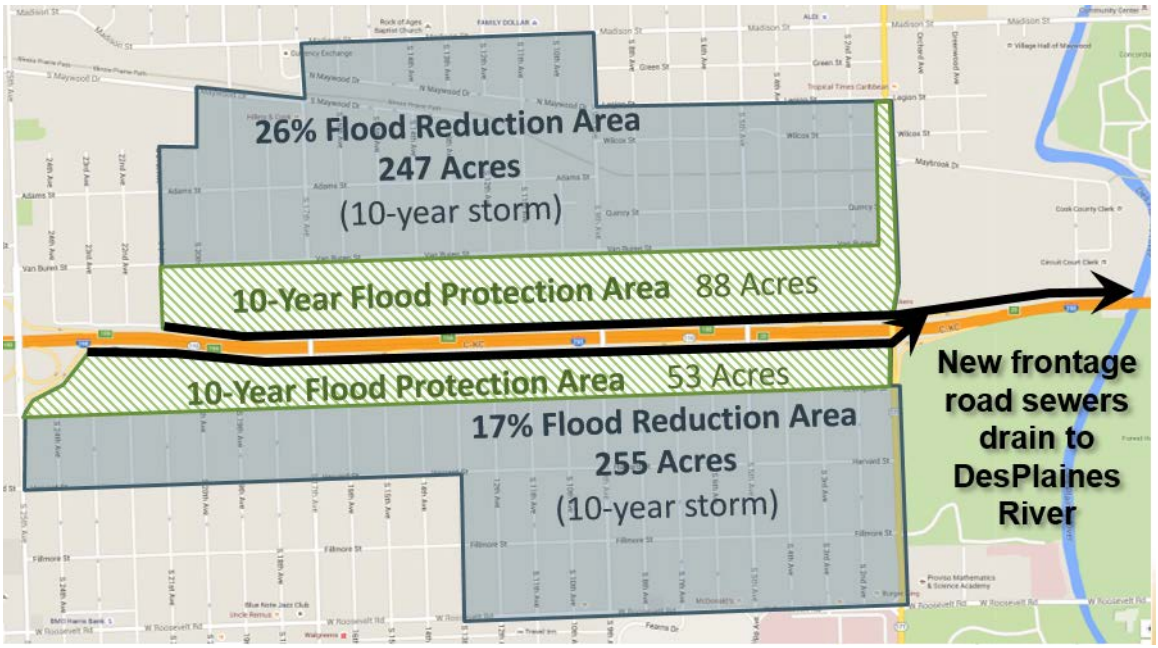
3.9.2.2 Floodway Encroachments

Regulatory floodway encroachments are anticipated at both stream crossings. Proposed structures would comply with the 17 Illinois Administrative Code Part 3708 Rules for Bridge and Culvert Reconstruction or Modification, determining the feasibility of reducing the created head to 0.1 foot over the natural elevation for floods up to and including the 100-year event if the existing structure is a source of flood damage. If the structure is not a source of flood damage, the proposed structures would not increase the flood profile by more than 0.1 foot above existing conditions up to and including the 100-year storm event. On Addison Creek, there is significant overbank flooding resulting in flood damage both upstream and downstream of I-290; however, the existing I-290 bridge over Addison Creek is not the source of flood damage. On the Des Plaines River, there is minor overbank flooding. The existing I-290 bridge over the Des Plaines River is not a source of flood damage. Both existing bridges create a head of 0.1 foot or less over the natural elevation for floods up to and including the 100-year event. The proposed structures would not increase the created head more than 0.1 foot over the natural condition. An IDNR-OWR permit for Floodway Construction in Northeastern Illinois would be issued by IDOT prior to any work within the floodway.

Table 3-47 summarizes the floodway impacts with the proposed build alternative.

Table 3-47. Proposed 100-Year Floodway Impact Summary

Waterway	Location and Description	Normal to 10 Years		10 to 100 Years	
		Cut Volume (acre-feet)	Required Storage (acre-feet)	Cut Volume (acre-feet)	Required Storage (acre-feet)
Addison Creek	At I-290. Two 3-span bridges with piers to be widened or replaced.	0.15	0.00	0.23	0.00
Des Plaines River	At I-290. Two 3-span composite bridges with center pier to be replaced with two new piers.	-0.34	0.34	-0.03	0.03



3.9.2.3 Local Community Coordination

Coordination with local communities occurred to gain more knowledge of specific drainage issues occurring within the local communities. Maywood, Bellwood, and Broadview specifically experience localized chronic stormwater flooding. The existing drainage plan (EDP) was provided to all of the communities along the corridor.

Individual meetings were held with three communities to identify and address chronic local flooding issues. MWRD requested constructing frontage road drainage systems from 25th to 1st Avenues on both sides of I-290, which would help alleviate stormwater flooding in the villages. MWRD requested the new frontage road storm sewer to outlet

into the Des Plaines River. MWRD was not in favor of reusing existing combined sewers, even with storm water detention in oversized pipes. Figure 3-58 identifies the location of the proposed frontage road sewers, which would ultimately drain to the Des Plaines River. The proposed frontage road sewers would allow opportunities for future connections to local separated storm sewers and could increase the level of flood protection to residential properties that occurs independently of the Project Corridor.

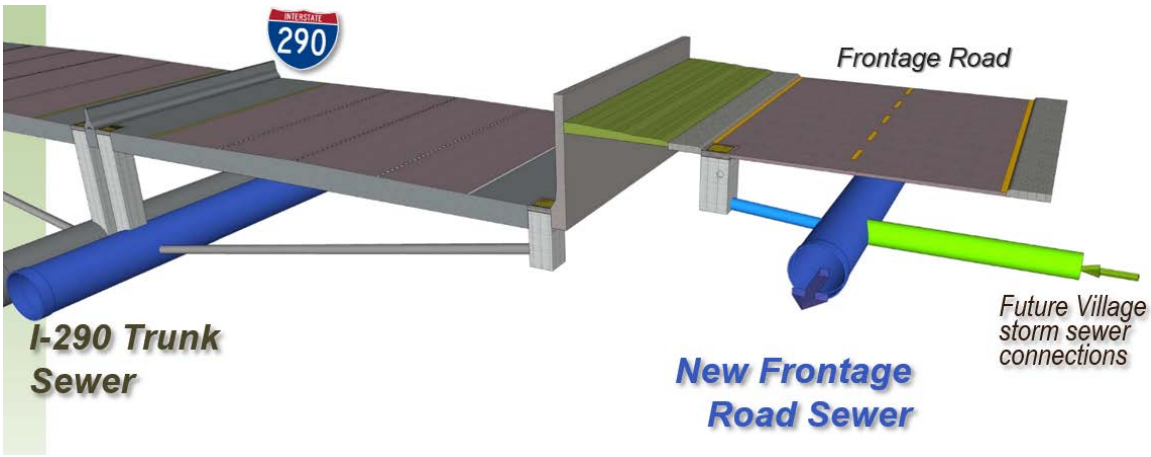


Figure 3-58. Proposed Frontage Road Storm Sewer Location

Note: The proposed outlet pipe from 1st Avenue to the Des Plaines River would be designed to hold the 10-year flood frequency, as shown in the areas directly to the west of 1st Avenue.

Specifically, in the Village of Maywood, coordination identified an opportunity to address local stormwater flooding issues by constructing a new storm sewer trunk line along the I-290 north and south frontage roads of Harrison Street and Bataan Drive. A model of a portion of the proposed frontage road and local drainage is shown in Figure 3-59. The sewers would also intercept overland flow from reaching the expressway as it has in the past during larger storm events. The storm sewer trunk lines would provide an improved outlet for storm sewers in conjunction with the future Village combined sewer separation project. The trunk line would outlet to the Des Plaines River in a single outlet location north of the I-290 bridge. The new storm sewer trunk line would reduce the occurrence of combined sewer overflows (CSO) to the Des Plaines River.

Figure 3-59. Proposed Frontage Road and Local Drainage Detail

3.9.3 Measures to Minimize Harm and Mitigation

Floodplain and floodway impacts will be avoided or mitigated to the extent feasible; however, some floodplain impacts are unavoidable based on roadway design constraints. Hydraulic design studies were completed to properly size proposed drainage structures, provide acceptable freeboard and clearance for proposed roadway improvements, and limit floodway and floodplain impacts in accordance with state rules. Retaining walls are proposed in key locations near the floodplains to minimize impacts. Where fill within the floodplain is unavoidable, local ordinances for potential compensatory storage will be considered, when feasible and cost effective.

Compensatory storage volume mitigation is typically an excavated, hydrologically and hydraulically equivalent volume of storage created to offset the loss of existing flood storage. Per the Part 3708 Rules as applied by IDOT, compensatory regulatory floodway storage must be placed between the normal water elevation and the natural 100-year flood elevation. Compensatory storage must be similar to the impacted storage. All regulatory storage lost between normal to the natural 10-year flood elevation must be replaced below the 10-year flood elevation. All regulatory floodway storage lost between the natural 10-year and the natural 100-year flood elevation must be replaced above the 10-year flood elevation. There is no proposed fill in the Addison Creek and Des Plaines River floodways, so there is no requirement to provide mitigation for lost storage.

3.10 Wetlands

There have been no substantive changes to this section since publication of the DEIS.

This section describes wetlands within the Project Corridor. Section 404 of the CWA defines wetlands as, "Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions."

3.10.1 Affected Environment

A wetland and WOUS delineation was conducted using the methodology presented in the "*Regional Supplement to the COE Wetland Delineation Manual: Midwest Region"* (US Army Corps of Engineers, 2010). After identifying wetland locations from the published National Wetland Inventory, a field reconnaissance was conducted to confirm whether wetlands are located within the Project Corridor. Wetland delineations were conducted in October 2014 within the entire Project Corridor. Based on the results of the field delineations, no wetlands were identified in the Project Corridor.

The Project Corridor is located within the Chicago River and the Des Plaines River watersheds. Generally, wetlands are associated with streams or localized depressional areas. Ponds and rivers within the Project Corridor are discussed in detail in Section 3.7, Water Resources. Within the Project Corridor, the relief is level/flat. The entire Study Area is urbanized and has been affected by development.

Two waterways were identified within the right-of-way of the build alternatives. These two features, the Des Plaines River and Addison Creek, flow perpendicular to the Project Corridor.

3.10.2 Environmental Consequences

Because there are no wetlands located within the No Build Alternative and the build alternatives, there would be no direct or indirect impacts to wetlands. Because there would be no wetland impacts, no measures to minimize harm or mitigation are proposed. Impacts to WOUS are discussed in Section 3.7, Water Resources.

3.11 Special Waste

There have been no substantive changes to this section since publication of the DEIS.

This section discusses areas where current or past property uses may have resulted in contamination and the potential for the proposed project to be affected by, or cause impacts related to, special or hazardous waste. This section also outlines potential mitigation measures, including additional investigations that may be required to avoid or minimize involvement with known special or hazardous wastes.

Contaminated soils or groundwater could potentially be encountered during demolition, construction, or earthwork, resulting in the release of contamination into the air, soil, or water. Special waste sites affect construction projects because of high clean-up costs and safety hazards through exposure and material handling. Exposure to environmental contamination can adversely impact construction workers and public safety and lead to diminished quality of natural resources. Encountering such contamination without prior knowledge can also result in increased project costs and project delays to properly manage the resulting wastes. Therefore, identification, assessment, and investigation of contamination concerns in the corridor are an integral part of the project planning process. Sites with known or potential special or hazardous waste contamination were determined through review and interpretation of information contained within the regulatory agency databases, historical property use data, and visual inspections.

Results of the assessment process were provided in two Preliminary Environmental Site Assessments (PESAs) conducted by ISGS on behalf of IDOT (available upon request). ISGS PESA #1260V, dated July 11, 2012, evaluated the western and central portion of the corridor from east of I-294 to west of Kostner Avenue. ISGS PESA #1260B, dated July 25, 2014, evaluated the eastern portion of the corridor from west of Kostner Avenue to Halsted Street.

Based on the results of the analysis, recognized environmental conditions (RECs) may pose risks of varying degrees to the proposed project. Contamination can jeopardize the health and safety of workers and the public, and can create delays, expense, and liability, especially if contamination is exacerbated by construction. Special waste must therefore be properly investigated, managed, handled, and disposed, as discussed in Section 3.11.3.

PESA project sites identified within the PESA reports are sites that are within or are immediately adjacent to the project limits. REC sites include those PESA project sites that are identified on one or more regulatory databases or are otherwise determined to be sites of potential concern based on historical property use data or visual inspections.

3.11.1 Affected Environment

3.11.1.1 Definitions

According to federal and State of Illinois statutes, the term "hazardous waste" means a solid waste, or combination of solid waste that, because of its quantity, concentration, or physical, chemical, or infectious characteristics may:

- Cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible illness; or
- Pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed.

The term "special waste" in Illinois refers to a broad category of wastes that may result in environmental problems when managed and disposed with municipal-type wastes. Illinois special wastes include any Resource Conservation and Recovery Act (RCRA) hazardous waste, as well as any industrial process waste or pollution control waste that has not been declassified pursuant to Section 808.245 of the Illinois Administrative Code. Non-RCRA Special Wastes are those wastes determined pursuant to Section 808.245 of the Illinois Administrative Code to pose a low or moderate degree of hazard to the environment or the public health in the course of their transport, storage, treatment, or disposal.

Consistent with ASTM Standard Practice E1527-13, the term REC means the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to any release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment. Examples of RECs identified in the PESA include current or former USTs with a documented release, spills, evidence of chemical use or former chemical use, impacted or potentially impacted soil or groundwater, fill soil, drums, and other similar conditions.

De minimis conditions are not recognized environmental conditions. A *de minimis* condition is a condition that generally does not present a threat to human health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate governmental agencies. Examples of *de minimis* conditions include asbestos-containing materials (ACM) in building construction; normal use of lead-based paint (LBP) on buildings and structures; electrical transformers in normal use unless determined to be leaking or otherwise determined to pose a hazard; and agricultural use of pesticides and herbicides.

3.11.1.2 Assessment Methodology

ISGS conducted the PESAs in accordance with *"A Manual for Conducting Preliminary Environmental Site Assessments for Illinois Department of Transportation Infrastructure Projects"* (Erdmann, *et al.*, 2012, 2014) (IDOT-ISGS PESA Manual). The assessments were prepared using historical and geological information including aerial photographs; USGS topographic maps; plat maps; file information of the ISGS regulatory file

information from federal, state, and other agencies; and various other sources of information. A site reconnaissance was completed. The specific methods used to conduct the assessments are contained in the IDOT-ISGS PESA Manual.

PESA project sites are "sites" that are within or immediately adjacent to the project limits. PESA project sites are primarily defined by onsite inspection and may or may not coincide with actual parcel boundaries as defined by Property Identification Numbers (PINs). Sites may be combined with other adjoining sites if land use is similar and if no RECs exist for any site within the group (e.g., all houses in a residential development along the project may be combined into a single site in the PESA report).

The Executive Summary section of the PESA reports summarizes, in tabular form, PESA project sites that have RECs (Table 1); PESA project sites that have *de minimis* conditions only (Table 2); PESA project sites that have neither RECs nor *de minimis* conditions (Table 3); and PESA project sites that are adjoining the proposed project that also appear on regulatory lists (Table 4).

3.11.1.3 Existing Conditions

Land use within the Project Corridor is a mix of commercial, industrial, and residential uses. The nature of potential contaminant sources within the Project Corridor is as varied as the types of existing land uses. Spills or accidental releases can potentially occur through handling operations and leaks from storage tanks and containers. Commercial and industrial operations have the potential to release a broad range of hazardous substances such as petroleum and cleaning solvents into the soil and groundwater. Potential releases of hazardous substances from facilities that treat, store, transfer, or dispose of municipal, industrial, or construction wastes can also occur. Materials contained within the structures located throughout the Project Corridor have the potential to contain ACM, and painted surfaces/components may contain LBP.

3.11.1.4 Environmental Regulatory Agency Databases

Facilities with known or potential special/hazardous wastes are listed in numerous databases including those maintained by USEPA, IEPA, the Illinois Emergency Management Agency (IEMA), and the Office of the Illinois State Fire Marshall (OSFM).

The regulatory database searches were conducted by ISGS in accordance with the PESA guidance manual to identify known or potential contamination from regulated substances within the Project Corridor. A description of the individual databases included in this analysis and the associated findings are summarized below.

<u>*Federal*</u>

- **Resource Conservation and Recovery Information System (RCRIS) Database** – RCRIS is a national computerized management information system that contains information related to compliance with, or violation of, the federal RCRA. RCRA requires that generators, transporters, treaters, storers, and disposers of hazardous waste provide information concerning their activities to state environmental agencies. This database is used primarily to track handler permits or closure status,

compliance with federal and state regulations, and cleanup activities. The database is maintained by the USEPA. There were 101 PESA project sites identified in the RCRA hazardous waste generator database.

- **Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS) Database** – CERCLIS is a national information system that contains information related to the Comprehensive Environmental Response Compensation and Liability Act (CERCLA or Superfund). Under CERCLA, USEPA is charged with maintaining a National Priorities List (NPL), which identifies the nation's worst hazardous waste sites, and for informing the public about sites that warrant further investigation and pose the most significant risk to public health, welfare, and the environment. CERCLIS contains sites that are on the NPL, as well as sites that are in the screening and assessment phase for possible inclusion on the NPL (referred to as "NPL-eligible"). As of February 1995, CERCLIS sites designated "No Further Remedial Action Planned (NFRAP)" have been removed from CERCLIS. The NFRAP sites may be those where, following an initial investigation, no contamination was found, contamination was removed quickly without the need for the site to be placed on the NPL, or the contamination was not serious enough to require Federal Superfund action or NPL consideration. A NFRAP archive status indicates that to the best of the USEPA's knowledge, Superfund has completed its assessment of a site and has determined that no further steps will be taken to list that site on the NPL. The CERCLIS database is maintained by the USEPA. Since the time the PESAs were completed, the CERCLIS Public Access Database, which contained a selected set of publicly releasable Superfund program data, has been retired. The USEPA is transitioning to the Superfund Enterprise Management System, or SEMS, which includes the same data and content as CERCLIS. There were four PESA project sites identified in the CERCLIS database.
- **Toxic Release Inventory (TRI) Database** – Under the Emergency Planning and Community Right-to-Know Act of 1986 (EPCRA), the USEPA developed a database containing data on disposal or other releases of over 650 toxic chemicals from thousands of US facilities and information about how facilities manage those chemicals through recycling, energy recovery, and treatment. The TRI provides information to the public on the release of toxic chemicals from manufacturing facilities in any given area. Industrial facilities provide information that includes: the location of the facility where the chemicals are manufactured, processed, or otherwise used; amounts of chemicals stored on-site; estimated quantities of chemicals released; on-site source reduction and recycling practices; and estimated amounts of chemicals transferred to treatment, recycling, or waste facilities. The TRI data for chemical releases to land are limited to releases within the boundary of a facility. Releases to land include: landfills; land treatment/application farming; and surface impoundments, such as topographic depressions, man-made excavations, or diked areas. The database is maintained by the USEPA. One PESA project site was identified in the TRI database.
- **USEPA Brownfield Database** – The term "brownfield site" means real property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant. Brownfield

sites are generally industrial or commercial properties that are abandoned, inactive, or underutilized due to environmental contamination. The USEPA provides technical assistance and some funding for assessment and cleanup of designated sites. They can also provide tax incentives for cleanup that is not paid for outright; specifically, cleanup costs are fully tax deductible in the year they are incurred. The database is maintained by the USEPA. No PESA project sites were identified in the USEPA Brownfield database.

- **ERNS Database** – The Emergency Response Notification System (ERNS) records and stores information on reported releases of oil and hazardous substances. The ERNS database is maintained by the USEPA. There were 13 PESA project sites identified in the ERNS database.
- **Transformer Databases** – The USEPA maintains two databases on transformer registration and quarterly activities regarding polychlorinated biphenyl (PCB)-containing transformers. There were two PESA project sites identified in the PCB databases.

Illinois

- **Illinois Voluntary Site Remediation Program (SRP) Database** – The SRP is an Illinois program for property owners to voluntarily clean up contaminated property. The intent of the program is to provide persons seeking to perform or performing investigative or remedial activities the opportunity to receive review and evaluation services, technical assistance, and No Further Remediation (NFR) determinations from the IEPA. Letters of NFR determinations are issued for sites that have successfully demonstrated, through proper investigation, and, where warranted, remedial action, that environmental conditions do not present a significant risk to human health or the environment. The database is managed by IEPA. There were 45 PESA project sites identified in the SRP database.
- **Illinois Clean Construction and Demolition Debris (CCDD) Sites Database** – A CCDD facility is a current or former quarry, mine, or other excavation site accepting CCDD as fill material. CCDD means uncontaminated broken concrete without protruding metal bars, bricks, rock, stone, reclaimed or other asphalt pavement, or soil generated from construction/demolition activities. Potential environmental concerns exist with these sites because current operating facilities have operated without a regulatory definition of "uncontaminated." The database is maintained by IEPA. No PESA project sites were identified in the CCDD database.
- **Illinois Brownfield Database** – This database is similar to the brownfield database maintained by USEPA; however, assistance is provided at the state level. The database is maintained by IEPA. One PESA project site was identified in the IEPA Brownfield database.
- **Illinois Active Landfills Database** – Active permitted landfill facilities in the State of Illinois are listed in this database. The database is maintained by IEPA. No PESA project sites were identified in the Illinois Active Landfills database.

- **Coal Gasification Sites Database (Former Manufactured Gas Plant [FMGP])** – Historically, gas for lighting and heating was produced from coal by numerous power companies and municipalities. Byproducts of gas manufacturing included coal tar (containing polycyclic aromatic hydrocarbons, or PAHs) and benzene. Commonly, these and other wastes associated with gas manufacturing were left onsite, aboveground and underground, which may pose a significant threat to public health and the environment. One PESA project site was identified in the Coal Gasification Sites database.
- **Illinois Abandoned and Inactive Landfills Database** – IEPA maintains a list of Abandoned and Inactive Landfills in the State of Illinois. No PESA project sites were identified in the Illinois Abandoned and Inactive Landfills database.
- **Illinois UST Sites** – A database of regulated USTs in Illinois that contain regulated substances, including petroleum products or hazardous substances, is maintained by OSFM. There were 115 PESA project sites identified in the UST database.
- **Illinois Leaking Underground Storage Tank (LUST) Sites** – Regulated USTs in Illinois that have a suspected or confirmed leak are listed in this database. LUSTs contain regulated substances, including petroleum products or hazardous substances, such as those typically found at gasoline stations, fleet fueling facilities, and industrial sites. The database is maintained by IEPA. There were 72 PESA project sites identified in the LUST database.
- **Illinois Bureau of Land (BOL) Open Dump Sites** – Abandoned piles of household garbage, bags of yard waste, appliances, old barrels, used tires, and demolition debris such as lumber, shingles, pipes, and asbestos can threaten the health of humans, wildlife, and the environment. Known as open dumps, these sites can be found throughout Illinois – heaped at the bottom of ravines, in empty lots and pastures, and along roadsides. An open dump is an illegal waste disposal site and should not be confused with a permitted municipal solid waste landfill or a recycling facility. If allowed to remain, open dumps often grow larger, and may attract dumping of solid and hazardous wastes. Open dumps pose the following health, safety, and environmental threats: fire and explosion; inhalation of toxic gases; injury to children playing on or around the dump site; disease carried by pests; contamination of waterways and lakes; contamination of soil and groundwater; contamination of drinking water; damage to plant and wildlife habitats; and decrease in the quality of life to nearby residents and the local community. This database in maintained by the IEPA BOL. There were 210 PESA project sites identified in the BOL database.
- **Illinois Spills Database** – The primary responsibility of IEMA is to better prepare the State of Illinois for natural, manmade, or technological disasters, hazards, or acts of terrorism. IEMA coordinates the State's disaster mitigation, preparedness, response, and recovery programs and activities, functions as the State Emergency Response Commission, and maintains a 24-hour Communication Center and State Emergency Operations Center (SEOC). As part of their responsibility, IEMA maintains a database of reported incidents involving the release of oil, hazardous

materials, or other contaminants to the land, air, or waters of the state. There were 93 PESA project sites identified in the IEMA database.

- **Activity and Use Limitations (AUL) Database** – An AUL is a control with the intent to restrict or limit the use of, or access to, a site or facility. These restrictions, which may include institutional and/or engineering controls, are intended to prevent adverse impacts to individuals or populations that may be exposed to hazardous substances and petroleum products in the soil or groundwater on the property. There were 52 PESA project sites identified in the AUL database.
- **Highway Authority Agreement (HAA) Database** – A Highway Authority Agreement (HAA) is an institutional control agreement with a highway authority where the requirements of 35 Illinois Administrative Code (35 Ill. Adm. Code) 742.1020(b) and (c) are met and IEPA has determined that NFR is required. There were 10 PESA project sites identified in the HAA database.

A total of 242 PESA project sites were found in one or more regulatory databases. A summary of PESA project sites found in the above environmental regulatory databases is provided in Table 3-48. PESA project sites listed within at least one environmental regulatory database are considered REC sites.

3.11.1.5 Non-Regulatory Agency Listed Sites/Concerns

PESA project sites with potential special/hazardous waste concerns not included on regulatory agency databases were identified in the PESA reports prepared by ISGS based on visual inspections or historical data information. In accordance with the PESA guidance protocol, these inspections were conducted for parcels within the build alternatives, as well as those parcels along (i.e., intersecting, touching or bounding at any point) the proposed project. Observations were made for indications of contamination such as stained or discolored soil and/or pavement; stressed vegetation; debris or other uncontrolled dumping or waste disposal; drums and chemical containers; location of PCB-containing transformers; groundwater monitoring wells; and evidence of underground and aboveground storage tanks. Standard historical research includes plat maps, Sanborn fire insurance maps, city directories, historical topographic maps, aerial photographs and imagery, and Illinois manufacturers' directories. Based on the completed visual inspections and historical data evaluations, 253 additional REC sites and/or additional concerns beyond the sites with database listings were identified in the PESA reports, which could potentially impact the proposed project due to the presence of special or hazardous wastes.

Table 3-48. Summary of PESA Project Sites in Environmental Regulatory Databases

Database	Total
Federal Database Sites

3.11.2 Environmental Consequences

The proposed project itself does not involve the use or handling of contaminating substances; however, construction activities (i.e., excavation or dewatering) have the potential of encountering hazardous or special waste (i.e., contaminated soil and/or groundwater). Potentially hazardous situations can be mitigated efficiently provided that stakeholders have prior knowledge and are prepared for the situation. Unexpected conditions can create delays, expense, and liability, especially if contamination or other conditions are exacerbated by construction, and can jeopardize the health and safety of workers and the public. Planned excavation may encounter contamination and require disposal permits, special material handling techniques, remediation, monitoring, or avoidance.

The ISGS PESA reports identified numerous REC sites, any of which have the potential for soil or groundwater contamination, and could potentially pose a risk to construction activities. These REC sites may require further evaluation, including testing (preliminary site investigation [PSI]). The determination whether further assessment is necessary will be evaluated as the proposed project progresses and detailed design becomes available. The decision depends on the nature of the REC, its proximity to the planned construction activities, and its potential impact to the proposed project. Mitigation is discussed in Section 3.11.3.

Based on information from both PESAs, and considering overlapping duplicates between the two reports, 495 unique sites (242 REC sites listed within at least one environmental regulatory data base plus 253 additional REC sites identified in the PESA reports) were determined to be RECs posing a potential concern to the proposed project. These REC sites are listed in Table 1 of the Executive Summary section of the PESA reports.

3.11.3 Measures to Minimize Harm and Mitigation

Accidental spills of hazardous materials and wastes during construction or operation of the transportation system require special response measures. Occurrences will be handled in accordance with local government response procedures.

Further environmental studies may be necessary if the proposed project requires work to be performed on or adjacent to a property identified with a REC. It is the responsibility of IDOT to determine if any of the sites with RECs, or right-of-way adjacent to the RECs, will be impacted with the proposed work. A PSI is required if a REC site identified in Table 1 of the PESA Executive Summary involves any of the following situations:

- New right-of-way or easement acquisition (temporary or permanent);
- Railroad right-of-way, other than single rail rural with no maintenance facilities;
- Building demolition/modification; or
- Excavation activities occurring on existing right-of-way adjoining a REC site.

In some cases, the affected portion of the property that involves the REC can be risk managed through avoidance and not require additional assessment. If the affected property containing the REC is fully taken, then the property is ineligible to be risk managed. If risk managing is not possible, a PSI is required to determine the nature and extent of potential contamination.

Right-of-way or easement acquisition is planned for several locations along the Project Corridor, as described previously in Section 3.1.7. Based on the results of the PESA evaluation, 13 PESA project sites appear to be either part of, or immediately adjacent to, the areas of planned acquisition. For those identified situations, the IDOT District Bureau of Land Acquisition shall coordinate the acquisition with IDOT Bureau of Design and Environment, Central Bureau of Land Acquisition, and the Chief Counsel's

Office to determine if an "All Appropriate Inquiries" (AAI) assessment (parcel-specific Phase I Environmental Site Assessment) is required prior to the acquisition process for additional liability protection under CERCLA.

Once the nature and extent of construction activities are fully known and the areas of contamination are delineated through PSI testing, quantities of impacted soil and water will be estimated. Contaminated material will be managed and disposed of in accordance with applicable federal and state laws and regulations and in a manner that would protect human health and the environment. Special waste issues that may arise in the construction phase will be managed in accordance with the *"IDOT Standard Specifications for Road and Bridge Construction and Supplemental Specifications and Recurring Special Provisions."* The specification and special provision addresses the transportation and proper disposal of contaminated soil and water, including requirements for sampling, monitoring, management, disposal, and reporting.

3.12 Special Lands

Since publication of the DEIS, the following substantive changes to this section have been made:

- Updated Section 3.12.1.4 regarding the use of Urban Park and Recreation Recovery (UPARR) monies at Columbus Park;
- Updated Section 3.12.2 to clarify that no Land and Water Conservation Fund (LWCF) or UPARR-funded park sites would be impacted;
- Added a new Section 3.12.3 to document a *de minimis* impact finding for three parks in the Village of Forest Park; and
- Added a new Section 3.12.4 to document a Section 4(f) exception finding for certain project improvements proposed at Columbus Park.

This section discusses special lands, including parks, recreational areas, and nature preserves, found within the Project Corridor**.** In the Project Corridor, there are 51 parks and recreation areas and a portion of the Illinois Prairie Path**.** Potential effects to these resources from the build alternatives are presented, along with a discussion of certain improvements to Columbus Park in consultation with the Chicago Park District.

3.12.1 Affected Environment

The location of parks, recreation facilities, and forest preserves within or near the Project Corridor are illustrated in Figure 3-60. Each facility within the footprint of the Project Corridor is described in the following sections in terms of its general purpose, whether it is public or private, and whether its development involves the use of lands purchased or improved with Section 6(f) LWCF, UPARR and/or Open Space Land Acquisition and Development (OSLAD) funding from Illinois.

3.12.1.1 Federal and State Lands

There are no federal or state-operated parks, recreation areas, or natural areas in the Project Corridor.

3.12.1.2 Existing Parks and Recreational Areas

Within the 1-mile-wide Project Corridor, there are 51 parks and recreation areas (Table 3-49). These range in size from small 0.1-acre tot lots to the 150-acre James Garfield Park located at 100 North Central Park Drive in the City of Chicago. All of the parks, with the exception of the Thomas Jefferson Woods and Millers Meadow Forest Preserve in Forest Park and Garfield Park and Union Park in Chicago, are located completely within the Project Corridor. Only 0.03 acre of Thomas Jefferson Woods (118.3 total acres), 1.57 acres of Millers Meadow (334.4 total acres), and 54.5 acres of Garfield Park (184.7 total acres) are located outside of the Project Corridor. Several of the parks are immediately adjacent to the I-290 right-of-way: Park District of Forest Park, Veterans Park and the Dog Park in Forest Park; Rehm Park, Barrie Park, and Wenonah Park in Oak Park; and Columbus Park, Park No. 422, and Horan Park in the City of Chicago.

In addition to the numerous parks in the Project Corridor, a portion of the Illinois Prairie Path is located along the northern edge of the corridor through Hillside, Bellwood, and Maywood. The Illinois Prairie Path is a multi-use nature trail for non-motorized public use. The trail spans approximately 61 miles through Cook, DuPage, and Kane counties in northeastern Illinois along the former right-of-way of the old Chicago Aurora & Elgin electric railroad. Initiated in 1963, the Illinois Prairie Path is the first US rail-to-trail conversion in the nation. The eastern end of the trail starts at 1st Avenue and Maybrook Drive in the Village of Maywood, but it also includes a discontinuous trail link to the east that was constructed in 2006, crossing the Des Plaines River between Maybrook Drive in Maywood and a parking area at the CTA Station in Forest Park. Maybrook Drive serves as a connection between the two trails. Currently, there are no funded projects to expand the path or create connections to the path. The Village of Maywood Comprehensive Plan (2008) calls for improved connections to the Prairie Path:

> *The Prairie Path should be extended east from its current terminus at First Avenue to the Des Plaines River and possibly to the Forest Park CTA Blue Line Station. The Path should be enhanced with lighting, benches, and special landscaping along its entire length through Maywood.*

3.12.1.3 Nature Preserves

There are no nature preserves within the Project Corridor.

3.12.1.4 LWCF, OSLAD and UPARR-Funded Sites

Section 6(f) of the Land and Water Conservation Fund Act of 1965 (LWCF) (Public Law 88-578, 16 USC 4601-8(f)(3)) states that properties purchased or improved with LWCF funds cannot, "without the approval of the Secretary [of the US Department of Interior], be converted to other than public outdoor recreation uses." The OSLAD program is an Illinois state-financed grant program that provides funding assistance to local government agencies for acquisition and/or development of land for public parks, open space, or conservation purposes. This program is similar to the LWCF program in

Illinois in that both are managed by IDNR, have concurrent application due dates, equal grant maximums, and similar general rules (IDNR, 2011b). The programs differ in their financing resources.

Properties purchased using LWCF funds (Section 6(f) lands) or properties purchased and/or developed using OSLAD grant program funds are protected and may also be a resource protected by Section 4(f) of the USDOT Act of 1966 (49 U.S.C. 303).

Two parks, the Park District of Forest Park and Garfield Park in the City of Chicago, previously received LWCF monies, while two parks were awarded OSLAD funds, Maple Park in Oak Park and the Park District of Forest Park in Forest Park.

In 2014 the State of Illinois announced $16.5 million in grant awards for 46 local park projects across Illinois. Included in the grant announcement was the Park District of Oak Park for which $400,000 in OSLAD grant funds were identified for improvements to Maple Park, including renovation of existing ball fields, construction of a new playground, and creation of two new athletic fields.

In January 2015 the State of Illinois announced that 75 park and recreation agencies throughout the State of Illinois would receive a total of $26,072,000 in OSLAD grants for FY15. Within the Study Area, the Park District of Forest Park was identified to receive a $400,000 OSLAD grant. The Park District of Forest Park plans to use its portion of the grant funding for landscaping improvements and exterior construction on the property formerly known as the Roos Property. Landscape elements of this plan include walking trails, a pavilion, sensory gardens, open grass space, and bicycle parking.

The UPARR Act of 1978 states "No property improved or developed with UPARR assistance shall, without the approval of NPS, be converted to other than public recreation uses. A conversion will only be approved if it is found to be in accord with the current local park and recreation Recovery Act Program and/or equivalent recreation plan and only upon such condition as deems necessary to assure the provision of adequate recreation properties and opportunities of reasonably equivalent location and usefulness. Section 1010 is designed to ensure that areas or facilities receiving UPARR grant assistance are continually maintained in recreation use and available to the general public."

In the Study Area near the project limits, Columbus Park received UPARR grant monies. These monies were used for improvements approved in 1981 for remodeling of the gymnasium building located west of Central Avenue, approximately 700 feet northeast of the project limits. The improvements were completed in 1984.

3.12.1.5 Planned or Proposed Park and Recreational Facilities

As previously discussed, the Park District of Forest Park is planning expansion of their existing park on the property known as the Roos Property at 7358 West Harrison Street. The property was originally purchased in 2013 and dependent on the receipt of 2015 OSLAD funds, the Park District would further develop the site with walking trails, a pavilion, sensory gardens, open grass space, and bicycle parking.

Per the Park District of Oak Park *2014-2018 Capital Improvement Plan*, improvements and/or renovations are planned for several parks in the Project Corridor including Longfellow, Maple and Rehm (http://www.pdop.org/file.aspx?DocumentId=1691).

The *2015 Update to the 5-Year Capital Improvement Plan* for the Forest Preserve District of Cook County includes plans for the development of a new off-leash dog area, a disc golf course, walking trails and improved picnic groves at Miller Meadow[54].

3.12.2 Environmental Consequences

Under the No Build Alternative, there would be no impacts to any existing parks or recreational resources. In addition, there would be no improvements to park access in the Project Corridor.

No part of the proposed project will encroach on either of the two parks described previously as having received LWCF funds, Maple Park in Oak Park and the Park District of Forest Park in Forest Park (the 16-inch Softball Hall of Fame at 7501 West Harrison Street). Consequently, neither park will be adversely affected. As will be described later in this section, a Section 4(f) exception is determined at Columbus Park to provide for certain public pedestrian enhancements along the park's southern boundary. These proposed enhancements, however, are apart from the gymnasium which previously received UPARR funding and are separated by approximately 700 feet. This facility within Columbus Park will, therefore, not be impacted by the proposed reconstruction of the Eisenhower Expressway; consequently, there will be no conversion of park property for which the UPARR monies were granted. See also Section 4.5.1 for consultation undertaken with the US Department of the Interior in response to comments provided on the DEIS.

There would be no direct or temporary use of park or recreational resources associated with any of the build alternatives with three exceptions which are described below in the Village of Forest Park and at Columbus Park.

Implementation of a build alternative could have beneficial effects to the recreational facilities in the Project Corridor with improved connectivity and access, including the improvement of bicycle and pedestrian access across I-290 at existing bridge crossing locations and the creation of a multi-use trail proposed to connect DesPlaines Avenue with Austin Boulevard along the north side of I-290. Also, the build alternatives include reconstruction of the 1st Avenue/Maybrook Drive intersection to provide a protected crossing of 1st Avenue to help complete the Illinois Prairie Path trail connection to the east. See Section 3.1.1.5, Transportation Network for a discussion of various bicycle and pedestrian improvements throughout the Project Corridor.

[54] http://fpdcc.com/downloads/FPCC-2015-2019-DRAFT-Capital-Improvement-Plan_web.pdf and http://fpdcc.com/site-plans/

3.12.2.1 Village of Forest Park Parklands

The proposed project would require small areas of new right-of-way from two parks in the Village of Forest Park to accommodate certain pedestrian and bicycle access improvements requested by the Village. The proposed improvements would occur as follows:

- Veterans Park (at 631 Circle Avenue): 1,160 square feet (temporary)/790 square feet (permanent) to provide for a wider, 12-foot sidewalk and a new on-street 6-foot bicycle lane along Circle Avenue, and a new sidewalk on the park's western boundary to connect the park with the proposed shared-use path (requested by Village); and
- The Dog Park (at 632 Circle Avenue): 840 square feet (temporary)/575 square feet (permanent) to provide for a wider, 10-foot sidewalk along Circle Avenue and a new on-street 6-foot bicycle lane (requested by Village).
- Park District of Forest Park (Recreation Center-Roos Property) (at 7358 West Harrison Street): 3,955 square feet (temporary) to provide work space for sidewalk installation on the west side of Circle Avenue.

In evaluating the consequences of these proposed improvements, consideration was given to Section 4(f) of the USDOT Act of 1966. This act governs the use of land from publicly owned parks, recreation areas, wildlife or waterfowl refuges, and public or private historic and archaeological sites for federal highway projects.

Section 4(f) Regulations

Section 4(f) of the USDOT Act of 1966 (49 USC Section 303 and 23 USC 138) was enacted to preserve publicly owned land used for recreation, wildlife, and waterfowl refuges. Section 4(f) resources also include public and private historic properties that are listed or eligible for inclusion in the NRHP, as well as archaeological sites that are listed or eligible for inclusion in the NRHP and warrant preservation in place.

Section 4(f) stipulates that FHWA and other USDOT agencies cannot approve the use of land from publicly owned parks, recreation areas, wildlife and waterfowl refuge areas, or public and private historic sites unless the following conditions apply:

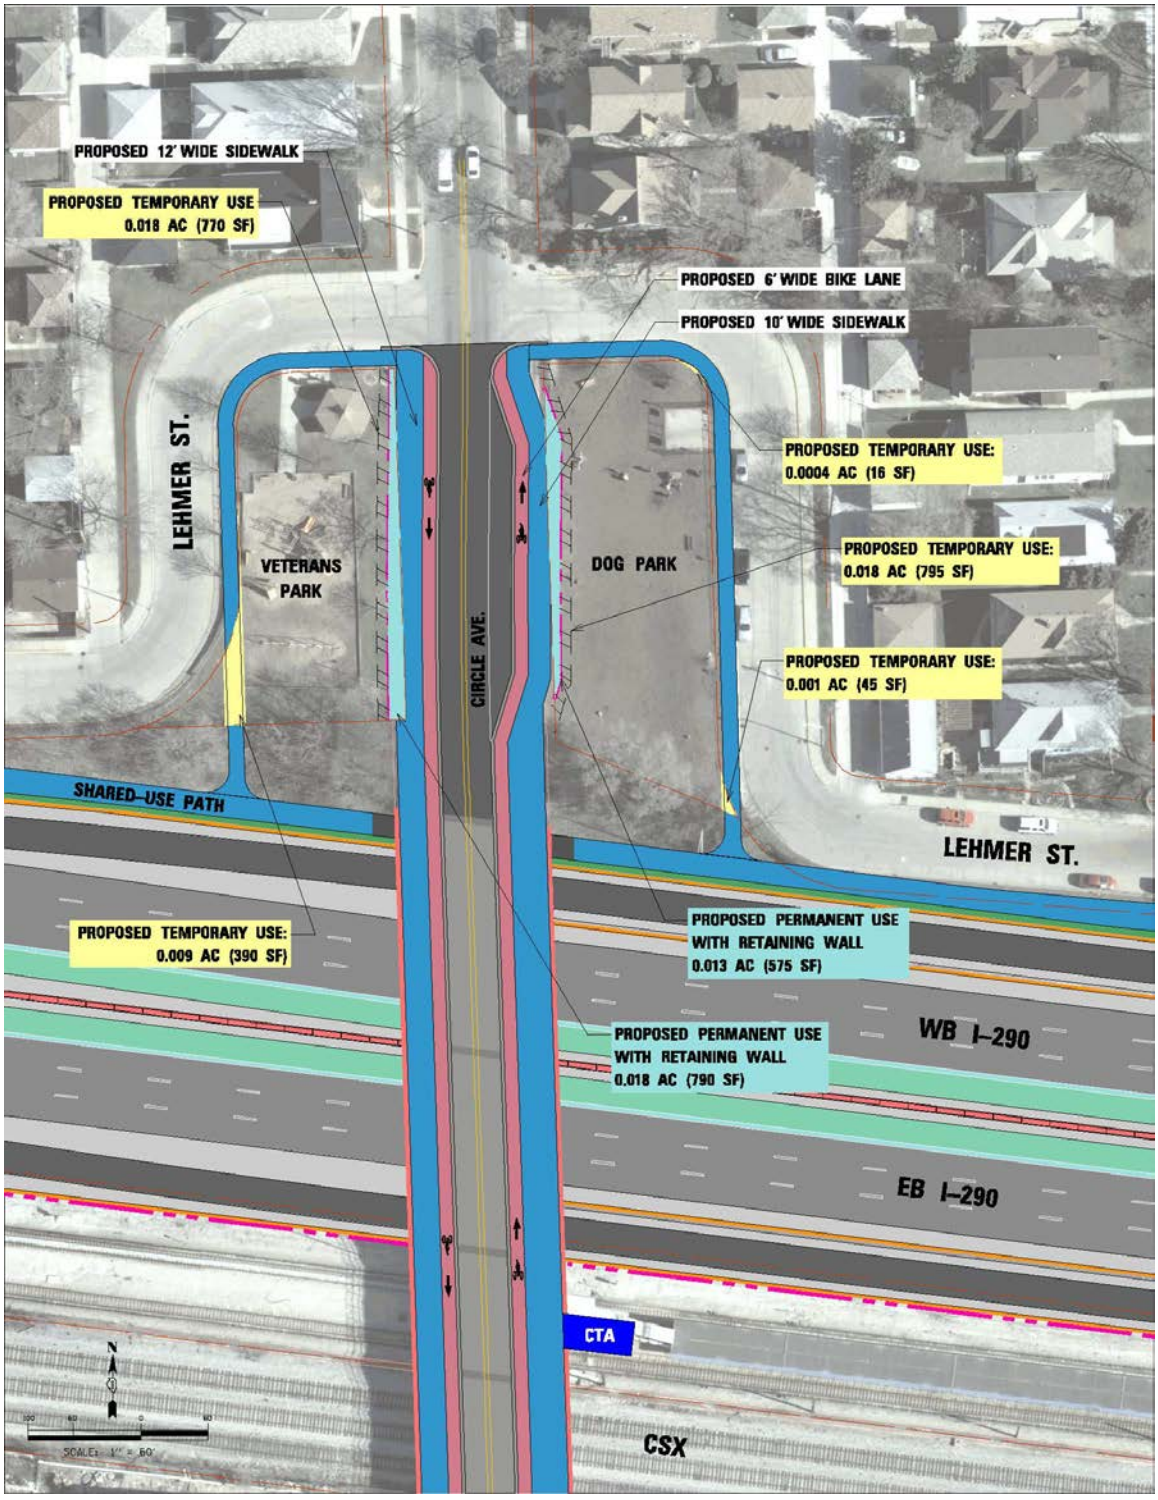
- There is no feasible and prudent alternative to the use of the land; and
- The action includes all possible planning to minimize harm to the property resulting from use; or
- The Secretary of Transportation determines, after public notice and opportunity for public review and comment, that the use of the property, including any measure(s) to minimize harm committed to by the applicant will have a de minimis impact as defined in 23 CFR 771.17. The officials with jurisdiction (OWJ) over the Section 4(f) property must concur in writing that the project will not adversely affect the activities, features, or attributes that make the property eligible for Section 4(f) protection.

Types of "uses" include:

- Permanent incorporation of land into a transportation facility (Direct Use).
- Temporary use of land that is adverse in terms of the statute's preservation purpose, unless an exception is applicable according to 23 CFR 774.13 (2008).
- Constructive use, as determined by the criteria in 23 CFR 774.15, meaning the transportation project does not incorporate land from a Section 4(f) property, but the project's proximity impacts are so severe that the protected features, attributes, or activities that qualify the property for protection under Section 4(f) are substantially impaired (Constructive Use).

The evaluation that follows was undertaken with these potential uses evaluated at Veterans Park, the Dog Park, and the Park District of Forest Park (Recreation Center – Roos Property).

Veterans Park



Planned project improvements at Veterans Park would include construction of a new sidewalk and widening of an existing sidewalk. As shown on Figure 3-61, a small amount of parkland would be needed along the park's western and eastern boundaries: 1) for a new sidewalk along the west boundary, which would provide a connection to the shared-use path proposed to parallel I-290, and 2) to widen the existing sidewalk on the eastern boundary along Circle Avenue from 5 feet to 12 feet. New bicycle lanes, 6 feet in width, are proposed along northbound and southbound Circle Avenue.

Permanent, Constructive, or Temporary Parkland Use. Permanent and temporary use of land within Veterans Park would occur. The permanent use would consist of 790 square feet to widen the existing sidewalk from 5 feet to 12 feet on the western side of Circle Avenue. This permanent use, to be accomplished as a conveyance of ownership to IDOT, would require approximately 0.07 percent of the parkland along its perimeter with no effect to existing facilities. At the same time, approximately 770 square feet would also be temporarily used along Circle Avenue to accommodate a transition in grade from the wider sidewalk to the park, along with 390 square feet for the new sidewalk connecting to the proposed shared-use path along I-290, for a total of 1,160 square feet. For the parkland that would be temporarily used by IDOT, a temporary easement would be conveyed or a permit issued to IDOT. Ownership of the temporary easement area would be retained as part of Veterans Park and park uses would re-commence once construction is complete.

No constructive use at Veterans Park would occur because no impairment of the activities, features, or attributes that qualify the property for protection under Section 4(f) would result from activities associated with the proposed project.

Avoidance and Minimization Options. No avoidance or minimization options are available along the western boundary, unless the connection to the shared-use path was eliminated. Removal of this connection would not meet the purpose and need for this element of the project, nor would it meet the design intent to improve pedestrian safety

Figure 3-61. Veterans Park and the Dog Park –
Proposed Access Improvements at Circle Avenue and I-290

Source: WSP Parsons Brinckerhoff, 2016.

and connectivity. Along Circle Avenue, the existing sidewalk narrow-width would need to be retained and the proposed bicycle lane eliminated to avoid the permanent and temporary use to construct the wider sidewalk. Minimization measures developed at this location within the park include the use of a retaining wall to limit the extent of grade change into the park. Other considerations, such as narrowing the sidewalk width, were also evaluated. Given the intent to reconstruct project facilities to current standards, however, such a design would result in a substandard condition and is not recommended for that reason.

Dog Park

Planned project improvements at the Dog Park would be similar to those for Veterans Park, but the area of impact would be smaller. As shown in Figure 3-61, an incidental amount of parkland would be needed along the park's western and eastern boundaries 1) for a new sidewalk connecting to the shared-use path and 2) to widen the existing sidewalk along Circle Avenue from 5 feet to 10 feet.

Permanent, Constructive, or Temporary Parkland Use. Permanent and temporary use of land within the Dog Park would occur. The permanent use would consist of 575 square feet to widen the existing sidewalk from 5 feet to 10 feet on the east side of Circle Avenue. The permanent use, to be accomplished as a conveyance of ownership to IDOT, would require approximately 0.04 percent of the parkland along its perimeter with no effect to existing activities at the park, although the perimeter fence would need to be relocated along Circle Avenue. Approximately 795 square feet would also be temporarily used along Circle Avenue to accommodate a transition in grade from the wider sidewalk to the park, while 45 square feet would be needed to complete the sidewalk connection to the proposed shared-use path, for a total of 840 square feet. For the parkland that would be temporarily used by IDOT, a temporary easement would be conveyed or a permit issued to IDOT. Ownership of the temporary easement area would be retained as part of the Dog Park and park uses could re-commence once construction is complete..

No constructive use at the Dog Park would occur because no impairment of the activities, features, or attributes that qualify the property for protection under Section 4(f) would result from activities associated with the proposed project.

Avoidance and Minimization Options. There are no avoidance or minimization options available along the eastern boundary, unless the connection to the shared-use path was eliminated. Removal of this connection would not meet the purpose and need for this element of the project, nor would it meet the design intent to improve pedestrian safety and connectivity. Along Circle Avenue, the existing narrow sidewalk width would need to be retained and the proposed bicycle lane eliminated to avoid the permanent and temporary use to widen the existing sidewalk. Measures to minimize impacts at this location include a retaining wall to limit the extent of grade change into the park. Other considerations, including a narrower sidewalk width, were also considered; however, such a design would result in a substandard condition and is not recommended for that reason, given the intent to reconstruct project facilities to current standards.

Park District of Forest Park – Recreation Center (Roos Property)

Permanent, Constructive, or Temporary Parkland Use. Temporary use of land within the Park District of Forest Park, Recreation Center (Roos Property) would occur (Figure 3-62). The land temporarily used would consist of 3,995 square feet, which would allow for construction of a new 5-foot-wide sidewalk along the property's eastern boundary on the west side of Circle Avenue. The parkland temporarily used would be retained as part of the Recreation Center (Roos Property) once construction is complete.

No constructive use at the Recreation Center (Roos Property) would occur because no impairment of the activities, features, or attributes that qualify the property for protection under Section 4(f) would result from activities associated with the proposed project.

Avoidance and Minimization Options. No avoidance or minimization options are available unless the sidewalk was eliminated. Removal of the sidewalk would not meet the purpose and need for this element of the project, nor would it meet the design intent to improve pedestrian safety and connectivity. Given the intent to reconstruct project facilities to current standards, however, such a design would result in a substandard condition and is not recommended for that reason.

A summary of the proposed project's involvement with the public parks in the Village of Forest Park is shown in Table 3-50, with several small areas along the perimeter of Veterans Park and the Dog Park required for permanent and temporary use and a small area of temporary use along the eastern perimeter of the Recreation Center – Roos Property.

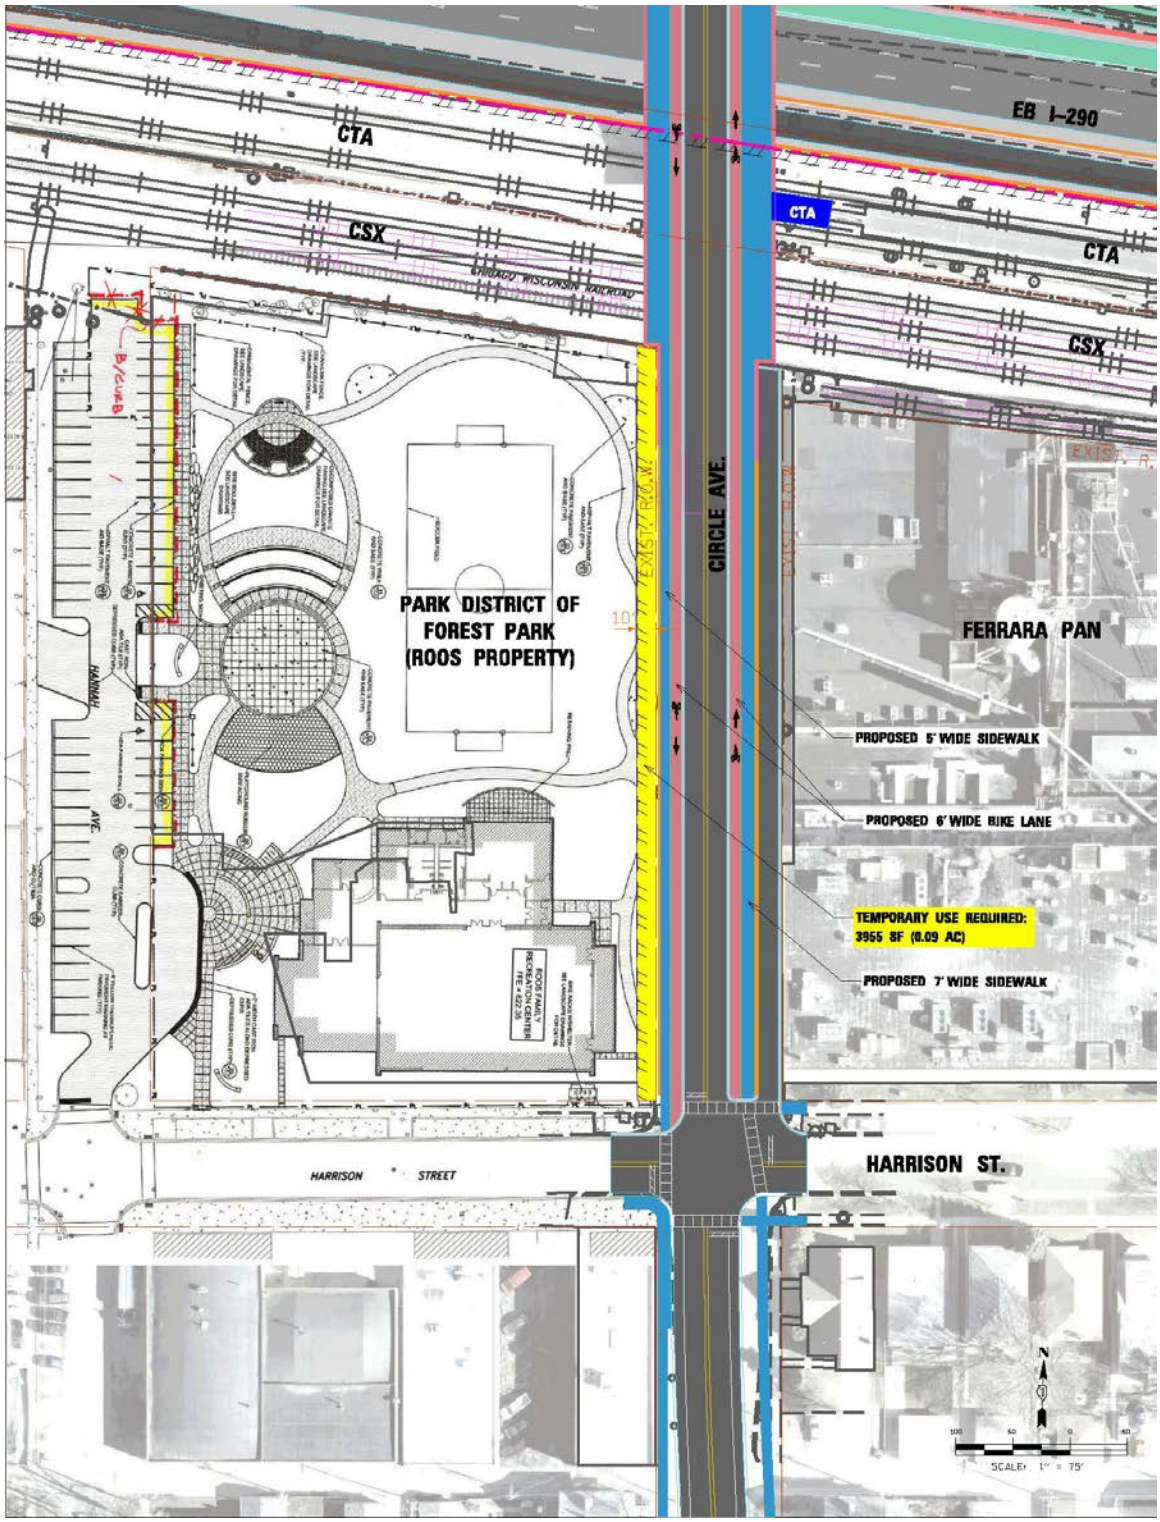


Table 3-50. Summary of Parkland Use – Village of Forest Park

Parkland Facility	Section 4(f) Involvement	Use		Comment
		Temporary	Permanent	
Veterans Park[1]	Yes	1,160 square feet (0.027 acre)	790 square feet (0.018 acre)	Two sidewalks; one each on the eastern and western perimeter
Dog Park[1]	Yes	856 square feet (0.020 acre)	575 square feet (0.013 acre)	Two sidewalks; one each on the eastern and western perimeter
Recreation Center - Roos Property[2]	Yes	3,955 square feet (0.091 acre)	-	Work space for sidewalk installation, west side of Circle Avenue
Total	Yes	5,971 square feet (0.137 acre)	1,365 square feet (0.031 acre)	

[1] Estimates based on plans dated July 11, 2016.

[2] Estimate based on plans dated March 10, 2015.

Figure 3-62. Park District of Forest Park – Roos Property

Source: WSP Parsons Brinckerhoff, 2016.

The DEIS described FHWA's intent to make a *de minimis* impact determination for Veterans Park, the Dog Park, and Recreation Center – Roos Property based on the minimization measures described. The project would not adversely impact the long-term use, function, or development of these parks. FHWA informed the Village of Forest Park, the OWJ for Veterans Park and the Dog Park, and the Park District of Oak Park for the Roos Property of its intention to make a de minimis impact determination for the parks. Through publication of the DEIS, a notice and opportunity to comment on this preliminary finding were also provided. No public comments on this preliminary determination were received, while written concurrence was received from the OWJs that the project will not adversely affect the activities, features, or attributes that make the property eligible for Section 4(f) protection.

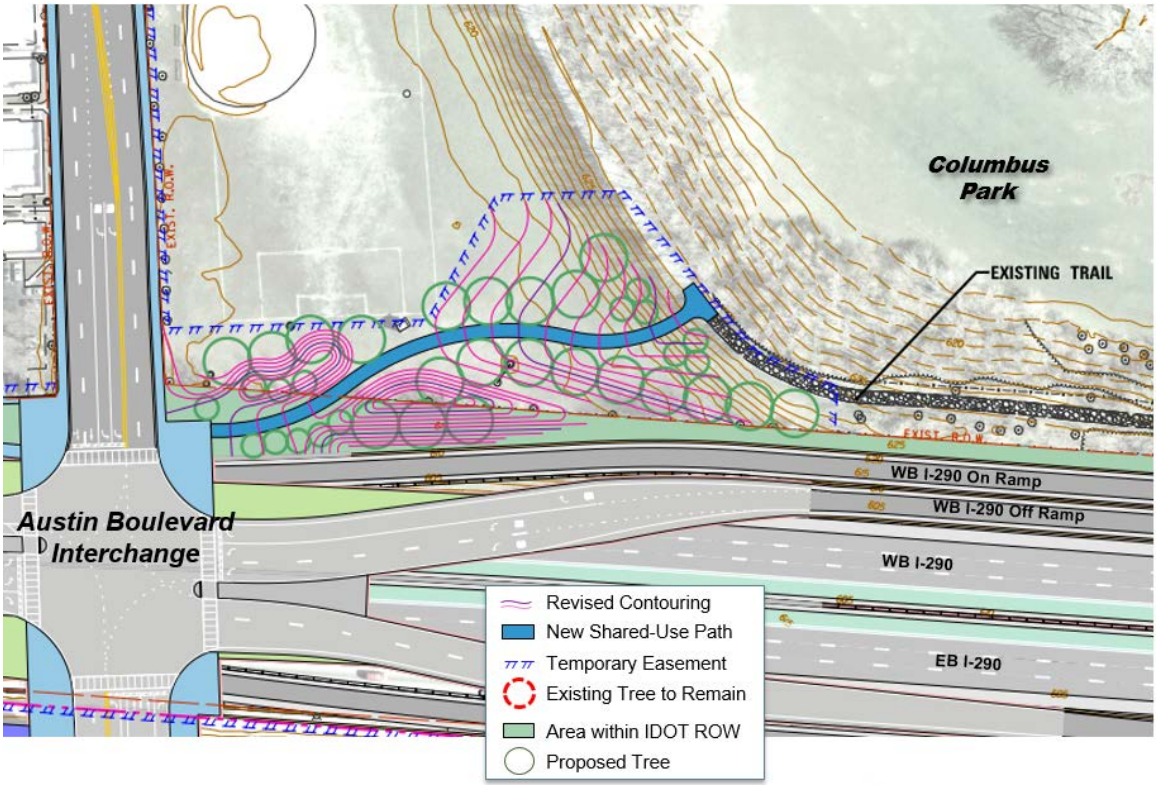
3.12.2.2 Columbus Park

The 136-acre Columbus Park sits immediately adjacent to the north side of the I-290 right-of-way between Austin Boulevard and Central Avenue in the City of Chicago. In 1953, 9 acres of the park's southern boundary were lost to make way for the Eisenhower Expressway. The park offers a wide array of amenities, including a children's playground, baseball fields, athletic fields, basketball courts, a swimming pool, a nine-hole golf course, a fishing lagoon, and pathways. In addition, there is a field house that features a fitness center, two gymnasiums, three kitchens, meeting rooms, senior center, and banquet room. Also located on the park's grounds is the "Refectory" building, which is used frequently for weddings and special events. Columbus Park was designed by noted landscape architect Jens Jensen. It was listed in the NRHP in 1991, and designated an NHL in 2003 (Section 3.2, Cultural Resources).

One objective of reconstructing the Eisenhower Expressway is to improve pedestrian access and circulation to address the need for improved modal connections and opportunities. A specific consideration, at the request of the Chicago Park District, was to enhance bicycle and pedestrian access along the southern boundary of Columbus Park between Austin Boulevard and Central Avenue north of I-290 where no connectivity currently exists. This access improvement would require work space of approximately 1.03 acres in the southwestern corner of the park to construct a 450-foot connection from the proposed shared-use path at Austin Boulevard to the park's existing trail, consequently providing continuous non-motorized access between the eastern terminus of the Illinois Prairie Path at DesPlaines Avenue to Central Avenue. For this reason, consultation with the Chicago Park District was initiated on August 19, 2015, focusing on construction of this short section of paved trail, and for other requested enhancements including earthen berms, and tree plantings along the park's southern boundary, along with a context-appropriate plaza treatment at the Austin Boulevard interchange adjoining the park's southwestern corner (Figure 3-63).

At the east end, the Chicago Park District requested reconstruction of the existing trail with grading to address drainage issues and to construct new berms for screening a portion of the expressway in the vicinity of the Central Avenue on-ramp, requiring a work space of approximately 1.71 acres (Figure 3-64). As discussed with the Chicago Park District, the east end improvements could be constructed independently or in conjunction with the reconstruction of I-290.

Figure 3-63. Columbus Park – West Side Trail Connection and Enhancements



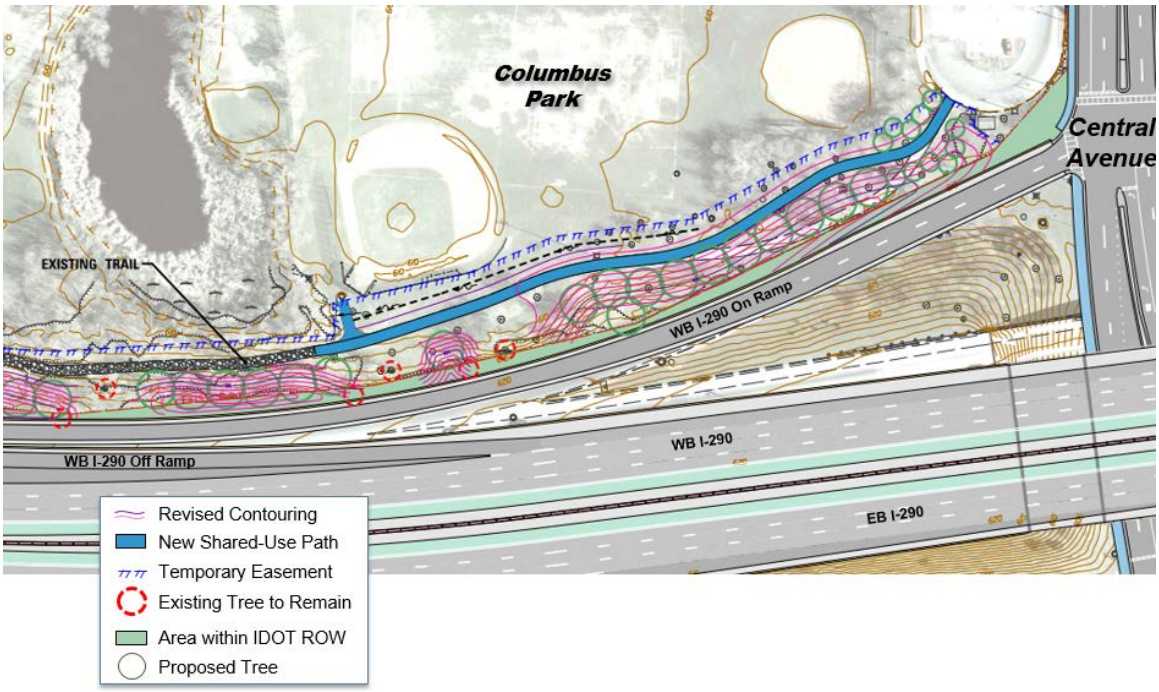


Figure 3-64. Columbus Park – East Side Enhancements

As with the Village of Forest Park parkland evaluation relative to Section 4(f) "use," the following evaluation considered permanent incorporation of land into a transportation facility, temporary use of land, and constructive use of Columbus Park by the proposed project.

Permanent, Constructive, or Temporary Parkland Use. Only temporary work space within Columbus Park would be needed. The 2.74 acres of work space would allow construction of a 450-foot-long shared-use path. As discussed previously, it would provide a connection from Austin Boulevard to the park's existing trail along the southern boundary of the park. In addition, landscape planting and earthen berms would be constructed in the vicinity of the shared-use path on the west side and along the east side as shown in Figure 3-63 and Figure 3-64. Once these enhancements are completed, the parkland would remain part of Columbus Park.

No constructive use at Columbus Park would occur because no impairment of the activities, features, or attributes that qualify the property for protection under Section 4(f) would result from activities associated with the proposed project.

Avoidance and Minimization Options. No avoidance or minimization options are available unless the shared-use path and landscape enhancements as requested by the Chicago Park District were eliminated, which would not meet the purpose and need for this element of the project, nor the design intent to improve pedestrian connectivity.

Given the benefits of the enhancements requested by the Chicago Park District and with their concurrence that these features are intended to enhance the features that qualify this property as a Section 4(f) resource, FHWA can determine that Section 4(f) does not apply if the use qualifies as an exception as defined in 23 CFR 774.13 (g). Under this exception, the improvements can be considered by FHWA as a transportation enhancement project where:

1. The use of the Section 4(f) property is solely for the purpose of preserving or enhancing an activity, feature, or attribute that qualifies the property for Section 4(f) protection; and
2. The official(s) with jurisdiction over the Section 4(f) resource agrees in writing to paragraph (g)(1) of this section.

Based on correspondence received on October 15, 2015, from the Chicago Park District (Appendix I) and informal consultation with the SHPO, the OWJs concluded that the scope of the improvements proposed would not adversely impact the park and, in fact, would preserve or enhance the activities, features, and attributes which qualify the property for Section 4(f) protection.

3.12.3 De minimis Determination for Parks within the Village of Forest Park

Three park properties in the Village of Forest Park were identified in the DEIS as potentially having a *de minimis* impact associated with the reconstruction of the Eisenhower Expressway:

- Veterans Park – permanent and temporary use
- Dog Park – permanent and temporary use
- Roos Property – temporary use

The resulting impacts to these parks would not adversely affect the activities, features, or attributes that qualify them as a Section 4(f) properties, based on the scope of the design concepts and minimization measures described previously in Section 3.12.2.1. A notice and an opportunity to comment on these proposed determinations were provided through publication of the DEIS. No comments were received from the public regarding impacts to these three parks.

The Village of Forest Park and the Park District of Forest Park (the OWJs) concurred in writing (May 18, 2017 and June 2, 2017, Appendix I) that the project would not adversely affect the activities, features or attributes that qualify the parks for Section 4(f) protection.

FHWA hereby issues a *de minimis* impact finding for the following:

- Veterans Park – 790 square feet of permanent use and 1,160 square feet of temporary use;
- Dog Park – 575 square feet of permanent use and 840 square feet of temporary use; and
- Recreation Center (Roos Property) – 3, 955 square feet of temporary use.

3.12.4 Determination of Section 4(f) Exception at Columbus Park

Certain improvements to existing and proposed pedestrian access at Columbus Park were identified in the DEIS to result in a temporary occupancy of the park. Following additional consultation with the OWJs, the scope of the proposed activities is considered to be a transportation enhancement project as defined in 23 CFR 774.13(g) and as described previously in Section 3.12.2.2. These improvements qualify as an exception to the requirement for Section 4(f) approval. The Chicago Park District and the SHPO were consulted and concurred in an exception to Section 4(f) approval based on the design concepts and measures identified previously to minimize harm to these resources (June 19, 2017 and May 26, 2017, Appendix I).

No comments were received from the public; in a written response, the US Department of the Interior requested a final opportunity to comment once the SHPO had concluded its review consistent with Section 106 of the National Historic Preservation Act. This review is required to document the project's effects on NRHP-listed and eligible historic properties which includes Columbus Park, a National Historic Landmark.

Based on the SHPO's written concurrence of a No Adverse Effect finding at Columbus Park (May 25, 2017, Appendix E), the SHPO's written concurrence with the Section 4(f) exception as a transportation enhancement project (above), and the Chicago Park District's written concurrence with FHWA's proposed Section 4(f) exception

determination (above), FHWA determines that the proposed improvements at Columbus Park requiring 2.74 acres of work space do not constitute a Section 4(f) use and that the project, once completed, would complement and enhance Columbus Park.

3.12.5 Measures to Minimize Harm and Mitigation

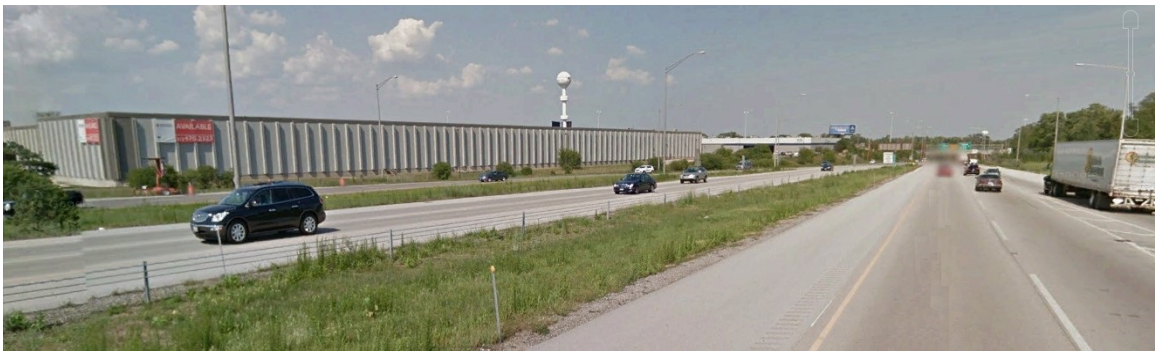
IDOT will continue to coordinate with the Village of Forest Park and the Park District of Forest Park in the pedestrian access enhancements proposed at Veterans Park, the Dog Park, and the Recreation Center – Roos Property, and with the Chicago Park District for pedestrian access and other enhancements at Columbus Park. As this consultation continues, all aspects of the final design will be approved and implemented under direction of the respective OWJs.

3.13 Visual Resources

There have been no substantive changes to this section since publication of the DEIS.

This section describes the existing visual conditions of the Project Corridor and the visual consequences of the No Build and build alternatives. The Visual Resources narrative has been organized from the following perspectives: 1) as viewed by motorists using I-290 and; 2) as viewed by occupants/users from adjacent land uses. The analysis has been further organized into five geographic sections, as identified below, using cross street locations to define each section:

- I-88/I-290 to 30th Avenue;
- 30th Avenue to 1st Avenue;
- 1st Avenue to DesPlaines Avenue;
- DesPlaines Avenue to South Central Park Avenue; and
- South Central Park Avenue to Racine Avenue.



In addition to these geographic sections, Columbus Park, Corridor Landscape, Noise Barriers, and Bridge Structures are described separately.

3.13.1 Existing Conditions Visual Analysis as viewed from the Mainline

3.13.1.1 I-88/I-290 to 30th Avenue

Land uses adjacent to the corridor at the western terminus (I-88/I-290 interchange) are largely suburban in character, consisting of large-scale commercial properties in distinct development districts. These include manufacturing, warehousing-distribution housed in large volume structures on single-owner sites, as well as stand-alone retail shops and large-scale strip center commercial developments (Figure 3-65). Commercial advertising billboards are common throughout the corridor and are a dominant element in the viewshed.

Figure 3-65. I-88 Terminus of Study Area

Commercial land uses are visible proximate to the I-88 terminus of the Study Area.

Equally dominant in this section of the corridor is the presence of residential land use, which is comprised primarily of single-family, single-lot development.

In the western portion of the corridor from approximately the I-88/I-290 interchange east to 30th Avenue, the presence of concrete retaining walls and noise barriers screen the view of the residences from the corridor (Figure 3-66). Aside from the view to roof lines and mature canopy trees beyond the right-of-way, the existing noise barriers prevent the mainline traveler from viewing the residential communities that are located proximate to the Project Corridor. In areas that are comprised of commercial or industrial land uses, generally, the areas are visible from the freeway corridor (Figure 3-67).

Figure 3-66. Western Portion of Study Area

Existing noise barriers screen views to adjacent residential neighborhoods in the western portion of the Study Area.

Figure 3-67. Mainline Roadway Views

Example of location with open views from the mainline roadway to adjacent commercial land uses.

The profile grade of the mainline roadway undulates throughout this portion of the Project Corridor. In locations where the mainline underpasses a cross street, the mainline profile is depressed in a trough. In locations where the mainline overpasses a cross street, the mainline profile tends to be on fill. The variability of the mainline roadway profile is achieved either through the use of sloped earth embankment or vertical retaining walls.

This section of the Project Corridor includes intermittent areas of vegetated landscape, which occur within medians between the mainline and parallel to the shoulder of the freeway in many locations. The plant palette outside the mainline includes native and naturalized vegetation consisting of grasses, forbs, shrubs and deciduous trees, which are not actively maintained other than what appears to be a limited maintenance

mowing along the shoulder line. Planting within the mainline medians is primarily turf grass that appears to receive regular mowing. In many locations, deciduous vines cover large portions of the noise barriers, softening their warm season appearance (Figure 3-68). The Mannheim Road interchange includes large expanses of green space within the ramp areas that are a distinct landscape feature of this corridor section (Figure 3-69).

Figure 3-68. Mainline Roadway View – Retaining and Noise Barriers

The view from the mainline is generally limited to the Project Corridor due to the presence of the nearly continuous line of retaining walls and noise barriers. Climbing vines have been planted adjacent to walls, which tend to soften their appearance.

Figure 3-69. View at Mannheim Road/I-290 Interchange

The view from the mainline of large landscape area at the Mannheim Road/I-290 interchange.

The corridor is lit at night through a combination of pole-mounted cobra head light fixtures and large-scale mast-mounted fixtures. Concrete median barriers and metal beam guard rail shoulder barriers are common features in this portion of the Project Corridor.

3.13.1.2 30th Avenue to 1st Avenue

This portion of the Project Corridor is generally characterized by residential, religious, educational, and recreational land uses. Proximate to the 25th Avenue interchange, some commercial and industrial land uses are visible but are set back from the corridor beyond the adjacent frontage roads. The 25th Avenue interchange includes large expanses of green space within the ramp areas that are a distinct landscape feature of this Project Corridor section (Figure 3-70).

Figure 3-70. View at 25th Avenue/I-290 Interchange

The view from the mainline of large landscape areas at the 25th Avenue/I-290 interchange.

The dense vegetation largely parallel to and outside the mainline in this portion of the corridor effectively screens the view from the mainline to the adjacent land uses. Occasional breaks in the planting allow limited view of the adjacent land uses; however, the general perception from the mainline is that the corridor right-of-way contains large areas of vegetation. The visual screening created by the right-of-way plantings is primarily perceived during the growing season because most of the plantings are deciduous, not evergreen (Figure 3-71). The I-290 profile grade undulates from generally at-grade for most of the section and then into a cut section proximate to locations where cross-street overpasses are located. The cut section results in some enclosure of the viewshed from the mainline. Pole-mounted lighting and concrete center median barriers and shoulder barriers are common in this portion of the Project Corridor (Figure 3-72).

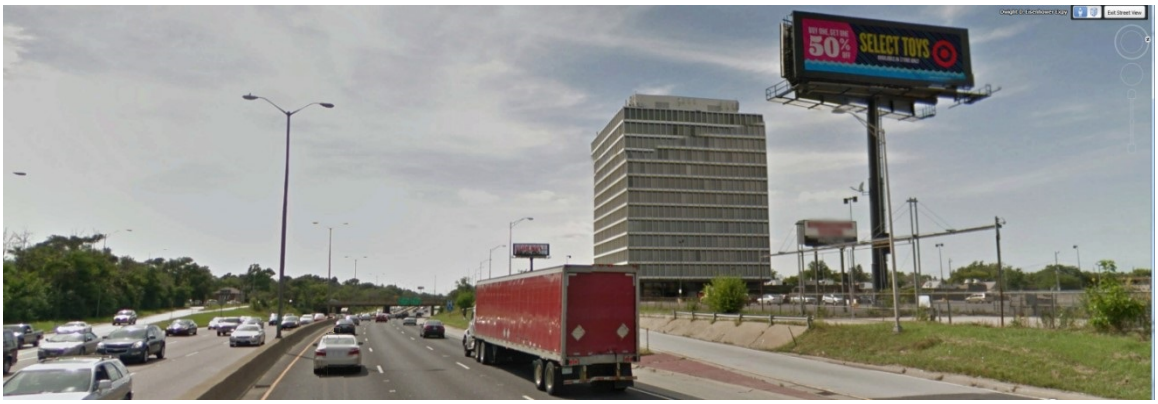
Figure 3-71. View Proximate to South 21st Avenue

Variability in the density of right-of-way planting allows occasional views to adjacent residential neighborhoods. View looking north to residences north of freeway proximate to South 21st Avenue.

Figure 3-72. Roadway View at 17th Avenue

View of roadway at cut section proximate to 17th Avenue illustrates slightly depressed roadway profile and use of concrete barriers.

3.13.1.3 1st Avenue to DesPlaines Avenue



This section of the Project Corridor has distinctly more open space character, which is formed by the presence of large tract cemetery land uses, the heavily vegetated Des Plaines River corridor, and several large office buildings and industrial storage yard land uses. The visual screening created by the right-of-way plantings is primarily perceived during the growing season because most of the plantings are deciduous, not evergreen. These elements are set back from the right-of-way and allow for open views beyond the Project Corridor (Figure 3-73 and Figure 3-74). The open view is accentuated because the mainline profile is at the natural grade for most of the length of this section. Pole-mounted lighting, concrete median barriers, and shoulder barriers are common in this portion of the corridor.

Figure 3-73. View Northeast of 1st Avenue

View beyond confines of the Project Corridor of industrial and cemetery land uses to the south and industrial storage yards to the northeast of 1st Avenue.

Figure 3-74. Mainline View near I-290/1st Avenue Interchange

Open view to high-rise office from the mainline proximate to the northeast quadrant of the I-290/1st Avenue interchange.

3.13.1.4 DesPlaines Avenue to South Central Park Avenue

At DesPlaines Avenue, the character of the Project Corridor exhibits a more urban context as the mainline profile grade returns to a cut section and is surrounded by high-density residential, industrial, and commercial properties. In addition, this section of the corridor includes heavy rail and CTA track beds, passenger ramps, platforms, and head station facilities at numerous locations. The I-290 mainline profile and rail/transit facilities are in a common cut, which allows the perpendicular cross streets to pass over on structures. Portions of the I-290 mainline corridor section include planted medians that provide physical and visual separation of the eastbound and westbound travel lanes. The distant viewshed from the mainline is contained on either side of the corridor by canopy vegetation in adjacent neighborhoods, high-density residential, commercial, and or manufacturing facilities. The near viewshed at the profile grade level is generally contained by the presence of right-of-way vegetation, retaining walls, CSX track, and CTA facilities (Figure 3-75, Figure 3-76, and Figure 3-77).

The visual screening created by the right-of-way plantings is primarily perceived during the growing season because most of the plantings are deciduous, not evergreen. Pole-mounted lighting; concrete median and shoulder barriers; and right-of-way fencing are common elements in this portion of the Project Corridor.

Harlem Avenue and South Austin Boulevard

Of special note are the I-290 interchanges at Harlem Avenue and Austin Boulevard. These interchanges have a unique visual character due to the use of paired left-hand on-/off-ramps. The left-handed configuration places the ramp pairs within the median between the eastbound and westbound main line. This arrangement is achieved through the use of paired vertical concrete retaining walls that support fill and the ramp pavement. Vertical concrete barrier walls protect the ramp lanes and further add to the height of the retaining walls flanking the main line. The presence of paired ramps and vertical retaining walls at these locations is visually unique within the Project Corridor. The viewshed from the main line is very constricted by the paired ramps as they ascend in height to the profile grade of the cross-street interchange overpasses (Figure 3-76).

Figure 3-75. CTA Facilities near Circle Avenue

A common visual element, CTA facilities and CSX rail track, are visible south of the Project Corridor proximate to Circle Avenue.

Figure 3-76. I-290 View at Harlem Avenue

Center on-/off-ramp walls (left) and CTA facilities (right) frame view along eastbound I-290 at Harlem Avenue.

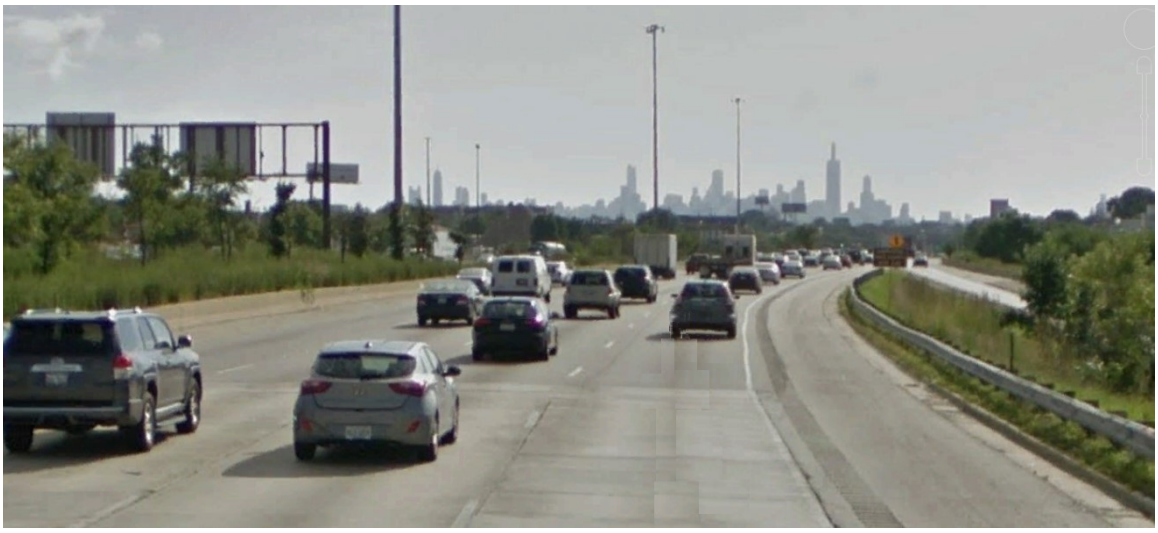


Figure 3-77. Eastbound I-290 View East of South Oak Park Avenue

Retaining walls (left), CTA facilities, and mid-rise adjacent housing structures (right) contain viewshed of the Project Corridor east of South Oak Park Avenue along the eastbound mainline.

East of Austin Boulevard, the mainline profile ascends from the cut section and becomes elevated over South Central Avenue. From this location, the eastbound motorist has the first complete view of the Chicago skyline (Figure 3-78).

Figure 3-78. I-290 Eastbound East of South Central Avenue

The Chicago skyline is visible east of the South Central Avenue overpass. Mainlines are separated by a large vegetated median (left).

This contrasts with areas farther west along the Project Corridor. The eastbound and westbound mainline in this location is separated by a wide planted median, which provides a transitional zone between the higher profile grade of the westbound lanes from the lower profile grade of the eastbound lanes and the CTA and CSX alignments. The viewshed is more open to the adjacent off right-of-way locations due in part to the adjacent Columbus Park and large-scale industrial facilities set back from the right-of-way.

The visual screening created by the right-of-way plantings is primarily perceived during the growing season because most of the plantings are deciduous not evergreen.

Between South Central Avenue and South Lockwood Avenue, the CTA track bed passes under the eastbound lanes and emerges from a tunnel aligned with the center median. From just west of South Laramie Avenue to the east end of the Study Area, the CTA facilities occupy the center median of the I-290 mainline. In addition to physically separating the mainline, the CTA facilities (i.e., head stations, platforms, and elevated track at South Paulina Street) are a dominant visual element of this section. In this section, the viewshed of the Project Corridor is defined by low-density urban environment as the buildings are in close proximity to one another but are of smaller scale and are set back from the Project Corridor. There are few exceptions to this proximate to South Kolmar Avenue and South Independence Boulevard, where large multi-story buildings are clearly visible from the corridor. The regular passing of a CTA train along the median further reinforces the urban character of the Project Corridor (Figure 3-79).

Figure 3-79. Viewshed with CTA Trains

Multi-story building east of South Independence Boulevard is a notable element in the viewshed. CTA trains travel along the central median on a frequent schedule during peak travel times.

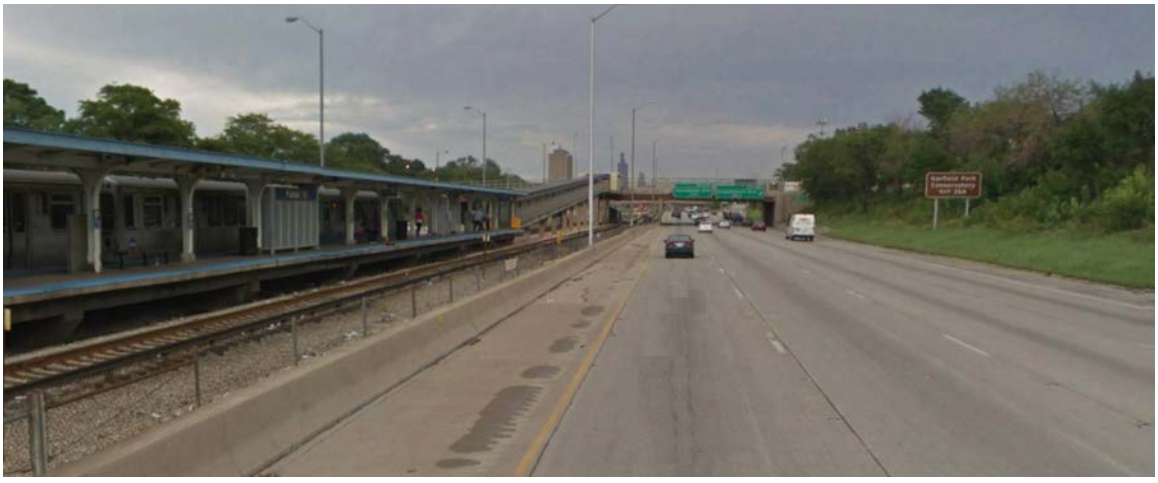
Major vegetated strips of right-of-way separate the mainline from the frontage road and generally screen the foreground views to the land uses beyond. There is less vegetation at cross street overpasses and at the on-ramp/mainline junctures, allowing for more open views to the adjacent urban fabric. The CSX track alignment also shifts south and away from the I-290 viewshed.

3.13.1.5 South Central Park Avenue to Racine Avenue

East of South Central Park Avenue, the viewshed from the mainline is characterized by an increasing urban density, as observed from the west to east. The section exhibits many urban land uses, including light industrial, commericial, institutional, education, civic, medical, parks and open space, and residential. The immediate viewshed of the corridor varies primarily as a result of the mix and scale of these land uses and the close proximity of CTA facilites co-located within the Project Corridor (Figure 3-80 and Figure 3-81). The distance viewsheds vary from open to contained and are reflective of the size composition and height of the developments immediately adjacent to the right-of-way (Figure 3-82 and Figure 3-83). The perimeter of the right-of-way parallel to the mainline is generally vegetated with deciduous trees, shrubs, and turf, which provide some screening and buffering of the adjacent land uses from the Project Corridor. The visual screening created by the right-of-way plantings is primarily perceived during the growing season because most of the plantings are deciduous, not evergreen.

In several locations, the landscape is formal and highly maintained as a result of a sponsored landscape program by various corporations and institutions. The urban character is most fully developed in the corridor section located east of Western Avenue, which includes large educational facilities, high-density housing, office spaces, and multiple mid and highrise structures that make up the Illinois Medical District (Figure 3-84).

Figure 3-80. I-290 Eastbound near South Damen Avenue

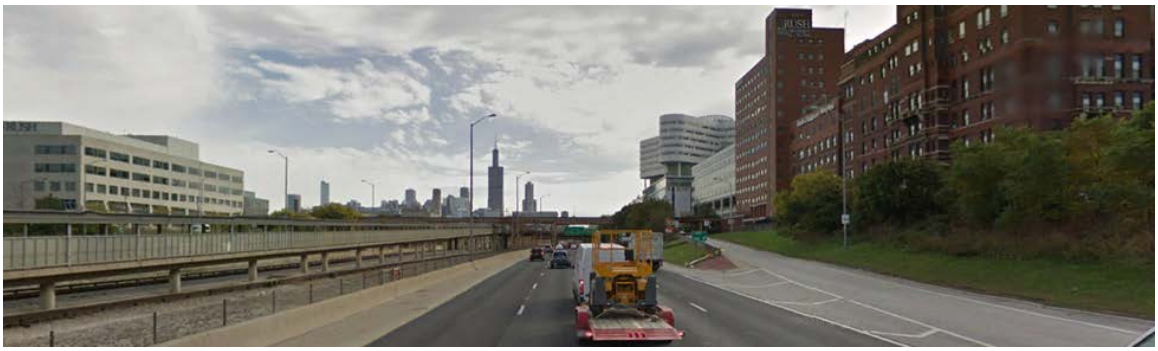


Viewshed of corridor appears generally suburban in character with vegetation parallel to right-of-way. Occasional land uses with large buildings interrupt otherwise open distant viewshed. Eastbound mainline proximate to South Damen Avenue.

Figure 3-81. I-290 Mainline View East of South Central Park Boulevard

Viewshed of corridor becomes more urban in character east of South Central Park Boulevard. Frequent occurrence of large buildings interspersed with apartments and institutional land uses form the distant viewshed.

Figure 3-82. I-290 Eastbound West of South Pulaski Road



CTA facilities are a dominant visual element in the median separating the main lanes of the Project Corridor east of South Laramie Avenue.

Figure 3-83. Eastbound Mainline View West of South Paulina Street

CTA facilities are a dominant visual element overpassing the eastbound mainline.

Figure 3-84. Eastbound I-290 Mainline View

High-density urban character proximate to South Paulina Street is indicative of eastern end of the corridor. Viewshed is highly restricted.

3.13.2 Viewsheds of the Project Corridor from Adjacent Land Uses

3.13.2.1 I-88/I-290 Interchange to 30th Avenue

From the I-88/I-290 interchange east to 30th Avenue, the view from the adjacent residential land uses is screened due to the presence of noise barriers (Figure 3-85). Conversely, the views to and from the commercial, institutional, and industrial facilities are generally open and only limited by vegetation located adjacent to or on the right-of–way (Figure 3-86).

The existing noise barriers are generally located along right-of-way, accompanied by landscape areas of varying widths. In some locations, the planted space is on the side facing the I-290 mainline, and in others, it is located on the outside of the wall nearest the adjacent land use (Figure 3-87).

Figure 3-85. View at Hillside Avenue/Jackson Boulevard

View of freeway right-of-way and associated noise barrier at Hillside Avenue/Jackson Boulevard north of freeway.

Figure 3-86. View from Frontage Road east of Hillside Drive

Open southwest view to frontage road and freeway beyond from Hotel Property located east of Hillside Drive along north frontage road.

Figure 3-87. Southwest View Proximate to Hillside Drive

View looking southwest of planted embankment and noise barrier along north frontage road proximate to Hillside Drive. Planting is between noise barrier and frontage road.

The extent and quantity of the landscape in these strips varies depending on the available space. In larger spaces, large groupings of shrubs, trees, and grasses are common. In narrower strips, planting may include a single row of trees and turf or just turf. Vines have been planted along the base of the walls in many locations, which provides visual softening of the walls as viewed from outside the right-of-way (Figure 3-88).

Figure 3-88. View Looking East near Harrison Street

View looking east of wall with vines, low shrubs, and turf along south frontage roadway near Harrison Street west of Orchard Street.

In commercial, industrial, and similar land use locations, only right-of-way and off right-of-way landscapes separate the view of the corridor from these uses. In these locations, the view of I-290 is variable, from completely open where no planting exists, to entirely screened where dense plantings have thrived (Figure 3-87). The dominant plant types are deciduous, which provides a higher level of visual screening during the growing season. In the dormant season, the views are more open, allowing the walls and freeway (where walls do not exist) to be more visible from the adjacent land uses.

3.13.2.2 30th Avenue to 1st Avenue

In this portion of the Project Corridor, the right-of-way between the mainline and the adjacent frontage roadways is predominantly vegetated. The density and quality of the vegetation varies but generally provides semi-continuous screening of views from the frontage roads to the Project Corridor. The screening afforded by the plantings varies depending on the season of the year, slope, width, and density of the planting. A majority of the plantings tend to be deciduous and afford most of the screening properties during the growing season. The plantings vary from very dense and sight-proof to sparse with little screen value to only turf, which allow open views to the freeway. The open view locations are largely in the vicinity of on- and off-ramp facilities. Other areas that have sparse or little vegetation include locations where the roadway

facilities consume most of the right-of-way, leaving less room for soil in which to support plantings and areas adjacent to commercial properties (Figure 3-89, Figure 3-90, Figure 3-91, and Figure 3-92). In most locations, views are possible from one side of the freeway corridor to the other, most notably in locations where plantings are less dense and are comprised of primarily deciduous or warm season plant species.

Figure 3-89. I-290 Mainline near Cernan Drive

View of right-of-way with sparse planting proximate to Cernan Drive.

Figure 3-90. View along Harrison Street

Deciduous plantings screen views to the Project Corridor looking southeast along Harrison Street proximate to 2nd Street.

Figure 3-91. View of Bataan Drive near 23rd Avenue

Planting screen views from south frontage road to adjacent freeway common to many locations.

Figure 3-92. North Frontage Road along Harrison Street

Relatively open views to the Project Corridor from north frontage road at ramp facility along Harrison Street proximate to 19th Avenue.

3.13.2.3 1st Avenue to DesPlaines Avenue

In this portion of the Study Area, the mainline profile is predominantly at-grade and is bounded by the surrounding land uses of institutional (cemetery), industrial services, and mid-/high-rise offices. The views from these land uses vary from open to limited views in locations where dense right-of-way vegetation is located (Figure 3-93).

Figure 3-93. View Looking East near 1st Avenue

Open view to the Project Corridor looking east along north frontage road east of 1st Avenue.

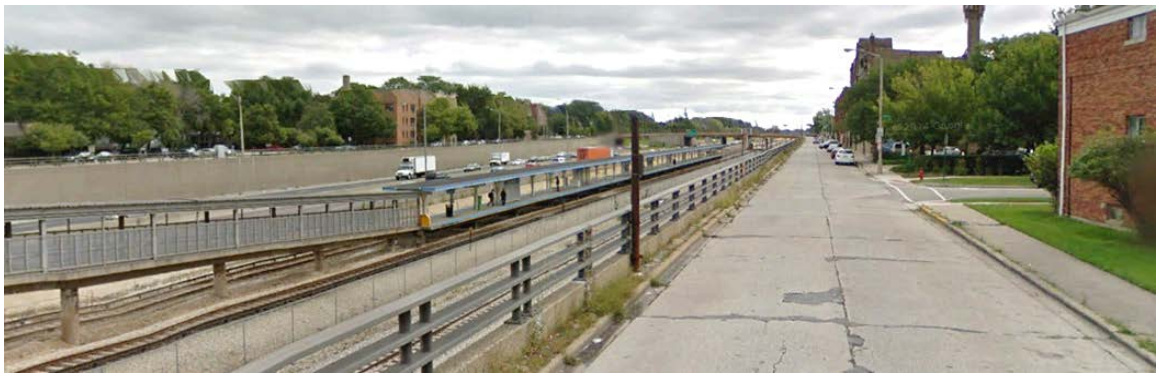
3.13.2.4 DesPlaines Avenue to South Central Park Avenue

This section of the corridor is located in an excavated trough, resulting in the surrounding land uses developed at a consistently higher elevation than the Project Corridor. The resulting viewshed from these adjacent land uses includes the foreground (Project Corridor), but more notably the land uses located across the corridor. The character of the adjacent viewsheds varies from residential to mixed use, reflecting the differing land uses located in this section of the corridor. In most locations, views are possible from one side of the freeway corridor to the other, most notably in locations where plantings are less dense and are comprised primarily of deciduous or warm-season plant species.

3.13.2.5 South Frontage DesPlaines Avenue to South Central Avenue

From DesPlaines Avenue to Home Avenue, recreational, industrial, and commercial land uses border the Project Corridor and block direct view of the corridor from the adjacent frontage street and surrounding residential neighborhoods. The large recreational facilities that abut the Project Corridor are generally screened from viewing the Project Corridor due to grade separation, existing vegetation, and screen fence/wall. The industrial and commercial properties have limited views of the Project Corridor because they tend to be sited to face the adjacent frontage street or cross streets. East of Home Avenue, along Garfield Street, views of the Project Corridor and across to the land uses beyond are generally open because little or no landscape plantings exist within the right-of-way in this portion of the Project Corridor.

3.13.2.6 Home Avenue to South Central Avenue



East of Home Avenue the balance of the Project Corridor along the south side of this section is comprised of residential, institutional, and recreational land uses with isolated commercial buildings located at the corners of major cross streets and the frontage road. The view to the Project Corridor from these land uses generally consists of one of the following two conditions. The first condition includes a turfed landscape strip with regularly spaced tree plantings bounded along the edge with a metal rail fence (Figure 3-94). The second condition consists of a concrete curb with metal barrier rail, which is located at the edge of the frontage road and has no planted space (Figure 3-95). The views of the Project Corridor east of South Menard Avenue to South Central Avenue are blocked by large industrial facilities. In most locations, views are possible from one side of the freeway corridor to the other, most notably in locations where plantings are less dense and are comprised primarily of deciduous or warm-season plant species.

Figure 3-94. View to I-290 from Garfield Street

View of the Project Corridor looking north through planted tree lawn adjacent to Garfield Street.

Figure 3-95. Northeast View to I-290 from Garfield Street

View of the Project Corridor looking north through vehicle barrier adjacent to Garfield Street.

3.13.2.7 DesPlaines Avenue to Austin Boulevard North Frontage

The character of the Project Corridor along the north frontage road generally consists of residential land uses separated from I-290 by a vegetated strip of right-of-way. The strip varies in width, and the density of the vegetation varies depending on the location. Wider right-of-way strips are generally denser, while narrower strips typically have less dense vegetation. The right-of-way is bounded by a nearly continuous chain-link fence. The fence is located on grade except where a retaining wall abuts the frontage road, where it is located on top of the wall. In several locations, there is a wooden screen fence parallel to the chain-link right-of-way fence (Figure 3-96, Figure 3-97, Figure 3-98, Figure 3-99, and Figure 3-100). The view from the adjacent land uses varies depending on location. In some locations, wide landscape areas provide nearly complete screening of the Project Corridor. In other locations, wood fencing screens some of the views to the adjacent corridor. The height of this wood fence varies from location to location. In other locations, the landscape strip is very narrow, and a metal safety rail is used in place of the chain-link fence, permitting open views to the freeway. In most locations, views are possible from one side of the freeway corridor to the other, most notably in locations where plantings are less dense and are comprised primarily of deciduous or warm-season plant species.

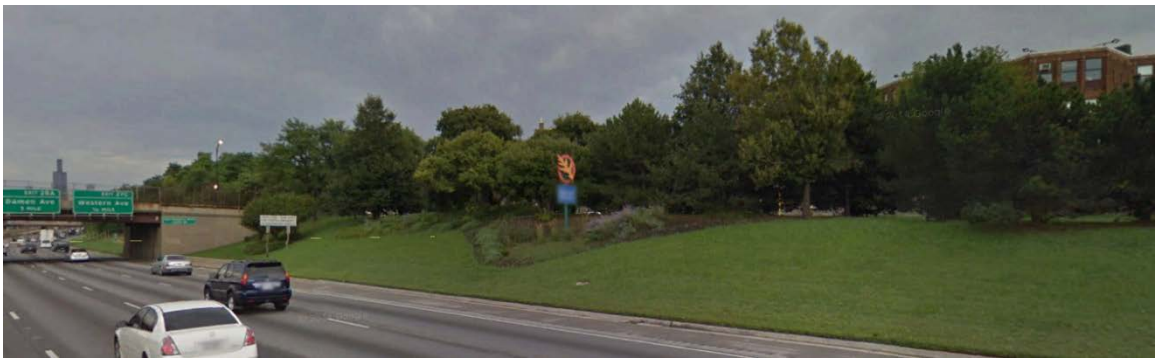
3.13.2.8 South Central Park Avenue to Racine Avenue



This section of the Project Corridor is highly urbanized containing a broad range of land uses. As a result, the views from the adjacent frontage roads are highly variable depending on the adjacent land use and the condition of the right-of-way. The viewshed of the Project Corridor from the adjacent land uses generally includes a vegetated strip of right-of-way separating the frontage road from the ramps and mainline facilities. These vegetated strips vary widely in condition from native and naturalized in appearance comprised of grasses planted, volunteer tree plantings (receiving little or no regular maintenance), to pockets of formal plantings with masses of shrub and perennial planting in formal beds with groupings of trees that receive routine maintenance and have a manicured appearance. The formal manicured landscapes are the exception and tend to be sponsored by commercial entities, institutions, or are part of a park property. These less frequent formal landscapes present a distinct character different than most of the Project Corridor. The majority of the Project Corridor consists of variable conditions largely determined by the density and height of the landscape planting within the right-of-way. As a general condition, the right-of-way is separated from the adjacent frontage road with a chain-link fence. The fencing varies in condition from very good to poor. This element also impacts the view character along this section of the Project Corridor (Figure 3-101, Figure 3-102, Figure 3-103, Figure 3-104, Figure 3-105, and Figure 3-106). In most locations, views are possible from one side of the freeway corridor to the other, most notably in locations where plantings are less dense and are comprised of primarily deciduous or warm-season plant species.

Fencing and hedge row planting along right-of-way of West Flournoy Street, East of South Laramie Avenue.

Figure 3-106. View from West Flournoy Street at Kilpatrick Avenue

Larger right-of-way landscape area separate frontage road from mainline West Flournoy Street at Kilpatrick Avenue.

3.13.3 Columbus Park

The Project Corridor abuts the City of Chicago's Columbus Park along the park's southern boundary. Views of the I-290 westbound off-ramp at Austin Boulevard are partially visible from the soccer field located in the southwest corner of Columbus Park and from locations along the paved trail that borders the southern edge of the park east of the soccer fields (Figure 3-107). Mature vegetation along the south park boundary and within the right-of-way only partially obscure some of the view to the ascending retaining wall, traffic barrier, and vehicles of the westbound off-ramp at Austin Boulevard. The original Jens Jensen design incorporated berms and plantings at the park's perimeters as a principal element in his Prairie-style philosophy. These elements are still intact along the central portion of the southern park perimeter and provide notable visual separation from the existing expressway improvements as viewed from the existing shared-use path. The view of the freeway from the paved trail located along the south edge of the park parallel to the I-290 right-of-way varies from limited visibility

just east of the soccer field to complete view proximate to the ball fields at the eastern end of the park (Figure 3-108, Figure 3-109, Figure 3-110, Figure 3-111, and Figure 3-112). The viewshed from the adjacent park land north of the trail has a limited view of the traffic along the mainline. The views from the golf course to the Project Corridor are very limited due to the amount and density of the vegetation located within the park and along the Project Corridor right-of-way (Figure 3-109). In addition, the park site is lower in elevation than the mainline profile grade, which further reduces views of the freeway from the golf course. As the trail approaches the center of the park, the grade between the adjacent mainline and the trail becomes more similar. The view of the mainline becomes more open and apparent from this location to the east end of the park. At the southeast corner of the park, the softball fields and eastern end of the trail have generally open views to the freeway. The westbound on-ramp at South Central Avenue begins at park grade and ascends to meet the profile grade of the westbound mainline, which is higher in elevation than both the trail and the ball fields (Figure 3-110, Figure 3-111, and Figure 3-112). The existing planting along the park perimeter in this area is of insufficient density to screen the view to the freeway.

Figure 3-107. View at I-290 Off-Ramps at Austin Boulevard

Existing vegetation within the I-290 right-of-way partially obscures the view to I-290 off-ramps at Austin Boulevard from soccer field (right) and trail (left) in the southwest corner of the park.

Figure 3-108. View at Columbus Park Trail

Existing vegetation along the Columbus Park trail at a lower grade than the adjacent freeway reduces visibility to the Project Corridor (left).

Figure 3-109. Columbus Park Trail on South Edge of Columbus Park

3.13.4 Environmental Consequences

3.13.4.1 No Build Alternative

The visual character of the corridor with the No Build Alternative would remain essentially unchanged because no additional facilities would be added to the Project Corridor. It is possible that maintenance-related improvements would be undertaken to aged infrastructure, which would positively affect the visual character of corridor elements. This would likely include repair and replacement of retaining walls, bridge decks, barrier railings, right-of-way fencing, and similar corridor elements. It is likely that some improvements may be made to pedestrian facilities on the cross-street overpass bridges and CTA transit facilities, which also may have some minimal positive effect on the existing visual character of the Project Corridor.

The environmental consequences of the build alternatives from a visual perspective vary considerably along the Project Corridor. Table 3-51 identifies the various sections of the corridor and the types of improvements and anticipated visual impact the improvements would have on that portion of the Project Corridor. Those locations where visual character of the corridor would remain essentially as it is today have been identified as having no impact, and no specific narrative is included concerning them.

Table 3-51. Impacts to Visual Resources within and from outside the Project Corridor

Location of Visual Resources	Impact to Viewshed anticipated
As Viewed from within the Project Corridor	
I-88/I-290 to 30th Avenue	Roadway, bridge
30th Avenue to 1st Avenue	Roadway, bridge and noise barrier
1st Avenue to DesPlaines Avenue	Roadway, bridge
DesPlaines Avenue to South Central Park Avenue	Roadway, bridge and noise barrier
South Central Park Avenue to Racine Avenue	Primarily due to noise barrier
As Viewed from outside the Project Corridor	
I-88/I-290 to 30th Avenue	No impact
30th Avenue to 1st Avenue	Primarily due to noise barrier
1st Avenue to DesPlaines Avenue	Primarily due to noise barrier
DesPlaines Avenue to South Central Park Avenue	Primarily due to noise barrier
South Central Park Avenue to Racine Avenue	Primarily due to noise barrier

3.13.4.2 Visual Consequences of Build Alternatives as viewed from within the Project Corridor

General Corridor Description

While the proposed reconstruction of the Project Corridor varies as described below by location, in those sections that would be reconstructed, an effort would be made to create a consistent corridor aesthetic. While the final design is yet to be completed, the general appearance of walls, noise barriers, bridge piers, and fencing is anticipated to include the textures and forms illustrated in Figure 3-113 through Figure 3-116.

The magnitude of reconstruction varies within the Project Corridor. The images in Figure 3-113 through Figure 3-116 are representative of those portions of the corridor that would receive total reconstruction.

Sub-area Descriptions

I-88/I-290 to 30th Avenue

The viewshed of the Project Corridor, from the motorist's perspective within this area, would be altered due to the addition of travel lanes and shoulders. At the I-88/I-290 interchange, the lane additions would be accomplished by removal of portions of the turf-covered center medians. Along the north edge of the right-of-way proximate to North Wolf Road, the widening of the pavement and bridges would be accomplished beyond the existing shoulder within the right-of-way. While the corridor would be modified to accommodate the added lanes, the impact on the viewshed would be minimal because the proposed improvements would appear similar to the existing conditions. Depending on the method of lane management, there may be toll/tag monitoring facilities added to the Project Corridor that are not currently present. These facilities would alter the viewshed accordingly. The general location, height, and character of retaining walls and noise barriers are anticipated to be similar and would mirror the existing condition when completed. As stated in Section 3.6, Natural Resources, efforts would be made to preserve existing vegetation wherever possible. Where plantings must be removed, they would be replaced per IDOT policy.

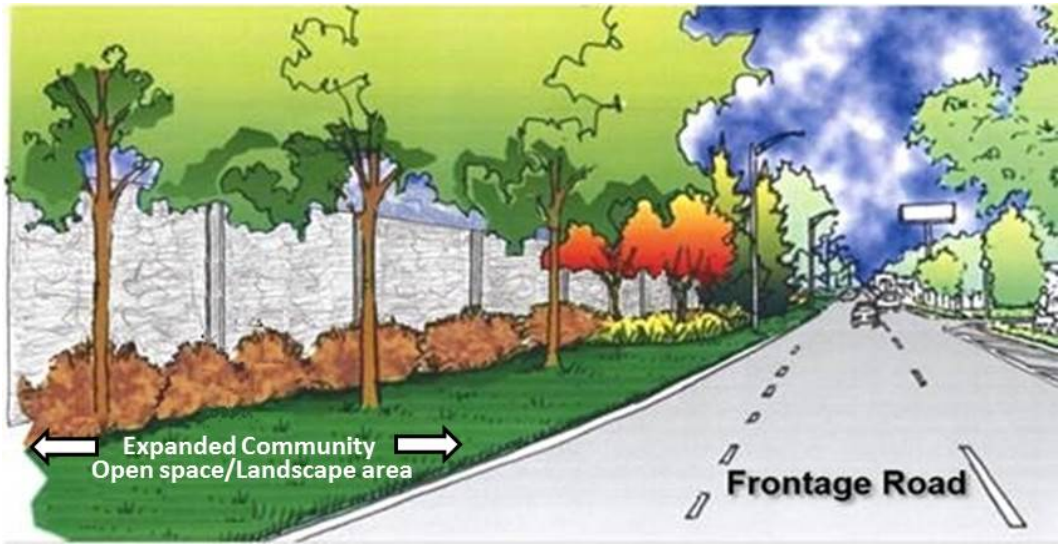
Between Mannheim Road and Suffolk Avenue, the proposed improvements would occur within the existing right-of-way. The pavement would be widened along the outside edge of the existing facility. The existing noise barrier on the north and the existing retaining wall/noise barrier along the south perimeter would remain in place. The impact of the addition of travel lanes in this portion of the Project Corridor would be limited to the increase of pavement and the corresponding decrease in perimeter landscape area.

East of Suffolk Avenue and proximate to Addison Creek on the north, and between Suffolk Avenue and Bristol Avenue on the south, the noise barriers would be relocated within the right-of-way to allow widening of the freeway. The relocation of these walls would tend to open the viewshed and make this portion of the Project Corridor appear more similar to the adjacent westerly section. The loss of a portion of the existing plantings between the existing walls and the freeway would change the character of the viewshed in this part of the Project Corridor.

Along the north edge of the Project Corridor, the pavement would be expanded outside the existing retaining wall. Upon completion, the retaining walls, noise barriers, and plantings would be restored per IDOT policy.

Along the south edge of the Project Corridor, no changes to the existing conditions are proposed; therefore, the viewshed along the south perimeter would not change.

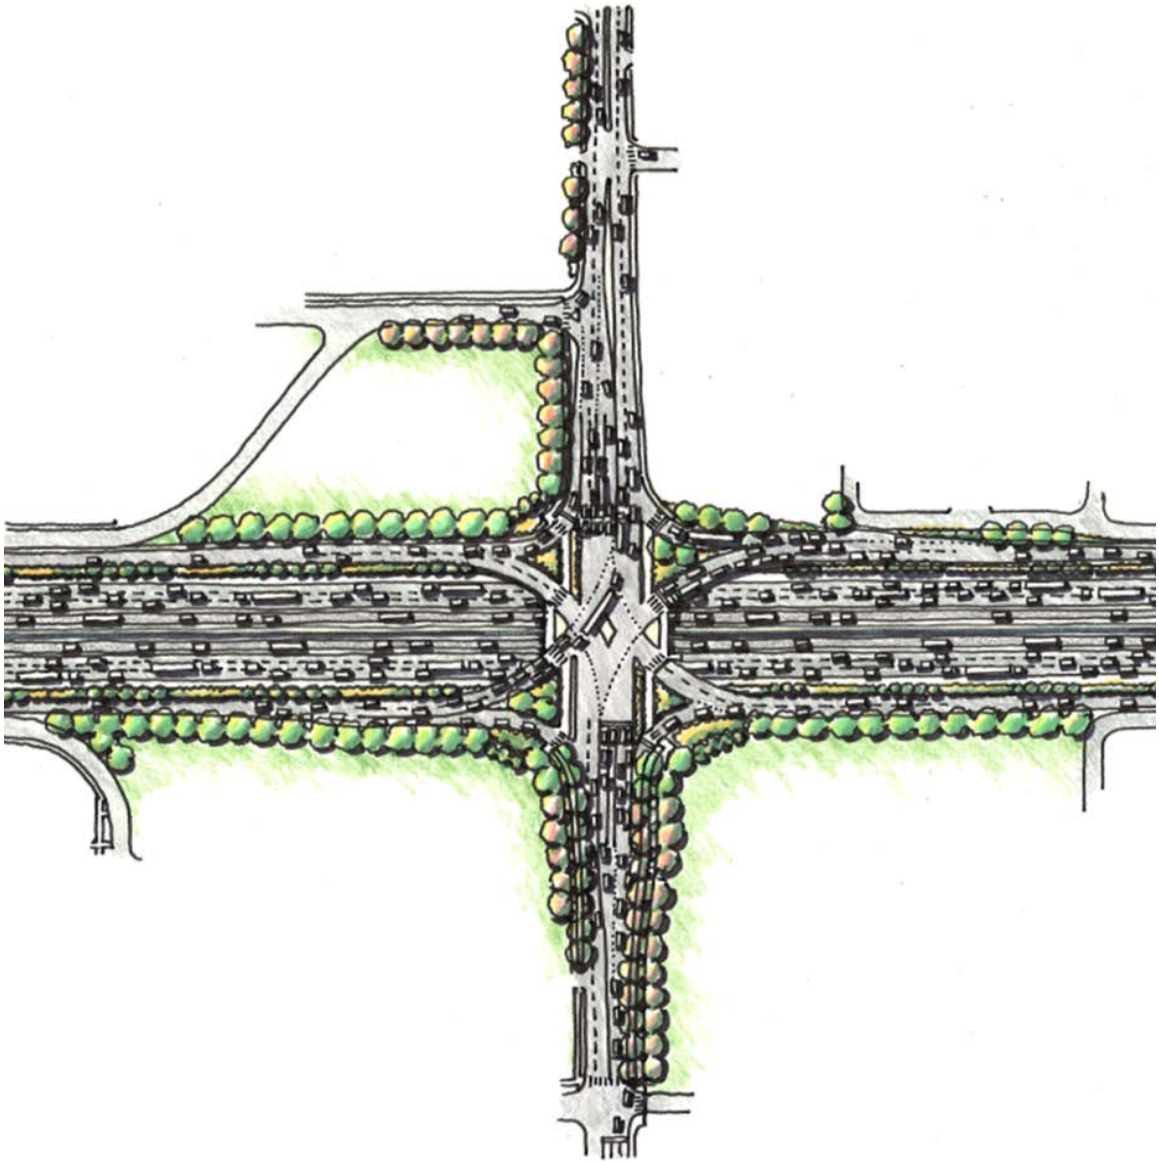
30th Avenue to 1st Avenue



The portion of the corridor would undergo several significant changes that would alter the visual character of the corridor. Realignment of sections of the frontage roads west of 25th Avenue would allow reconfiguration of the 25th Avenue interchange from a cloverleaf to a SPUI. This conversion would change the appearance of the corridor from

the existing conditions. The changes would primarily result from removal of landscape areas parallel with the existing shoulder and replacement with on-/off-ramps. In addition, the 25th Avenue SPUI overpass bridge structure would be wider than the existing 25th Avenue bridge, and the mainline traveler would pass under a significantly larger bridge deck.

The on-/off-ramps east of the interchange would be located parallel and adjacent to the mainline, and existing landscaped right-of-way would be removed to facilitate these ramp placements. New retaining walls would be needed to accommodate the ramps in these locations and would further alter the viewshed east of the 25th Avenue interchange. The existing loop ramps would be removed, and the areas currently occupied by the ramps would be open space.



Between the 25th Avenue and 1st Avenue interchanges, the character of the corridor would change as travel lanes are added to the center and shoulders, and ramps would be reconfigured along the exterior. To accommodate the additional lanes, space for a future transit extension along the median, ramp reconfiguration, and retaining walls would be constructed along the north and south sides of the expressway within the existing right-of-way. The retaining walls would replace the existing vegetated slopes, preserve the existing elevations of the frontage roads (Harrison Street and Bataan Drive) beyond, and add additional community-level greenspace area between the frontage roads and retaining walls (Figure 3-117).

Figure 3-117. Frontage Road Community-Level Space

In addition, all cross-road bridges in this segment (17th, 9th, and 5th avenues) would be replaced with slightly wider bridges to accommodate improved sidewalk widths. These wider bridges would alter the visual character from the mainline traveler. The collective result of the above improvements would markedly alter the visual character from an aged suburban-appearing facility to a more contemporary, urban one (Figure 3-118).

Figure 3-118. 25th Avenue

Schematic landscape plan of right-of-way plantings in 25th Avenue interchange. Final planting design to be determined with input from local community.

1st Avenue to DesPlaines Avenue

At 1st Avenue, a SPUI interchange is proposed. All of the same character issues described at 25th Avenue apply to this interchange. While the entire interchange would be reconfigured, most of the interchange reconfiguration can be accomplished within the right-of-way with some required in the northeast quadrant to accommodate a relocation and improvement of the westbound I-290 to 1st Avenue off-ramp. The southeast and southwest quadrants would include reconfiguration of ramps within the right-of-way with a reduction in landscape area over the existing condition. This would alter the visual character of the corridor proximate to the interchange due to a wider 1st Avenue

bridge over I-290, as well as a wider expressway to accommodate the additional through lanes and the provision for future transit guideway along the median of I-290.

Between the east end of the 1st Avenue interchange and the DesPlaines Avenue interchange, most of the expansion would occur along the north side of the freeway. This edge of the corridor is characterized by gentle sloping terrain toward the freeway with dense brush and pole-mounted commercial billboards at 500-plus-foot intervals. The proposed improvements would result in the removal of a portion of the existing vegetation along the north right-of-way. While the number of travel lanes would increase, the general character of the viewshed area would remain similar to the existing condition. Proximate to the DesPlaines Avenue interchange, existing retaining walls would be reconstructed on both sides of the freeway to facilitate a widened bridge and the expanded travel lanes. While these walls would replace existing walls, the introduction of new walls and a new overpass structure at DesPlaines Avenue would alter the visual character of this part of the corridor.

DesPlaines Avenue to South Central Park Avenue

Between DesPlaines Avenue and Circle Drive, the improvements would occur within the confines of the existing right-of-way. The conversion of a large center median (partially paved and partially turf covered) provides space for the lane expansion. The balance of the improvement is facilitated by the insertion of retaining walls along the outside edges of the Project Corridor. This would require the removal of existing plantings along the near edge of the north right-of-way. The viewshed in this part of the corridor would be altered in that mainline traffic would now only be separated by a concrete median barrier, and reduced landscaped space also would be apparent. The freight railroad overpass bridges and Circle Avenue bridge also would be replaced, which would provide the opportunity for visual improvement of the corridor.

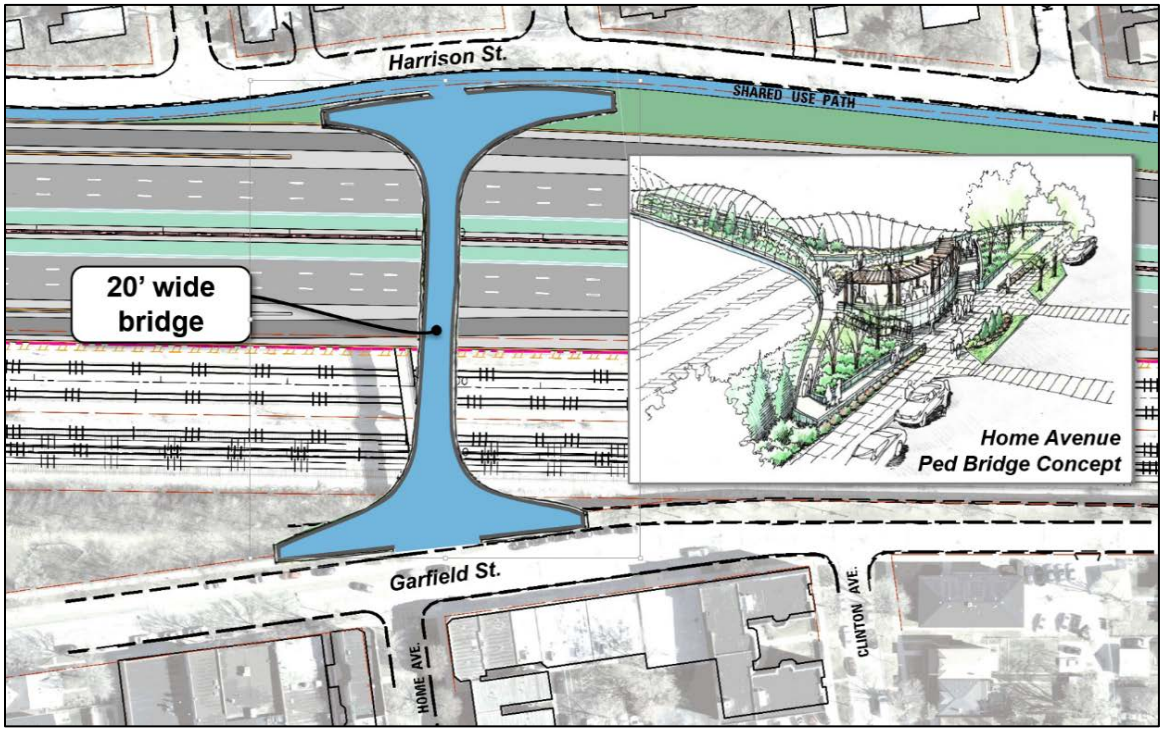
Harlem Avenue and Austin Boulevard

The proposed interchange improvements from left-hand ramp to right-hand ramp configuration at these two locations would transform the current visual character as viewed from the mainline (Figure 3-119 and Figure 3-120). Harlem Avenue and Austin Boulevard would be converted to the modified SPUI-style interchange and retain the existing ramp intersection over the center of the expressway. The modified SPUI interchange is possible by bridging over the mainline with a series of regularly spaced support structures known as straddle bents. The use of straddle bents would be new to the Project Corridor and would be a noticeable change to the viewshed as observed from the mainline. Additionally, the on-/off-ramps depart from the mainline along the right-hand side of the Project Corridor and then curve over the top of the mainline, which would be a notable difference from existing structures in the viewshed.

Figure 3-119. Harlem Avenue Interchange

Aerial perspective of proposed Harlem Avenue Interchange.

Figure 3-120. Austin Avenue Interchange



Aerial perspective of proposed Austin Avenue Interchange.

The Village of Oak Park is planning to undertake aesthetic investments at Harlem Avenue and Austin Boulevard, including decorative light poles, decorative fencing, planters, decorative arching gateway feature, and decorative paving or stone sidewalks.

Between Circle Drive and Austin Boulevard, the Project Corridor would be altered through the replacement of all bridge structures. The balance of this portion of the Project Corridor would include replacement of the following bridges: Home Avenue (Pedestrian Bridge), South Oak Park Avenue, South East Avenue, South Ridgeland Avenue, and South Lombard Avenue. One noticeable visual difference is that the crossroad bridge decks would be wider than the existing structures. The additional width would be due to the construction of 12-foot-wide sidewalks across both sides of the bridges, except in front of CTA Blue Line Stations where sidewalk widths would be 16 feet.

The Village of Oak Park is planning to incorporate various levels of aesthetic improvements along the reconstructed cross-street bridges. The existing Home Avenue pedestrian bridge would be reconstructed as a 20-foot-wide bridge along which Village Oak Park intends to construct a linear park and trail over the expressway (Figure 3-121).

Figure 3-121. Home Avenue Pedestrian Bridge

At Oak Park Avenue, the Village also is planning to make an aesthetic investment as a signature bridge along their commercial district. Improvements being considered are decorative lighted arches, decorative light poles, decorative railings, and planters. A concept the Village cited as an example is shown in Figure 3-122.

Figure 3-122. Oak Park Signature Bridge Concept

The accommodation of additional expressway travel lanes would be accomplished by the reuse of existing center medians and space formerly occupied by the left-hand ramps, with additional space created by the relocation of existing retaining walls primarily between the outside edge of the existing north shoulder and the north right-of-way line. The walls would vary in height and proximity to the westbound travel lanes. The final width and architectural character of the reconstruction of the overpass bridges also would affect the character of the viewshed.

The Village is planning to incorporate more modest aesthetic treatments along East Avenue, Ridgeland Avenue, and Lombard Avenue. Treatments under consideration include decorative lighting, painted or stone sidewalks, limited landscaping and planting at entry points, and potentially an arching feature at Ridgeland Avenue.

Between Austin Boulevard and approximately 1,000 feet east of South Central Park Avenue, the proposed lane improvements would replace the existing wide vegetated center median.

South Central Park Avenue to Racine Avenue

East of South Central Park Avenue, the relocation of on-/off-ramps between South Laramie Avenue and South Cicero Avenue would alter the viewshed as some landscaped right-of-way would be replaced with pavement. The balance of the Project Corridor from just east of the South Cicero Avenue interchange to the Racine Avenue interchange would sustain visual impacts because noise barriers are proposed to be installed along significant portions of the right-of-way. Other improvements would be of less impact and are comprised of signing and pavement striping. There is the possibility that many of the existing bridge structures in this portion of the Project Corridor would

be renovated and refurbished, which also would potentially affect the visual character of the Project Corridor as viewed from the mainline.

3.13.4.3 Visual Consequences of Build Alternatives as viewed from outside the Project Corridor

The quality and character of the existing viewsheds of the Project Corridor as viewed from the adjacent land uses are a result of the original I-290 construction. The former contiguous views along city streets were altered when the freeway was first constructed. Since that time where sufficient right-of-way permitted, vegetation has filled in these voids and provides varying levels of screening of portions of the I-290 corridor primarily during the growing season. While density and quality of vegetation vary widely, the existing vegetation does affect the ability to view one side of the corridor from the other where the right-of-way is wider and the vegetation is the densest. The primary visual consequence of the build scenarios as viewed from outside the corridor would be the loss of this vegetation and the placement of noise barriers. To mitigate for this loss, the retaining walls and other structures would be located such that the maximum amount of green space is created between the new retaining walls and the adjacent off-corridor land uses. Where space permits, landscape planting would be installed to restore the lost vegetation and to soften the appearance of the noise barriers. Section 3.13.5.2 describes such areas in more detail. A series of existing and post-construction visualizations depicting the landscape and noise barriers may be found in Appendix J.

I-88/I-290 to 30th Avenue

The views to the Project Corridor would remain essentially as they are today as most of the improvements would be constructed behind the existing noise barriers. As a result, the viewers from behind the existing barriers would not observe any changes in viewshed. Those land uses that are not currently located behind a noise barrier would observe minor changes in the viewshed as travel lanes and other associated improvements may be altered from the existing conditions. These alterations are minor and would alter the viewsheds only slightly and would have no or little adverse impact.

30th Avenue to 1st Avenue

The view to the Project Corridor in this section would be altered in that noise barriers along the expressway that have been deemed reasonable and feasible, and subsequently voted on by those who would benefit from a wall, are proposed to be installed. Exceptions include the northwest and southwest quadrants of the 25th Avenue interchange where noise barriers have been deemed to be not feasible. The viewshed in this area also would be altered because of the reconfiguration of the mainline and cross-street bridges.

The noise barriers in this section of the corridor are anticipated to be 13 to 17 feet tall, which would block the view from and to adjacent land uses on the opposite side of the Project Corridor (Figure 3-123). The mainline viewshed also would be impacted because these viewsheds would be contained by the presence of the noise barriers. As is often the case, visual preferences among stakeholders vary. Certain stakeholders may consider the proposed noise barriers as undesirable, while others may prefer the noise barrier, the benefits of reduced noise levels, and the expanded landscape areas over the naturalized and existing unmaintained vegetation in the corridor. A viewpoint solicitation survey was conducted to determine which noise barriers would be implemented along the corridor. Noise barriers are discussed in Section 3.13.5. During the design phase, the noise wall viewpoint solicitation may be revised to respond to potential changes in stakeholder opinions and to accommodate any new acceptable noise wall materials, such as transparent (acrylic) applications.

Figure 3-123. Noise Barrier Visualization – Village of Westchester

Simulation of potential noise barrier as viewed from Wedgewood Bridge at Bristol Avenue, Village of Westchester.

In addition, views along cross-street overpasses within this portion of the Project Corridor would change as new bridge decks, railings, fencing, sidewalks, and lighting would be constructed. These elements would tend to create positive visual impacts over the existing conditions.

1st Avenue to DesPlaines Avenue

The insertion of noise barriers in this portion of the Project Corridor has been deemed to not be cost effective or reasonable; therefore, no new visual impact would result to this section of the corridor as viewed from the surrounding land uses. In addition, views along cross street overpasses within this portion of the Project Corridor would change as new bridge decks, railings, fencing, sidewalks, and lighting would be constructed. These elements would tend to create a positive visual impact over the existing conditions.

It is possible that as new technologies are developed and additional research is completed that new design concepts for noise barriers could be employed in portions of the Project Corridor.

DesPlaines Avenue to South Central Park Avenue

The viewshed to the Project Corridor in this section would be altered in that noise barriers have been deemed reasonable and feasible to parallel the travel lanes along nearly the entire north side of the corridor (except along Columbus Park). Similarly, most of the south frontage road has been deemed reasonable and feasible for the addition of noise barriers (except between DesPlaines Avenue and Harlem Avenue). Wall heights along this portion of the Project Corridor are anticipated to be between 13 and 17 feet, which would essentially block the view from adjacent land uses to the Project Corridor and prevent views across the corridor (Figure 3-124). The mainline viewshed also would be affected because these viewsheds would be contained by the presence of the noise barriers. Noise barriers are discussed further in Section 3.13.5.

Figure 3-124. Noise Barrier Visualization – Village of Oak Park

Simulation of potential noise barrier as viewed from Flournoy Street and Austin Boulevard, Village of Oak Park.

In addition, views along cross-street overpasses within this portion of the Project Corridor would change as new bridge decks, railings, fencing, sidewalks, and lighting would be constructed. These elements would tend to create a positive visual impact over the existing conditions.

South Central Park Avenue to Racine Avenue

The viewshed to the Project Corridor in this section would be altered dramatically in that noise barriers have been deemed feasible to parallel the travel lanes along most of the corridor (exceptions include intermittent omission of noise barriers proximate to commercial and industrial land uses abutting north and south right-of-ways). Noise barriers are anticipated to be between 13 and 17 feet in height, which would essentially block the view from adjacent land uses to the Project Corridor and prevent views across the corridor (Figure 3-125). The mainline viewshed also would be impacted because these viewsheds would be contained by the presence of the noise barriers. Noise barriers are discussed further in Section 3.13.5.

Figure 3-125. Noise Barrier Visualization – City of Chicago

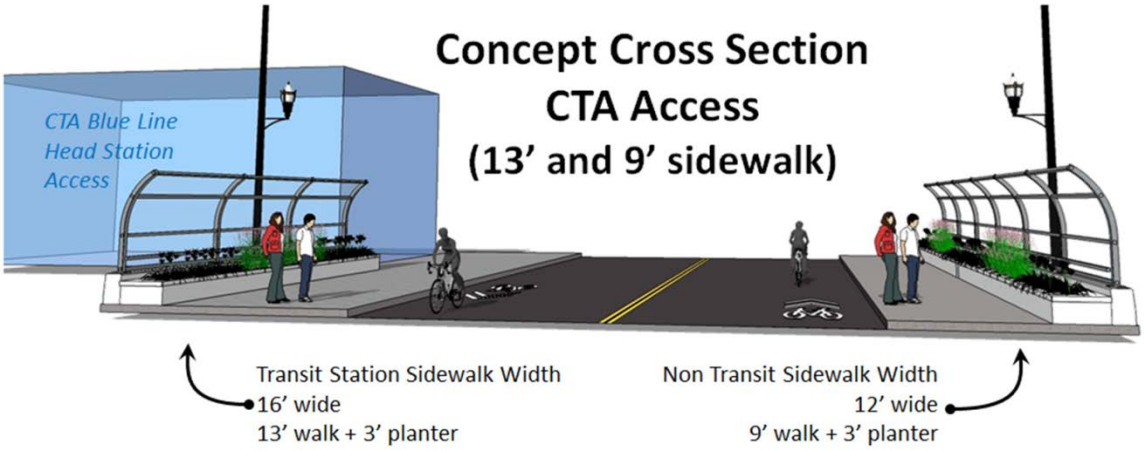
Simulation of potential noise barrier as viewed from Congress Street and Denvir Avenue, City of Chicago.

Bridge Structures

All cross-street overpass bridges from 25th Street to Austin Boulevard would be reconstructed as part of this project. It is anticipated that the bridge replacements would be of standard IDOT design with a central structural support or bent located between the main travel lanes and intermediate bents within the rail portion of the corridor similar to the existing structures. The reconstruction would provide the opportunity for the new bridges to be constructed with a common aesthetic treatment, providing a uniform visual character for the bridges in this section of the Project Corridor from the perspective of the expressway user. A uniform aesthetic treatment would be applied to the substructure and outward-facing elements, including abutment walls, parapets, and piers. In addition, local communities have the opportunity to further enhance the bridge rails, fencing, and lighting of the cross-street bridges within their jurisdiction, such as Oak Park is planning for the bridges within their community. These potential enhancements could further improve the visual character of the Project Corridor as viewed from the main lanes and cross-street interchange locations.

Cross-street bridge deck widths would vary between one another depending on the number of required travel lanes, bicycle accommodations and sidewalk widths, and accessory streetscape improvements agreed upon by local communities at each cross-street location. As shown in Figure 3-126 and Figure 3-127, the width of the structures and corresponding sidewalk would also be increased to provide improved access and circulation at CTA transit stations. The width of new bridge decks would be greater than the existing bridges and may be noticeable from the main travel lanes. The inclusion of dedicated bike lanes and wider sidewalk widths would be readily apparent to the cross-street bridge users. Expanded cross-street bridge deck widths would provide a more consistent path of travel for pedestrians from one side of the expressway to the other, improving the physical and visual connection between the neighborhoods located on either side of the Project Corridor. These improvements would improve the visual character of the Project Corridor compared to the existing condition.

Figure 3-126. Typical Cross-Street Section View with CTA Station



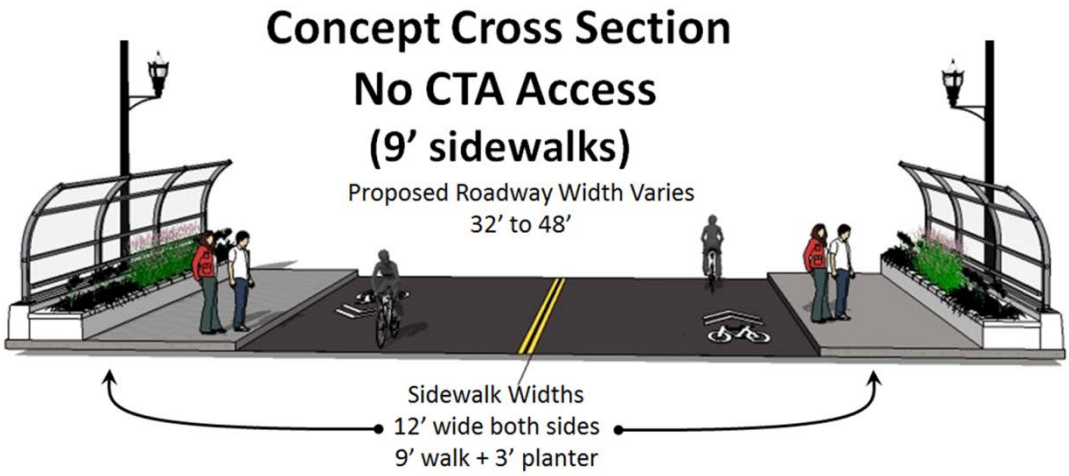


Figure 3-127. Typical Cross-Street Section View without CTA Station

CTA would also be modernizing the Blue Line street-level head house stations along the cross roads and the track-level platforms. A street-level head house concept proposed at Ogden Avenue follows in Figure 3-128. Similar concepts are likely to be considered at other locations along the Blue Line in the Project Corridor.

Figure 3-128. CTA Blue Line Head Station Concept

3.13.5 Mitigation

Mitigation of the visual consequences of the build alternatives can be accomplished by several approaches, as described below.

3.13.5.1 Context Sensitive Design

This method of planning and facility design extends beyond the physical transportation design requirements using a more holistic approach to the design by understanding and identifying the key context and the visual character elements of the surrounding communities in which the improvements are made and applying these character elements to features of the new construction. Context sensitive design may include community inputs into physical planning, as well as provide insight into relevant forms, textures, colors, and public art suitable for incorporation into surfaces of retaining walls, noise barriers, cross-street overpasses, and ramp structures. When combined, this input can provide a visual continuity to the Project Corridor for the mainline traveler, as well as unique identity at cross-street overpasses for each affected community.

Additional attention can be given to the integration of the facility into the fabric of the adjacent communities at the neighborhood level. Emphasis of the context can be focused on a full multimodal approach to the cross-street overpass structures by providing adequate space for pedestrians, street furnishings, bike share facilities, lighting, way-finding, and landscape components. Incorporation of these contextually appropriate accommodations on cross-street overpasses may require greater surface area than the functional space allocations customarily designed. The schematic layouts for new cross-street overpasses in the Project Corridor have been designed to accommodate many of these elements, which will result in a visually pleasing and functionally appropriate solution.

IDOT is committed to working closely with local communities along the Project Corridor to identify key character elements for the communities that can be incorporated into the facility planning and aesthetic treatment of the various infrastructure elements.

This approach has the potential to improve the visual character and physical cross-street connection of one side of the corridor to the other. In some locations, financial participation by local communities may be required to achieve the level of visual enhancement requested by stakeholders.

3.13.5.2 Landscape Improvements

The use of landscape improvements can provide many benefits to reconstruction of the Project Corridor. These include visual enhancement through plant forms, seasonal bloom and foliage color, softening of rigid structural elements, visual framing, and screening of portions of the corridor from another. The introduction of new I-290 landscape improvements will be undertaken in the following manner.

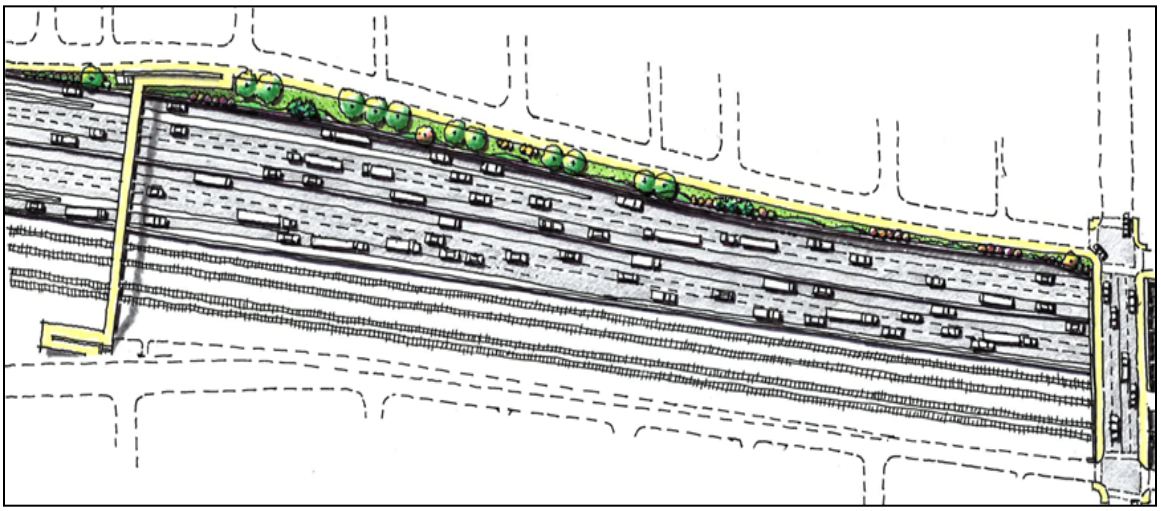
Replacement of Existing Landscape

IDOT is committed to including tree replacement as part of the I-290 reconstruction and will do so consistent with IDOT policy for size and type of trees that are removed as a result of new construction. Refer to Section 3.6, Natural Resources, for a detailed description of the tree inventory and replacement for the proposed project.

The existing landscaped portion of the Project Corridor along the north edge of the right-of-way would be altered in many locations to allow for the addition of travel lanes and improvements to ramp geometrics, retaining walls, trail facilities, and noise barrier construction. While these landscape areas would be reduced in width, the insertion of a short barrier and or retaining wall in many locations would provide additional space for a future landscaped area atop the wall. In the process of constructing the ramps, retaining walls, and noise barriers it is anticipated that most, if not all, of the existing landscape in the right-of-way in these locations would need to be removed and replaced. Removal of the semi-mature landscape and the reduction in landscape area would be noticeable to mainline travelers until such time as the landscape is replanted and attains substantial growth. Similarly, removal of the existing landscape would alter the current viewsheds as viewed from the adjacent land uses.

Where feasible, narrow planting strips would be placed at the foot of the new retaining walls and/or noise barriers in which vines may be planted. In time, the vines would cover the walls and provide softening and some visual character and seasonal interest similar in effect to the existing retaining walls/noise barriers at the western end of the Study Area. In some locations, new retaining walls would be intentionally located adjacent to the mainline. This would facilitate the placement of new landscape areas at-grade and adjacent to the frontage road. This would allow the landscape to provide visual screening of the freeway and noise barriers from the adjacent neighborhoods. This has the potential to positively impact the view of the Project Corridor from the adjacent land uses.

While the insertion of a shared-use path along the north edge of the right-of-way from Austin Boulevard west to DesPlaines Avenue would reduce the existing vegetation within the north edge of the right-of-way, it would provide a beneficial nonmotorized facility to the corridor. The trail alignment, as planned, meanders along the north edge



of the right-of-way to preserve adequate space for a renovated landscape on one or both sides of the trail alignment. In a few locations, the trail would be located on or directly adjacent to the frontage road, and no space would be available for new landscape.

Creation of New Landscape Areas

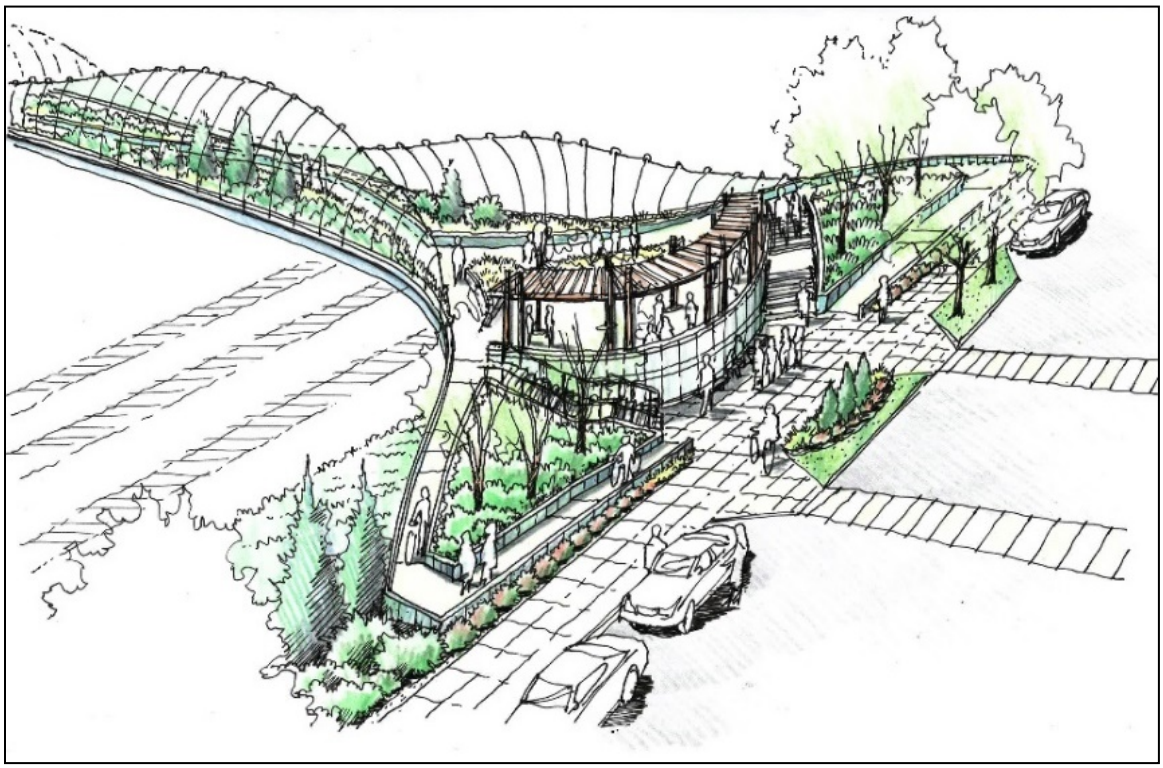
In larger areas within the right-of-way, the opportunity exists for a large expanse of new landscape to be created. These spaces are available to meet the required replacement of landscape plantings and to address special local community desires for landscape enhancement. Opportunities for such landscape areas are along the north right-of-way at the Home Avenue Pedestrian Bridge (Figure 3-129 and Figure 3-130) and Ridgeland Avenue (Figure 3-131 and Figure 3-132). Plantings would be installed as part of the project, with maintenance undertaken by local communities under an agreement with IDOT.

Widening bridge decks beyond functional requirements can allow for the addition of planter boxes, special lighting, seating, and other amenities on bridges that would enhance the comfort and safety of users and the visual character of the Project Corridor and the surrounding community.

Figure 3-129. Home Avenue Pedestrian Crossing

Schematic landscape plan of right-of-way plantings between north end of Home Avenue Pedestrian Bridge (left) and Oak Park Drive overpass (right). Plantings are to be placed at top of slope and readily visible from the adjacent neighborhood.

Figure 3-130. Home Avenue Pedestrian Bridge Concept



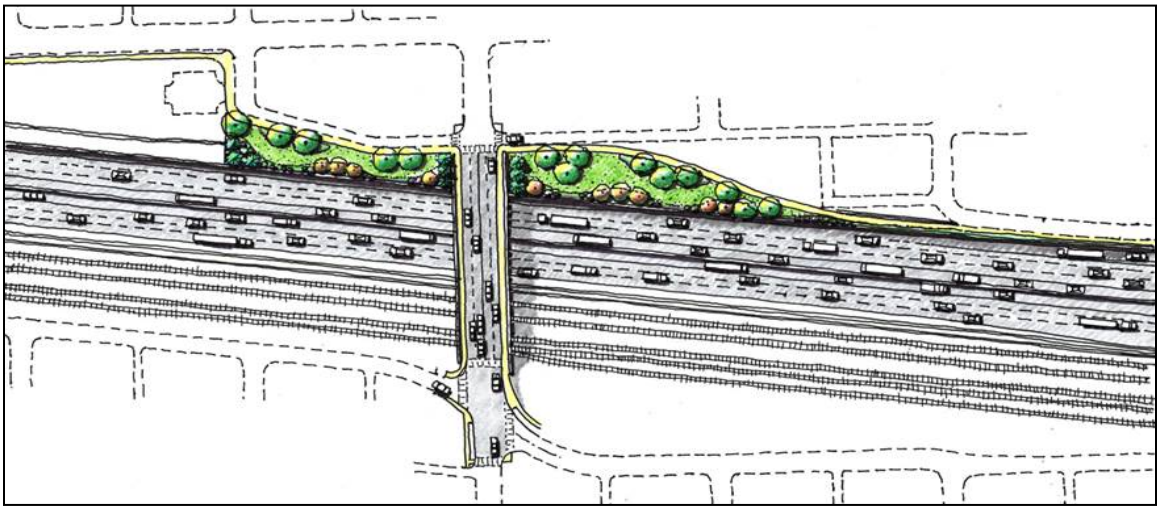


Figure 3-131. Ridgeland Avenue Schematic Landscape Plan

Schematic landscape plan of right-of-way plantings east and west of north end of Ridgeland Avenue overpass. Plantings are to be placed at top of slope and readily visible from the adjacent neighborhood.

Figure 3-132. Concept Design – Ridgeland Avenue Overpass

Image of cross-street overpass (left), retaining wall, fencing, and landscape (right) along north I-290 right-of-way at Ridgeland Avenue. Note: Landscape is at frontage road height and readily visible from the adjacent neighborhood beyond.

Containerized Landscapes

In addition to large contiguous landscape plantings on right-of way, the opportunity exists for seasonal plantings to be included within planter boxes and containers located on the cross-street overpass bridges (Figure 3-133). The preference to include plantings on overpass structures will be coordinated with the local units of government to ensure there is an agreement in place for the cost to plant and maintain these container landscapes.

Figure 3-133. Overpass Planter Boxes

Partial Image of cross-street overpass with shared bike lane, sidewalk, planter box, lighting, and safety fencing.

3.13.5.3 Noise Barriers

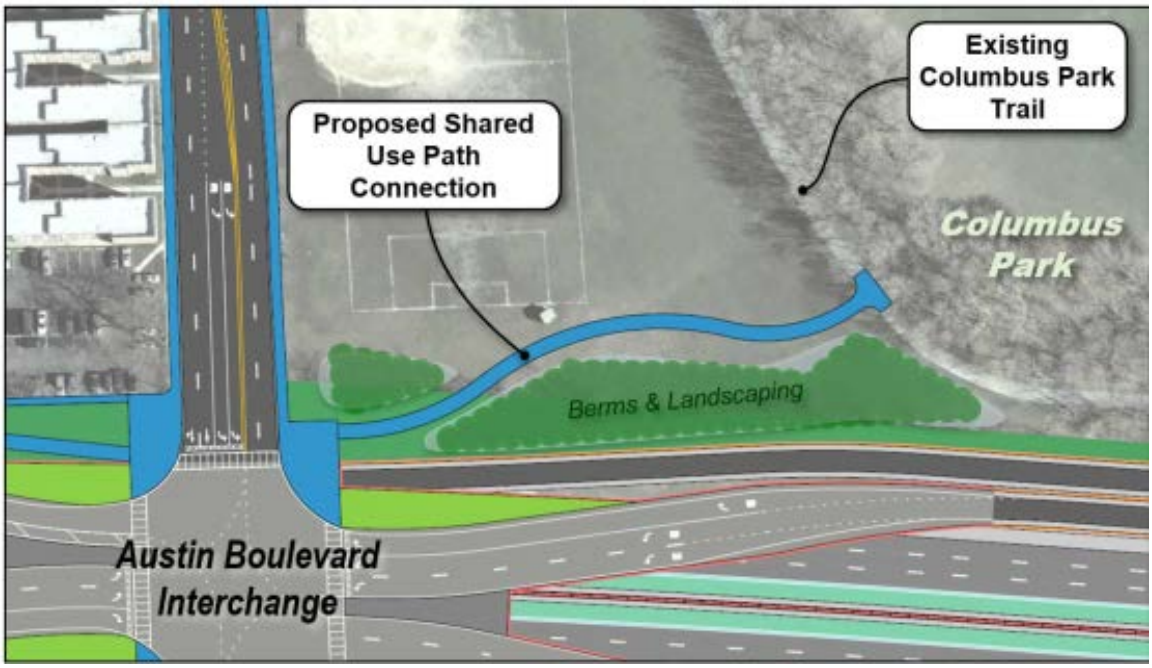
As part of the planning and design process, IDOT completed a traffic noise assessment of the Project Corridor to identify locations where noise barriers may be warranted. The height, length, and location of noise barriers were based on the results of the traffic noise analyses completed, identification of noise impacts, and consideration of noise abatement where feasible and reasonable. Section 3.4, Traffic Noise, includes a more detailed description of the traffic noise assessment process and results.

IDOT recognizes that noise barriers would be a new built element in the Project Corridor and considers them another potential opportunity to provide visual enhancement to the mainline and adjacent land uses. As such, IDOT is open to the innovative use of traditional and new materials for noise barrier construction and will work with local communities to select the most appropriate material(s), character, and finishes for barriers with the local context. To achieve the ultimate desired character and aesthetic requested by the stakeholders, local financial participation may be required.

Figure 3-134 depicts an illustration of base design character for the noise barriers to be added to the Project Corridor. See Appendix J for additional visualizations of noise barriers at specific locations along the Project Corridor.

Figure 3-134. Noise Barrier Visualization Base Design Character

Perspective view of opaque post and panel-type noise barrier. Aesthetic surface treatment is one of many possible options and is shown for general illustration purposes.



In support of the viewpoint solicitation process for feasible and reasonable noise barriers, a series of visualizations have been prepared for 15 locations along the corridor. The visualizations represent the view from the adjacent land use toward the Project Corridor of the proposed noise barrier in the planned location and heights as determined by the noise analysis. An existing conditions image is provided for context and comparison along with a visualization of the proposed improvements. The aesthetic surface treatment on the noise barrier is exemplary of what is achievable within the standard IDOT design process.

The use of solid opaque materials, as shown, is currently the most affordable and feasible option. However, in the future other less visually obtrusive solutions also may become cost effective, providing the necessary noise abatement while limiting the visual impact to adjacent land uses along the Project Corridor. Transparent materials, such as acrylic, offer potential solutions to areas where preservation of existing viewsheds is preferred and noise reduction also is desired. IDOT intends to conduct additional discussions with local community stakeholders during the project's design phase to determine the aesthetic treatment that is most appropriate for each community. To achieve the ultimate desired character and aesthetic requested by the stakeholders, local financial participation may be required.

3.13.5.4 Columbus Park Trail Connection

IDOT has coordinated with the Chicago Park District to provide a shared-use path connection on the west end of Columbus Park near Austin Boulevard, at their request. Included as part of the proposed project, this path connection would be complemented by other visual enhancements along the south edge of the park at this location, including additional park-level green space, earthen berms, and tree plantings (Figure 3-135). Along the east side of the park, near Central Avenue, similar aesthetic improvements are also proposed, including berms and new plantings. These enhancements, individually and together, would provide an improved viewshed to and from the park.

Figure 3-135. Columbus Park Trail Connection

The concept design for the shared-use path connection incorporates earth berms between the path and the adjacent I-290 improvements and also between the open field area of the park and the path connection proposed to Austin Boulevard. The use of earth berms and tree plantings is consistent with the original Jens Jensen plan to create a sense of enclosure for the perimeter of the park, which is still intact along the adjacent west end portions of the south park perimeters. See Section 3.12, Special Lands, for more detailed discussion of enhancements proposed to Columbus Park.

3.14 Construction Impacts

Since the publication of the DEIS, the following substantive changes to this section have been made:

- Updated Section 3.14.1.2 to reference a communications plan to notify local communities of project construction activities and offer opportunities for stakeholder feedback; and
- Updated Section 3.14.3 to reference additional guidelines for the preparation of a project-specific dust control plan during construction.

Construction impacts generally would be of short duration and end shortly after project completion. The expected short-term impacts associated with the build alternatives are identified below.

3.14.1 Transportation

Construction of any of the build alternatives for I-290 would take place over several years, and during this time, some traffic is anticipated to divert away from I-290 due to lane reductions and mainline construction activities. Because I-290 serves regional and local traffic, regional and local travel diversions would occur. At the regional level, some users who use I-290 as a connection between Chicago and points west are anticipated to divert to other regional expressways such as I-55 and I-90/I-94, or use alternate transportation provided by the regional commuter rail system (Metra). At the local level, some users of local expressway trips are anticipated to divert to the local parallel arterials or use alternate transportation provided by local bus and HRT services (Pace and CTA). Ample capacity is available on Metra and CTA rapid transit to accommodate diversions to the public transit system.

3.14.1.1 Advance Work

Potential advance work improvements were identified to facilitate local and regional travel during construction, accelerate mainline construction timeline, reduce the overall duration of mainline construction impacts, and assist in the general distribution of programming costs. Advance work elements were considered based on the following strategies:

- Off-system improvements to regional interstates or major arterials that could be used as alternate routes during construction. Currently, improvements are planned along primary east-west routes, including North Avenue (IL 64) and Cermak Road (Figure 3-136), as well as capacity improvements along I-55. Spot improvements may also be implemented along Madison Street and Roosevelt Road.
- Improvements that would maintain existing I-290 mainline characteristics, such as number of through lanes and existing vertical clearances. Advance work would maintain a minimum six-lane mainline section, with temporary off-peak/night-time single-lane closures.

Figure 3-136. Primary Off-System Improvements

- Projects that would help accelerate the overall project schedule in reducing the duration of mainline impacts by eliminating major constraints to mainline reconstruction.
- Projects that would provide specific limited improvements as part of the overall project, but would generally not be dependent on completion of other project elements.

Local Cross-Road and Rail Bridge Reconstruction

Where feasible, identified local crossings of I-290 would be constructed and improved in advance of mainline construction. This is intended to deliver early community-related project benefits and to reduce the impacts to local connectivity during the mainline construction phase. The CTA, CSX, and IHB railroad bridges, which require complex staging and construction techniques, would also need to be constructed in advance of any mainline construction to minimize the overall duration of mainline construction. As part of the I-290 reconstruction, the existing CTA bridge over I-290 is planned to be relocated approximately 65 feet to the east to maintain rail traffic.

Existing cross-road structures over I-290 that could feasibly be advanced ahead of the mainline reconstruction include DesPlaines Avenue; Circle Avenue; Oak Park Avenue; East Avenue; Ridgeland Avenue; Lombard Avenue; Laramie Avenue; and Cicero Avenue. The feasibility is based on vertical clearance requirements, pier location, and maintaining the existing number of expressway lanes open during bridge reconstruction. The bridge improvements would require some localized mainline lane

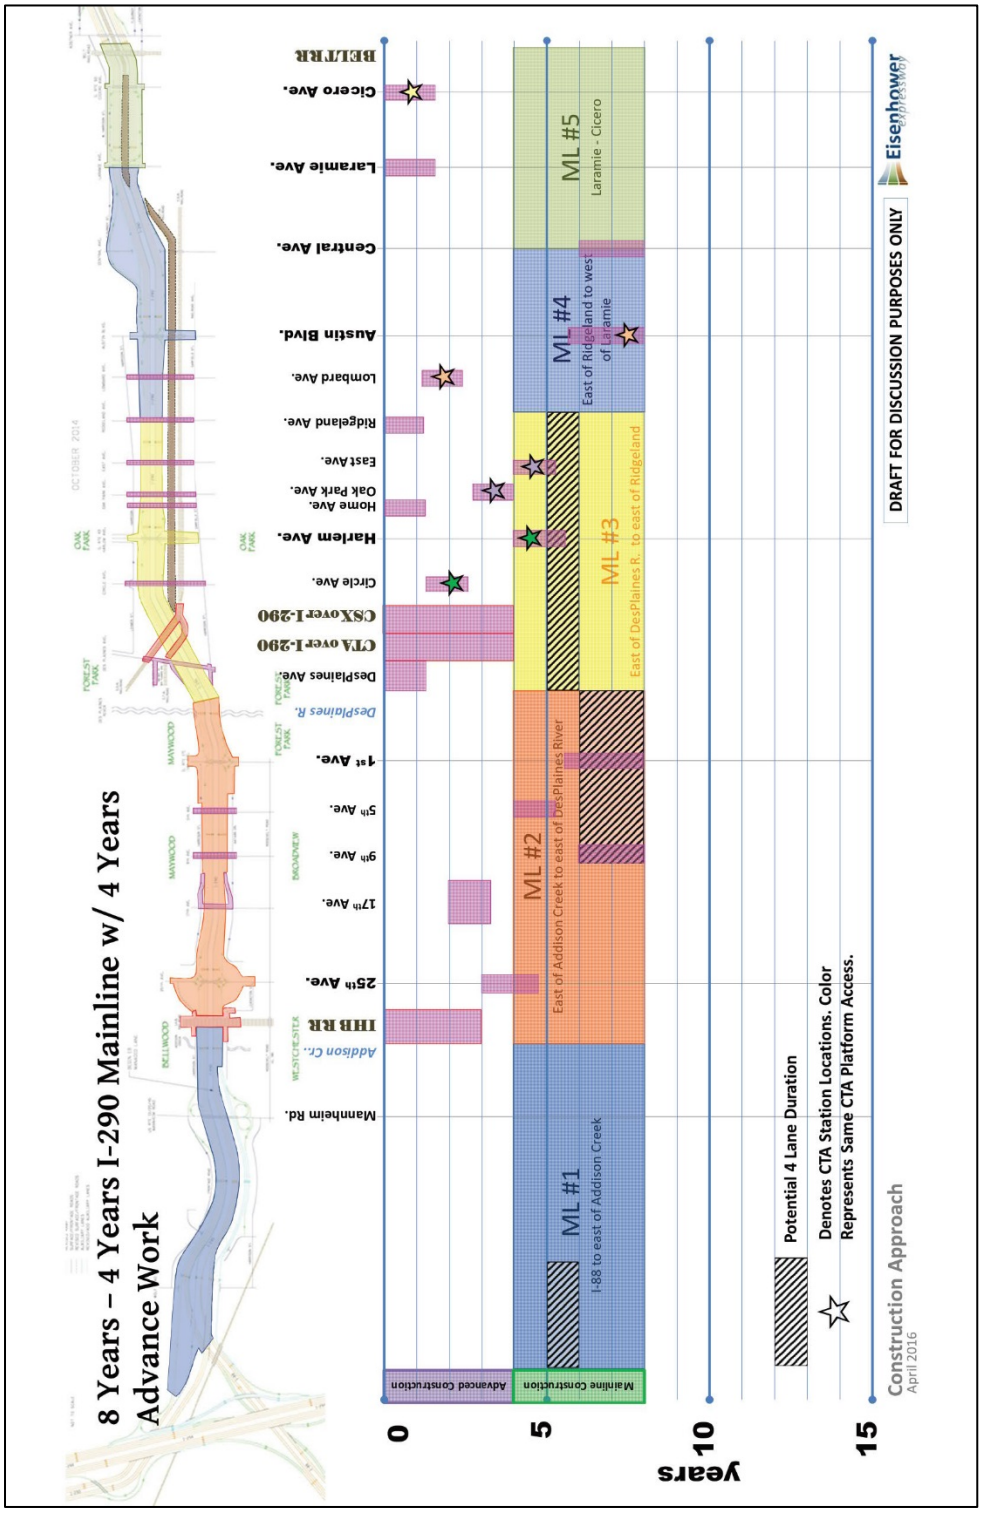
shifts during bridge reconstruction; however, the existing number of mainline lanes is expected to be maintained throughout.

The IHB railroad bridge over I-290 needs to be lengthened to accommodate the additional mainline lanes and the proposed 25th Avenue ramp improvements. This is a very heavily used railroad bridge; three out of the four tracks are required to remain in service at all times during construction, which results in an extended construction period. Constructing this bridge in advance of mainline construction is required, but it would also expedite mainline reconstruction.

The CTA and CSX bridges over I-290 represent a primary constraint and challenge to mainline reconstruction. Due to the complexity of the structural framing and interface between the structures, these two bridges together hold the highest construction schedule risk. Because of the way these bridges interface with I-290 and the proposed improvements, the simultaneous reconstruction of these bridges prior to mainline construction would facilitate mainline reconstruction by minimizing complex mainline road construction staging. The design and construction sequencing of railroad structures would require final approval from CTA and CSX, as appropriate.

Off-System Arterial Improvements

Off-system local arterial improvements are being evaluated to improve mobility along parallel routes adjacent to the Project Corridor both during construction and long term. As most of the arterial corridors within the Study Area are already built-out and currently at or near capacity, opportunities for physical improvements are limited; therefore, appropriate strategies for improved mobility largely center on using the existing roadway network more efficiently with relatively low-cost investments in signal system and Intelligent Transportation System (ITS) technologies (smart technologies). Physical improvements, such as resurfacing to address pavement smoothness and ADA ramps for accessibility, would also be addressed on the off-system arterial roads. Primary east-west routes being evaluated for advance work are North Avenue and Cermak Road, with more limited improvements to be considered on Madison Street and Roosevelt Road.



I-55 Express Toll Lanes

As part of a separate study completed in July 2016, IDOT is planning the addition of Express Toll Lanes (ETL) along I-55. To help address construction-related mobility issues from a regional perspective, IDOT is looking to implement the I-55 proposed capacity improvements in advance of the I-290 mainline reconstruction, which would provide a regional alternative to I-290.

3.14.1.2 I-290 Construction Staging

This section outlines the approach and assumptions of the I-290 construction. The overall construction is anticipated to occur over 8 years, with 4 years of advance work and 4 years of mainline construction (Figure 3-137). Construction staging would require periods of mainline lane reductions from three to two lanes in each direction. For planning purposes, the proposed mainline construction packaging is subdivided into five mainline contracts based on the potential to be constructed individually.

Figure 3-137. Construction Staging

Source: WSP Parsons Brinckerhoff, 2015.

Mainline Construction Assumptions

Current proposed mainline and cross-road designs and available information regarding existing conditions were used in establishing the construction assumptions. The following advance work assumptions should be reviewed and discussed during future stakeholder and IDOT meetings, and further investigated during final design (Phase II).

- There would be discrete areas where the available work space would only allow two eastbound and two westbound mainline work zone travel lanes (i.e., a temporary four-lane mainline section). Known areas requiring two lanes are: 1) at the I-290 westbound/eastbound western split; 2) from 1st Avenue to the Des Plaines River bridge; and 3) between the DesPlaines Avenue and Ridgeland Avenue bridges. Other sections of two-lane traffic per direction may be needed as the design advances.
- Full mainline closures would be required for short durations (overnight or weekend) where safety warrants it, such as setting or removing girders over traffic.
- For extended sections of the corridor, contractors may utilize up to one additional work zone travel lane in each direction during evening/off-peak hours using movable "zipper" barriers (maintaining a minimum of one lane in each direction with IDOT approval).
- The proposed maintenance of traffic design speed on I-290 would be reduced to 45 mph, which is 10 mph below posted speed.
- It is permissible to proceed with partial closures and/or detour routes at the west end of the corridor at the I-88/I-290 junction, including reduction of the I-88 westbound ramp from two lanes to one lane and fully detouring I-88 eastbound onto the collector-distributor road ramp.
- Temporary pavement, retaining walls, and bridge structures would be required for mainline construction. The temporary items are needed to ensure providing a minimum two lanes open in each direction on I-290 and providing contractor staging and working areas throughout the corridor.
- Closures of two consecutive interchange points, such as 25th Avenue-1st Avenue, 17th Avenue-9th Avenue, Harlem Avenue-Austin Boulevard, and Central Avenue/Laramie and Cicero Avenue, would be avoided.
- Closures of two consecutive cross-roads would be avoided.
- No full closures of Blue Line stations for mainline construction (leave at least one station access per platform open during construction).

Proposed structural improvements would utilize existing bridge substructure elements and retaining walls where existing elements are coincident or substantially coincident with proposed substructure elements. This assumption would be validated in the future with additional structural analysis and construction plans (Phase II), which are not yet completed for the project.

Access to properties along the arterial and local streets within the project limits would be maintained by staged construction phasing, temporary access roads, or other appropriate means. Local traffic may be stopped for short periods, temporarily inconveniencing motorists and businesses while construction equipment is moved.

Communication Plan

During the project design phase, IDOT will develop additional guidelines for preparation of a project-specific communication plan. Prepared as a special provision during Phase II Design, a plan will be used as a method for notifying local communities about construction activities and offer opportunities for stakeholder feedback. The guidelines will include development of notification procedures regarding regional air quality, local construction activities, and emergency situations should they arise. Guidelines for communication will also address everyday occurrences and potential exposures to routine construction dust. This will include coordination with local stakeholders and agencies to develop outreach techniques with respect to minimizing and/or preventing construction dust exposure adjacent to the corridor.

The plan will include public and agency coordination to communicate the sequence of work in each community, mitigation strategies to address construction effects, coordination with the local emergency services, schools, and other community services to identify and address any route and emergency vehicles access concerns during construction. The discussion of the roadways under local jurisdiction that could be utilized for construction access would continue during Phase II Design and Phase III construction.

During the construction phase, public involvement would continue with establishing a local point of contact and an IDOT contact in each community, weekly contractor meetings to discuss work to date and upcoming work, a project hotline, and project updates communicated via a project website, social media, and other means. Special signage may be required to alert the public of changes in access and other construction-related traffic pattern changes.

3.14.2 Water Resources

Construction typically associated with bridges, culverts, and roadway approaches would involve grading, filling, and excavation. These activities increase the erosion potential by the reduction in vegetative cover resulting from soil disturbance by heavy equipment. Placement of structures in streams may increase turbidity (suspended solids) and sedimentation and temporarily alter downstream hydraulics and substrate conditions.

Increased sedimentation during construction could cover natural substrate, thereby affecting habitat for some species of fish, mussels, and macroinvertebrates. The degree of impact would vary based on site-specific conditions, such as the type of crossing structure, stream substrate, stream depth, and stream velocity. To help reduce the release of sediment into the study area streams during construction, the IDOT BDE Manual, Chapter 59, Landscape Design and Erosion Control, would be implemented.

Compliance with Section 280 of the IDOT Standard Specifications for Road and Bridge Construction, adopted January 1, 2007, would also be met. Soil erosion and sediment control measures would be installed in areas of active construction, in particular, near stream crossings, wetlands/WOUS, and drainage ways. Disturbance of streamside vegetation would be kept to a minimum. To minimize soil loss and subsequent sedimentation, an erosion and sediment control plan would be prepared as part of the contract documents. Areas of special concern, where erosion and sediment control would be needed, would be identified during subsequent studies.

The proposed project would be subject to the requirements of IEPA's NPDES permit for construction site stormwater discharges. NPDES permit coverage is required when a construction project disturbs 1 acre or more of total land area, or is part of a larger common plan of development that ultimately disturbs 1 or more acres of total land area. See Section 3.18, Permits and Approvals, for further information.

As required by the NPDES permit, a stormwater pollution prevention plan (SWPPP) would be prepared that identifies soil erosion and sediment control practices to be used throughout the construction process to reduce the discharge of pollutants to receiving waters. Appropriate soil erosion and sediment controls would be implemented onsite and be modified to reflect the current phase of construction. All temporary erosion and sediment control measures would be inspected, maintained, and repaired/replaced, as necessary, to maintain NPDES compliance. The following is a list of BMPs that could be used to improve water quality, reduce soil erosion, and limit the amount of dust created in association with construction activities for the project:

- Storm drain inlet protection;
- Stone aprons at flared end sections;
- Stabilized construction entrances;
- Temporary stabilization (mulching, seeding);
- Rolled erosion control products (erosion control blankets or mats);
- Permanent seeding;
- Silt fence barrier;
- Temporary ditch checks;
- Sedimentation basins;
- Diversion dikes/channels; and
- Preservation of existing vegetation.

3.14.3 Air Quality

Demolition and construction can result in short-term increases in fugitive dust and equipment-related particulate emissions in and around the Study Area. Air quality impacts would be short term, occurring only while demolition and construction are in progress and local conditions are appropriate. Fugitive dust emissions typically are

associated with building demolition, ground clearing, site preparation, grading, stockpiling of materials, onsite movement of equipment, and transport of materials. The potential is greatest during dry periods, periods of intense construction activity, and high wind conditions. IDOT's Standard Specifications for Road and Bridge Construction, Article 107.36, includes provisions on dust control. Under these provisions, dust and airborne dirt generated by construction work would be controlled through dust control procedures or a specific dust control plan. During the project design phase, IDOT will develop an additional special provision to include a project-specific dust control plan. The plan will augment existing dust control methods currently in place in IDOT standard specifications. The plan will identify methods to reduce or contain construction dust that the contractor will employ during construction activities to further reduce fugitive dust in urban environments. These may include best practices from other similarly sized and located projects that may be applicable during the development of Phase II documents.

During construction, the contractor and IDOT will meet to review the nature and extent of dust-generating activities and would cooperatively develop specific types of control techniques appropriate to the specific situation. Techniques that may warrant consideration include minimizing track-out of soil onto nearby publicly traveled roads, reducing speed on unpaved roads, and covering haul vehicles. Blowing dust from areas cleared or excavated for access or construction purposes can be minimized by applying water to unpaved areas. The effectiveness of watering for fugitive dust control depends on the frequency of application. Street cleaning would also be used to control dust, as necessary. Paved areas that have soil on them from the construction site would be cleaned as needed, using a street sweeper or some alternative method.

These and other construction-related air quality best control practices identified by USEPA and other agencies will be developed during Phase II Design as part of a construction air quality special provision. The provision is intended to improve contractor awareness of best practices that could be used during construction including diesel emission reduction strategies, such as idling restrictions, diesel engine retrofits for construction equipment, and using clean fuels (ultra-low sulfur diesel, emulsified diesel, compressed natural gas). IDOT currently requires diesel emission reduction and clean fuel provisions for all construction contracts in Cook County.[55] Equipment-related particulate emissions could also be reduced if construction equipment is well maintained. With the application of appropriate measures to limit emissions during construction, the project would not cause significant, short-term PM air quality impacts.

3.14.4 Construction Noise and Vibration

Trucks and machinery used for construction produce noise that may affect some land uses and activities during the construction period. Individuals inhabiting the homes along the proposed improvements would, at some time, experience perceptible construction noise from implementation of the proposed project. To minimize or

[55] IDOT BDE Special Provision for Construction Air Quality – Diesel Retrofit; Section 107.41 (a) and (b) of IDOT Supplemental Specifications and Recurring Special Provisions.

eliminate the effect of construction noise on receptors, mitigation measures have been incorporated into IDOT's Standard Specifications for Road and Bridge Construction, Article 107.35.32.

Construction of the proposed project could result in temporary noise and vibration increases within and adjacent to the Study Area. The noise and vibration would be generated primarily from trucks and heavy machinery used during construction and demolition. Any anticipated noise and vibration impacts likely would be confined to normal working hours, periods generally considered to be tolerant of noise and vibration. No adverse noise and vibration impacts are expected during construction, and construction methods that minimize the potential for noise and vibration impacts, as well as monitoring of sensitive structures during construction, would be specified as needed in subsequent project phases.

IDOT will implement a structure monitoring program that will begin prior to construction. Existing conditions of buildings adjacent to or near the expressway (as identified in coordination with the local communities) will be documented prior to any project-related construction activity. IDOT will work with the communities to develop a vibration and displacement control plan to identify items of work for structure monitoring during construction.

3.14.5 Solid Waste

The contractor would dispose of grass, shrubs, trees, old pavement, miscellaneous debris, and other solid wastes generated during demolition and construction in accordance with state and federal regulations, as necessary. Waste disposal would follow IDOT's Standard Specifications for Road and Bridge Construction, Article 202.03. Nonhazardous and uncontaminated construction and demolition debris would be salvaged to the extent practical. Solid waste, including trash, construction debris, and other items, would be collected and disposed of offsite by the contractor. The contractor would be responsible for acquiring the permit required for such disposal. Onsite burning would not be permitted. No solid materials, including building materials, would be discharged to surface waters, except as authorized (e.g., IEPA). All waste would be collected and stored in approved receptacles. Liquid wastes would not be deposited into dumpsters or other containers that may leak. Receptacles with deficiencies would be replaced as soon as possible, and appropriate cleanup would take place if necessary. Construction debris would not be buried onsite. Waste disposal would comply with all local, state, and federal regulations. Proposed borrow areas, use areas (e.g., temporary access roads, staging/storage areas), and waste areas would follow IDOT's Standard Specifications for Road and Bridge Construction, Article 107.22.

Onsite special waste storage, including hazardous waste, would be minimized and would employ labeled, separate special/hazardous waste containers. Nonhazardous waste would be segregated and handled separately. Special and hazardous wastes would be disposed of in the manner specified by local, state, and federal regulations.

Concrete waste or washout would not be allowed to reach a stormwater drainage system or watercourse. Concrete washout would be contained and completed in a designated location. Washout containment facilities would be of sufficient volume to contain all liquid and concrete waste materials, including enough capacity for anticipated levels of rainwater.

3.14.6 Utility Services

Construction work would be coordinated with public utilities to avoid conflicts and minimize planned interruptions of service. When service interruptions are unavoidable, every effort would be made to limit their duration, and every effort would be made to give the public lengthy fair warning of any planned occurrence of service interruption.

3.14.7 Energy

Construction of the proposed improvement would require indirect consumption of energy for processing materials, construction activities, and maintenance for the lane miles to be added within the project limits. Energy consumption by vehicles in the area may increase during construction due to possible traffic delays. The number of improvements and the time required to complete them would have a corresponding effect on the fossil fuels consumed; however, in the long term, post-construction operational energy requirements would offset construction and maintenance energy requirements and result in a net savings in energy usage.

3.14.8 Parks and Recreational Facilities

It is expected that access to all recreational facilities would remain throughout construction. For those facilities immediately adjacent to the construction area, there would likely be an increase in noise and vibration during the hours of construction activity. In addition, these facilities may experience a temporary increase in fugitive airborne dust and a temporary change to the existing visual setting in those areas immediately adjacent to the construction activity. Prior to and during construction, there would be coordination with the OWJ of these facilities to minimize the extent of potential construction-related impacts.

3.15 Indirect and Cumulative Impacts

There have been no substantive changes to this section since publication of the DEIS.

3.15.1 Approach

This section evaluates the potential for indirect and cumulative impacts. Potential indirect and cumulative impacts are defined as follows:

- Indirect effects are "caused by an action and are later in time or further removed in distance but are still reasonable foreseeable" (40 CFR 1508.8).
- Cumulative effects "result from the incremental consequences of an action when added to other past and reasonably foreseeable future actions" (40 CFR 1508.7).

The basis for this analysis is the recognition that while a project has various direct impacts on social and environmental resources, it may also have indirect and cumulative impacts. The analysis of indirect impacts considers the effects of the build alternatives, whereas the analysis of cumulative impacts considers the effects of other past, present, and reasonably foreseeable future actions.

A review of the project-related impacts concluded that the resource analyses for indirect and cumulative impacts are similar to one another. The period for both analyses extends through 2040. The same resources are discussed for indirect and cumulative impacts, including effects on regional growth and development patterns, as well as water quality, wetlands, and biological resources. The geographic extent of these analyses varies with the resource. Socio-economic effects would be local (Project Corridor) and regional. Water resources are evaluated in the context of the Study Area and relevant watersheds, and wetlands and biological resources are analyzed in terms of local and regional value.

Indirect and cumulative effects would not be expected to occur with the No Build Alternative because the project would not be constructed.

3.15.2 Indirect Impacts

This section evaluates the potential for indirect effects to resources in the Study Area.

3.15.2.1 Socio-economic Effects

The indirect socio-economic effects were evaluated by developing year 2040 socio-economic forecasts as part of the I-290 Study. Socio-economic forecasts, including population and employment forecasts, are used as input to the I-290 travel forecasting model to estimate future highway and transit travel for use in design, environmental, and financial analyses. The year 2040 was selected as the planning horizon and design year for consistency with the MPO's MTP. This portion of the metropolitan Chicago region has established stable residential areas and a solid employment base. It is expected that the Project Corridor would continue to maintain its competitive position and serve an important role in the larger Chicago economy in terms of housing and jobs.

The 2040 population and employment forecasts developed by CMAP staff for their GO TO 2040 Comprehensive Regional Plan were a departure from previous forecasting practices in the region. Prior to the GO TO 2040 Plan, the socio-economic forecasting practice in northeastern Illinois was based on municipal and county consultation, historic trends, local land use policies, local development proposals, available land for development, and regional and county level control totals in a "market-based" approach. This prior socio-economic and land use methodology and forecast was adopted as the planning baseline for the region and used for major project development and for the MTP.

In reviewing the CMAP population and employment forecasts for use in the I-290 Study, IDOT concluded that the strict policy-based forecast developed by CMAP staff was not appropriate for evaluating specific transportation facilities because the forecasts:

- Are aspirational in nature, resulting in a "policy-based plan (dealing with the investments and high-level choices that shape our region) as opposed to a land use plan (dealing with specific types of development in specific locations)."[56]
- Do not directly address population and employment differences between No Build and build scenarios as CMAP staff's policy-based forecasts, which reflect the desired development for the region, would be the same regardless of which major transportation projects were included in the plan.
- Assume the recommended policies in the GO TO 2040 Comprehensive Regional Plan will be instituted by 2040 to achieve the policy-based forecast. CMAP recognizes that implementation of its vision relies on a multitude of decisions made at different levels of local, state, and federal government. CMAP does not have authority to implement land use plans. The authority over local land use resides with local governments.

IDOT determined that a refined market-based forecast, similar to the type of forecasts historically prepared by CMAP, was required to provide the most appropriate traffic forecasts for use in the design, environmental analysis, and potential toll revenue forecasting for transportation improvements for the Study Area. In addition, with the potential for tolling options for the project, any potential toll and revenue evaluations needed to finance a project would require investment-grade forecasts. Lenders and bonding agencies are typically reluctant to assume that goal-based, policy-driven recommendations would be entirely effective in the face of *laissez-faire* market economics. The Illinois Tollway has developed a similar market-based socio-economic forecast approach for use in their toll revenue studies.

CMAP staff anticipated the need for alternative socio-economic forecasts for project-specific studies and issued guidelines for preparing these alternative forecasts.[57] The I-290 project team adhered to these CMAP staff guidelines and coordinated with them in developing the market-driven socio-economic forecasts used for this project.

---

[56] CMAP GO TO 2040 Comprehensive Regional Plan, October 2010, page 26.

[57] CMAP Forecast Principles for Data Users and Forecast Developers," CMAP, April 2011.

The methodology employed to develop the I-290 No Build and Build socio-economic forecasts is described in Appendix B-2. This methodology recognizes the important interrelationships between transportation systems and urban development (i.e., accessibility influences locational decisions which, in turn, influence accessibility). In selecting a location for an activity (e.g., industrial plant, office building, residence) the decision maker considers the accessibility of the various potential sites to concentrations of various activities (e.g., labor force, job concentrations, schools, recreational activities). This is general knowledge to market analysts, real estate brokers, and developers, and it is used in conducting their day-to-day business. It also is understood that improving the access of developable or redevelopable sites increases the development potential of those sites, attracting development (i.e., residential, commercial/industrial, institutional) that may have occurred elsewhere in the region.

The I-290 project team developed 2040 No Build market-driven socio-economic forecasts assuming no I-290 Eisenhower Expressway improvements (no additional lanes on I-290) and no HCT extension to the west from the CTA Blue Line Forest Park Station (no Blue Line Forest Park Branch extension). The 2040 No Build socio-economic forecasts do assume implementation of other major capital transportation projects outside of the Study Area that are included in the approved, fiscally constrained, MTP and TIP for the region.

The 2040 Build socio-economic forecasts were also developed for use in testing the I-290 Round 3 DEIS build alternatives. The I-290 Build socio-economic forecasts assumed implementation of an additional lane (in the form of a managed lane) on I-290, and an HCT extension (such as a Blue Line extension to Mannheim Road from the CTA Blue Line Forest Park Station), as well as other major capital transportation projects currently in the fiscally constrained long-range transportation plan and TIP.

Build and No Build Population and Employment Differences

The differences between the I-290 2040 Build and No Build population and employment forecasts are depicted in the following figures. The transportation improvements included in the I-290 build alternatives result in changes to accessibility of the region, which then affect population and employment forecasts. The improvement of access to developable or redevelopable sites increases the development potential of those sites, attracting development (i.e., residential, commercial/industrial, institutional) that may have occurred elsewhere in the region. Because the I-290 build alternatives include highway and transit improvements, composite accessibility effects were used to measure changes in accessibility for the build alternatives.

Figure 3-138 and Figure 3-139 show the impact of the Highway Component of the I-290 build alternatives on the redistribution of 2010-2040 population and employment growth, while Figure 3-140 and Figure 3-141 show the impact of the Transit Component of the I-290 build alternatives. These figures show that the Highway Component of the I-290 build scenario has a greater impact on population and employment growth than the Transit Component of the build scenario due to the greater improvement in accessibility from the highway improvements.

Figure 3-138. Change in Population – Build vs. No Build Due to Highway Improvements

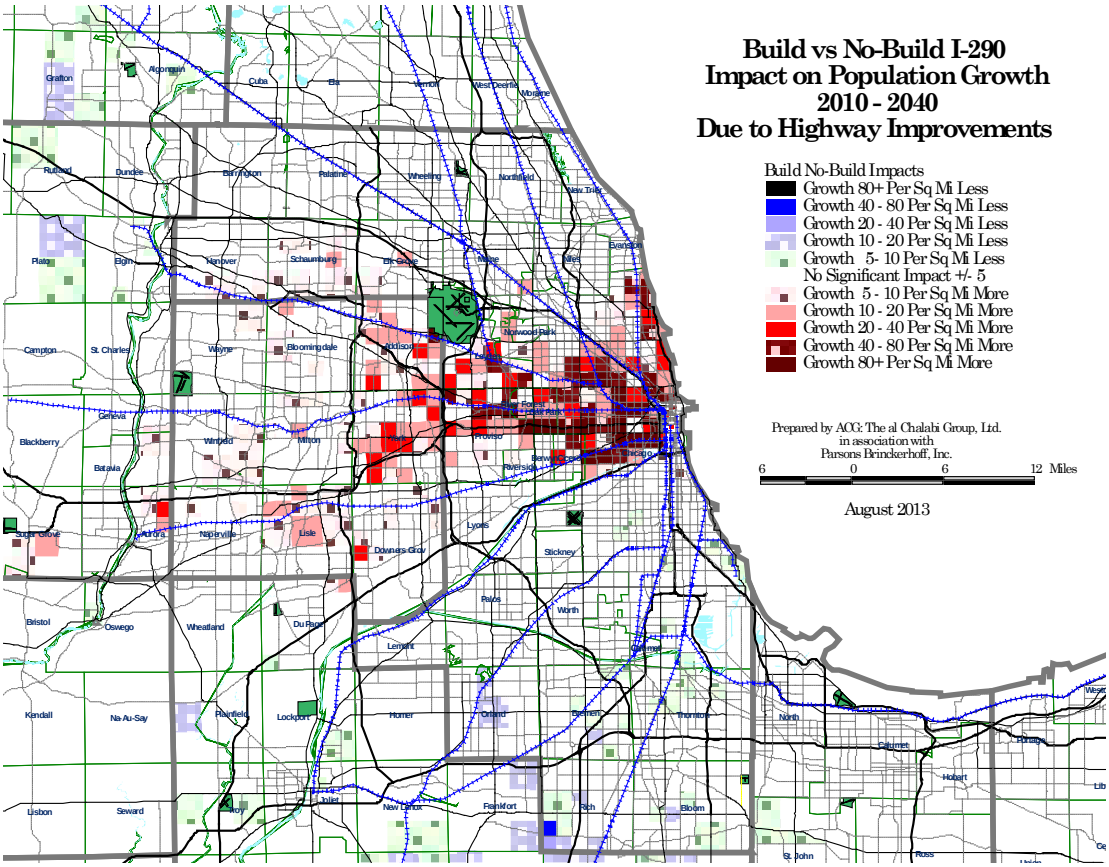


Figure 3-139. Change in Employment – Build vs. No Build Due to Highway Improvements

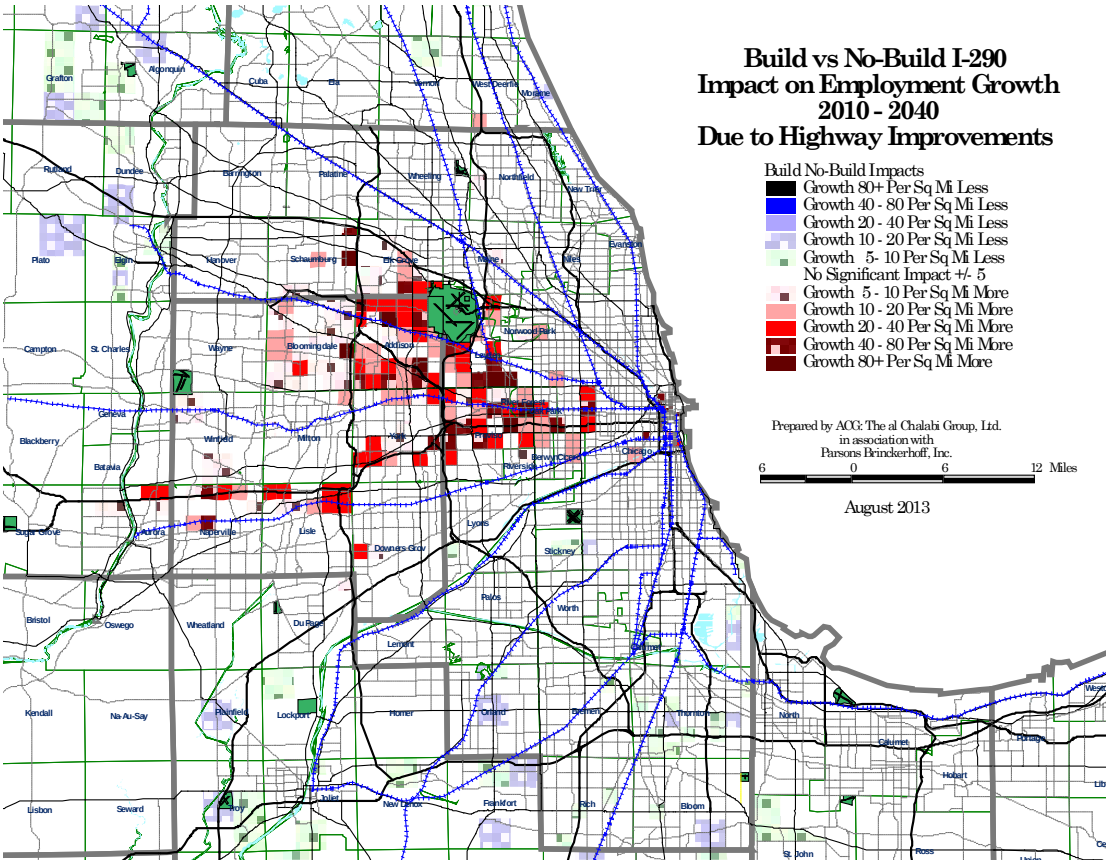

Figure 3-140. Change in Population – Build vs. No Build Due to Transit Improvements

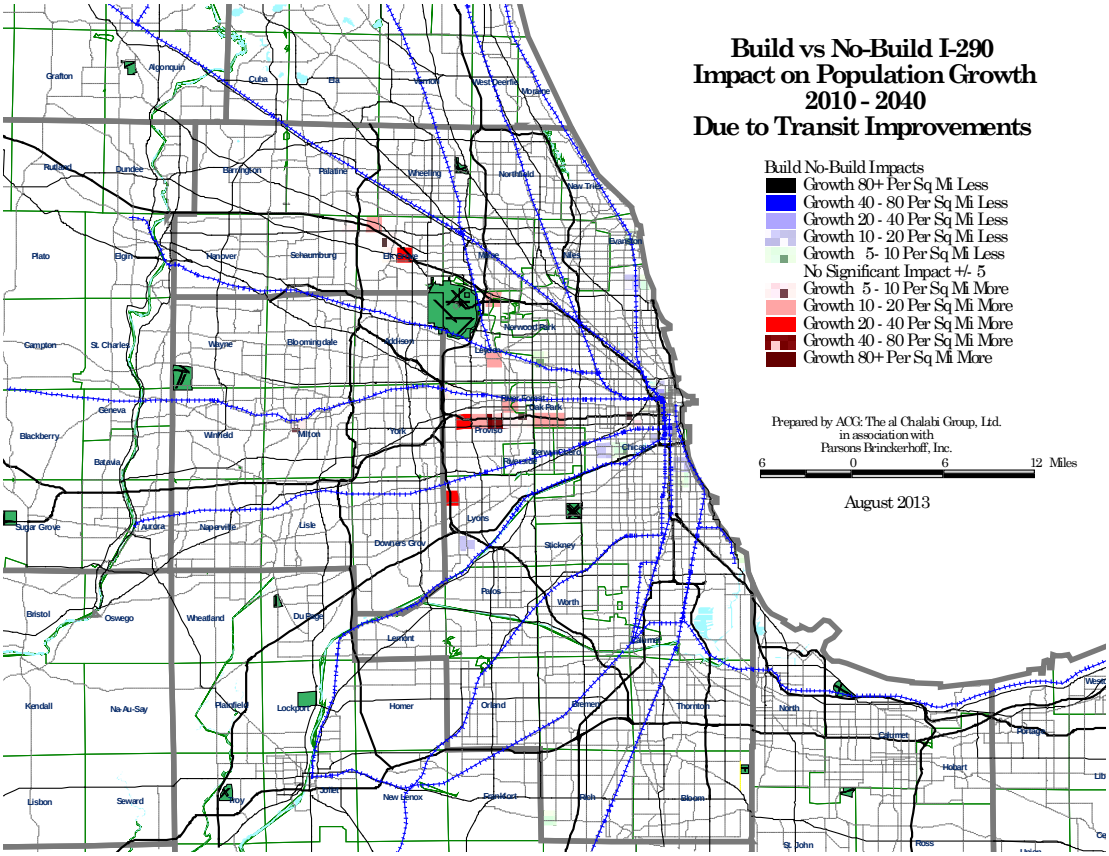

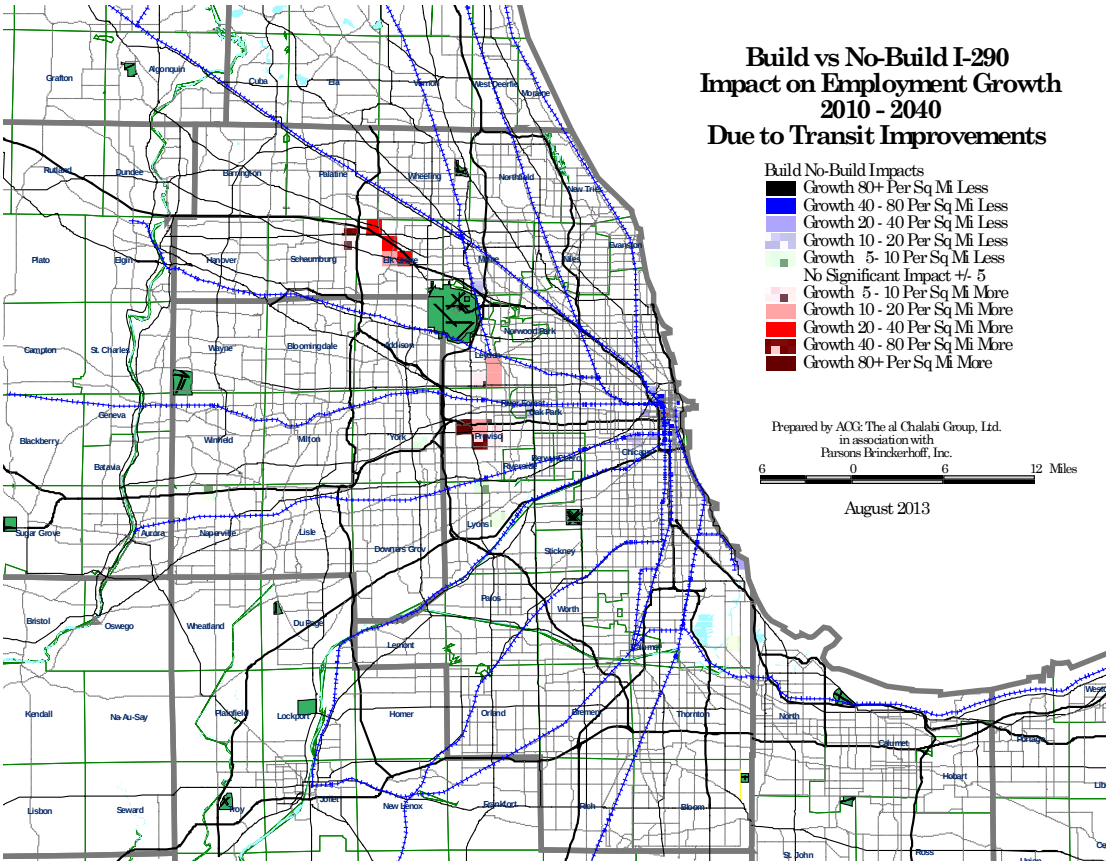

Figure 3-141. Change in Employment – Build vs. No Build Due to Transit Improvements

A comparison of the resulting I-290 Study Area 2040 population and employment forecasts is shown in Table 3-52. As seen in this table, the I-290 Study Area population and employment forecasts for the No Build versus build scenario indicate a less than 1 percent change. This is due to the existing built-out urban conditions in the Study Area and that the I-290 project reflects improvements to an existing facility that already provides accessibility to the Study Area.

Table 3-52. Comparison of I-290 Study Area 2040 No Build and Build Forecasts

Forecast	2040 No Build	2040 Build	Change
Population	649,215	651,912	0.4%
Employment	309,334	310,967	0.5%

Given the minor differences in population and employment forecasts between the No Build and build scenarios, it was determined that a single build scenario could be used in the I-290 travel forecasting model for the four DEIS build alternatives. Because the DEIS build alternatives include very similar physical transportation improvements, with the primary difference among them being operational (e.g., how the fourth lane is managed and if there is tolling), overall accessibility is expected to be similar between the build alternatives. The HOV 2+ Alternative was selected to develop the highway and transit travel times for use in determining the composite accessibility of the 2040 build scenario, because it represented a middle ground in operational control in terms of lane management strategies.

In addition to the analysis on population and employment described above, construction of the project would indirectly affect the area economy to the roadway construction sector by increasing demand for locally produced materials needed for construction, such as concrete, wholesale and retail trade items, rebar, and other construction materials. This would affect suppliers of those products. Other sectors of the economy would be benefited by employees hired in the construction industry who may increase their expenditures in restaurants, grocery stores, etc.

The indirect impacts to Project Corridor communities, including environmental justice communities, are described in Sections 3.15.2.2 through 3.15.2.13 below. Since most of the Study Area includes low-income or minority populations, the indirect impacts described in the following subsections would affect these groups.

3.15.2.2 Cultural Resources

Indirect effects on cultural resources would be largely those that may result from additional development within and beyond the Study Area. Development within the vicinity of the proposed project would continue under existing developmental review regulations of the Project Corridor communities, which would allow a continuation of status quo development of the area.

3.15.2.3 Air Quality

An air quality analysis was performed using projected traffic volumes that incorporate anticipated traffic generation from planned development in the Study Area for the future years under the build alternatives and the No Build Alternative; therefore, the regional burden air quality analysis takes into account the indirect effects of the project and other traffic growth that would be associated with the proposed project.

A full air quality discussion is included in Section 3.3, Air Quality, and a short summary is listed below:

- The GP Lane Alternative shows a slight increase in all regional criteria pollutants except for PM_{10}, for which it shows a slight decrease, compared to the No Build Alternative;
- The HOV 2+, HOT 3+, and HOT 3+ & TOLL Alternatives show a slight decrease in all regional criteria pollutants compared to the No Build Alternative; and
- All changes in regional pollutant burdens are minimal, with all pollutants showing less than a 1 percent change when comparing the build alternatives to the No Build Alternative in 2040.

3.15.2.4 Noise

Noise impacts are expected to be direct and not result in indirect impacts. See Section 3.4, Traffic Noise, for a full discussion on the direct noise impacts.

3.15.2.5 Energy

During the construction period, there would be an indirect consumption of energy for general construction activities and processing of materials. Potential traffic delays occurring during the construction period may result in increased energy consumption by vehicles experiencing those delays. The overall consumption of fossil fuels consumed during the construction process would correlate to the amount of construction activity, types of activity, and time needed to complete the activity.

3.15.2.6 Natural Resources

There are no identified indirect effects to natural resources. See Section 3.6, Natural Resources, for a full discussion on direct impacts to natural resources.

3.15.2.7 Groundwater

Stormwater runoff from increased impervious surface could result in reduced groundwater recharge rates. Pollutants have the potential to adversely affect groundwater sources of water supply, although groundwater wells are only used as a backup source because drinking water comes from Lake Michigan. See Section 3.8, Groundwater, for a full discussion of potential direct impacts to groundwater.

3.15.2.8 Floodplains

There are no identified indirect effects to floodplains. See Section 3.9, Floodplains, for a full discussion on direct impacts to floodplains. During coordination with the communities in the Study Area, an opportunity was identified to manage localized flooding in the Village of Maywood with a new storm sewer trunk line along the I-290 north frontage road. This trunk line would outlet to the Des Plaines River.

3.15.2.9 Water Resources

Increased traffic and impervious surfaces would result from transportation infrastructure completed over the next 20-year period. Based on water quality modeling, this would result in additional pollutants being deposited on the roadway. During storms, these pollutants could be transported to receiving waters. Water quality standards would be maintained, minimizing any potential indirect adverse effects.

3.15.2.10 Wetlands

The Study Area is a highly developed area with few wetlands that can generally be attributed to urban development. As noted in Section 3.10, Wetlands, no wetlands were identified in the Project Corridor; therefore, there would be no indirect impacts to wetlands.

3.15.2.11 Special Waste

Indirect effects from hazardous waste and waste from normal operations of I-290 following construction of any of the build alternatives would primarily be associated with runoff of contaminants entrained in stormwater, including fuel, lubricants, heavy metal compounds from tires and brake pad dust, and automobile engine coolants such as ethylene glycol leaking from passing vehicles. Construction of the proposed project would improve traffic operations along the entire Project Corridor. This would ultimately help reduce the risk of accidents, including those involving hazardous materials, and would thereby decrease the amount of harmful materials that might enter soil and water resources in the Study Area. Remediation of known or potentially contaminated hazardous materials sites for the proposed project would potentially be an indirect benefit of the build alternatives. Removing these materials from the Study Area eliminates the potential health hazards and liability risks from these materials remaining in the area.

3.15.2.12 Special Lands

Construction of any of the build alternatives could potentially improve access to existing or future parks, recreation facilities, or special lands, but it is unlikely to have other effects beyond temporary minor increases in noise levels during construction.

3.15.2.13 Visual Resources

No indirect effects associated with visual quality were identified. See Section 3.13, Visual Resources, for a full discussion on direct impacts to visual resources in the Project Corridor.

3.15.3 Cumulative Impacts

This section describes the cumulative impacts associated with the proposed project. The analysis for the project considered the cumulative impacts on resources in the Study Area. This included the proposed project's direct and indirect impacts, as well as the impacts of other major federal, state, and private actions in the Study Area not related to the project. The projects considered to be "reasonably foreseeable actions" have typically received preliminary approvals, are included in local plans, or have already advanced in project development. The major federal and state transportation projects identified as other actions are described in full in CMAP's 2014 GO TO 2040 Comprehensive Regional Plan. The largest nearby project is the I-290 Jane Byrne (formerly Circle) Interchange Reconstruction Project, which is currently under construction near the eastern limits of the Study Area that would improve circulation between I-290 and I-90/I-94.

3.15.3.1 Socio-economic Effects

Cumulative impacts to existing socio-economic resources in the Study Area are limited due to the area's urban, largely developed character. Roadway and transit improvements in the regional plan can foster beneficial community results, such as improving accessibility and mobility and supporting future growth and planning policies. Cumulatively, the I-290 project represents a small incremental impact on socio-economic conditions in the context of the other identified actions occurring in the area that have or would have an effect on socio-economic conditions. Improved travel times in the Project Corridor for all of the build alternatives on I-290 may spur private redevelopment, and industrial and commercial land uses may recognize the intrinsic value and competitive advantage of better local and regional transportation access. Therefore, underused or underdeveloped properties in the area would be candidates for reinvestment.

Construction of the proposed I-290 project and other area projects would increase jobs in the region for the highway industry. The proposed I-290 project would not result in any adverse cumulative impacts on the regional economy. Additionally, the cumulative effects of these other area projects are not expected to substantially affect land use in the Study Area because the land uses are well established and consistent with local, county, and regional plans.

3.15.3.2 Cultural Resources

Neither the build alternatives nor the No Build Alternative for the proposed project are likely to cause adverse effects on cultural resources either within or beyond the limits of the project. Therefore, as the cumulative effects on cultural resources are anticipated to be minimal and are not likely to be different under either the build alternatives or No Build Alternative, additional analysis is not warranted.

3.15.3.3 Air Quality

An air quality analysis was performed using projected traffic volumes that incorporate anticipated traffic generation from planned development in the Study Area for the future years under the build alternatives and the No Build Alternative. Therefore, the air

quality analysis as documented in Section 3.3, Air Quality, takes into account the cumulative effects of the project and other traffic growth that would be associated with the proposed project. A short summary is listed below:

- The GP Lane Alternative shows a slight increase in all regional criteria pollutants, except for PM_{10}, for which it shows a slight decrease compared to the No Build Alternative;
- The HOV 2+, HOT 3+, and HOT 3+ & TOLL Alternatives show a slight decrease in all regional criteria pollutants compared to the No Build Alternative; and
- All changes in regional pollutant burdens are minimal, with all pollutants showing less than a 1 percent change, when comparing the build alternatives to the No Build Alternative in 2040.

3.15.3.4 Noise

The build alternatives would reduce noise adjacent to the roadway by constructing noise barriers at locations along the Project Corridor where they are reasonable and feasible to construct and where benefited receptors vote in favor of their construction (Section 3.4 for full details). While the build alternatives are not expected to have a cumulative effect on regional noise levels, the proposed project would result in a reduction of noise in the Study Area.

3.15.3.5 Energy

Construction and operation of the proposed project would consume energy. While consumptive energy losses would occur during construction of the proposed project, operation of the proposed project would not be measurably different from the No Build Alternative and thus would not materially contribute to the cumulative adverse effects to energy.

3.15.3.6 Natural Resources

Direct impacts to natural resources would be avoided or mitigated to the extent feasible, as described in Section 3.6, Natural Resources. Considered with the effects of past, present, and reasonably foreseeable future actions, the proposed project would have a negligible contribution to cumulative adverse effects on natural resources.

3.15.3.7 Groundwater

Direct groundwater impacts would be minimal and are described in Section 3.8, Groundwater. Considered with the effects of past, present, and reasonably foreseeable future actions, the proposed project would have a negligible contribution to cumulative adverse effects on groundwater.

3.15.3.8 Floodplain

Direct impacts to wetlands would be avoided or mitigated to the extent feasible. Considered with the effects of past, present, and reasonably foreseeable future actions,

the proposed project would have a negligible contribution to cumulative adverse effects on floodplains.

3.15.3.9 Water Resources

Increased traffic and impervious surfaces would result from recently completed transportation infrastructure over the next 20-year period, which could result in additional pollutants being deposited on the roadway. BMPs implemented consistent with federal, state, and local regulation are anticipated to minimize adverse consequences to water resources in the Study Area.

3.15.3.10 Wetlands

As discussed in Section 3.10, Wetlands, no direct impacts to wetlands are associated with this proposed project; therefore, as the cumulative effects on wetlands are not likely to be different under the build alternatives, additional analysis is not warranted.

3.15.3.11 Special Waste

The long-term cumulative effect of the build alternatives combined with the other projects in the Study Area represent a slight increase in the risk of accidental hazardous materials spills as a result of increased traffic volumes. These potential hazardous materials spills could lead to added stormwater pollution if such spills are not contained or materials not disposed in accordance with established procedures.

3.15.3.12 Special Lands

Neither the No Build Alternative nor the build alternatives for the proposed project are likely to cause effects on special lands, including parks and recreation resources, within or beyond the limits of the proposed project. Therefore, as cumulative effects on parks and recreation resources are anticipated to be minimal and are not likely to be different under the build alternatives, additional analysis is not warranted.

3.15.3.13 Visual Resources

The build alternatives would contribute to the visual change associated with past, present, and reasonably foreseeable future actions. Construction and operation of the proposed project would change the visual character by adding noise walls in many locations. There may also be areas where mature vegetation would be replaced with noise walls in the Project Corridor. The change in the design of the interchanges and ramps would also alter the visual character of the Project Corridor. The cumulative effects of such change are not expected to substantially alter the predominantly urban character of the Study Area.

3.16 Short-Term Use and Long-Term Productivity

There have been no substantive changes to this section since publication of the DEIS.

Short-term uses of the human and natural environment resulting from the proposed project would generally be those construction activities associated with the project. Construction of the proposed project would involve the short-term use of resources such as labor and land for construction staging and storage of materials. As with any major construction activity, temporary disturbances to the human and natural environments are expected to occur. Such temporary disturbances would include construction noise, vibration, visual impacts, temporary disruption of local traffic, and disruption to business and residential access within construction areas, and disturbance of vegetation, water resources, and wildlife habitat.

The negative short-term effects described above are offset by the long-term positive effects of the proposed project. The long-term outcomes of the proposed project would include improved safety and improvements to existing I-290 facility deficiencies. The long-term benefits of the proposed project, which include improved mobility for regional and local travel, access to employment, and improved modal connections and opportunities in the Study Area, require a certain necessary amount of short-term resource use. The long-term benefits of the proposed project, however, outweigh the short-term negative aspects associated with construction.

The proposed project would contribute to the maintenance and enhancement of long-term productivity for the communities in the Study Area by providing improved local and regional accessibility and improved safety for all transportation modes in the Study Area.

3.17 Irreversible and Irretrievable Commitment of Resources

There have been no substantive changes to this section since publication of the DEIS.

This section will discuss irreversible and irretrievable commitments of resources. A commitment of resources is irreversible when its primary or secondary impacts limit the future option for a resource. An irretrievable commitment refers to the use or consumption of resources that is neither renewable nor recoverable for later use by future generations.

Construction of the build alternatives along the Project Corridor would involve an irreversible commitment of many irretrievable resources. These resources include land, natural resources, resources used for construction materials and energy, and manpower.

Land used in construction of the proposed project is considered an irretrievable resource, along with everything below the surface. No areas of land within the proposed construction limits are currently open or in a natural state, so no impacts are expected.

Large amounts of other natural resources, such as limestone, clay, asphalt (bitumens), gravel, sand, and iron ore, would be required for use in construction materials. Fabrication of construction materials and operation of construction vehicles and machinery would require energy derived from fossil fuels, in addition to other potential energy sources such as solar and electricity. Similar to mineral resources, fossil fuels are an irretrievable resource, the extraction and use of which is unrecoverable and irreversible; however, it is unlikely that their limited use in this proposed project would adversely affect the future availability of these resources.

Additionally, large amounts of labor are used in the fabrication and preparation of construction materials. While the labor specifically dedicated to the proposed project would be irreversible and irretrievable for other uses, the existing labor pool or new labor sources would be likely available if there are willing individuals.

Resources in the Study Area that are in the category of irretrievable resources include sand, gravel, and limestone. These resources are generally viewed as income-producing commodities. Extraction and use of these income-producing resources is irreversible. While the land above the resources is used for a transportation project, such as the I-290 Eisenhower Expressway, or other secondary development, these resources would not be available for extraction and use; therefore, they would be irretrievable.

While the state and federal funds and manpower that would be used to build the proposed project represent a monetary commitment, it is anticipated that the long-term economic benefits and traffic improvements that would result from the proposed project would outweigh this initial investment. Further analysis regarding the long-term economic benefit of the project is available in Section 3.1, Social/Economic Characteristics.

Overall, the use of these resources for the proposed project is warranted because construction of any of the build alternatives would provide long-term benefits, including improved local and regional mobility and connectivity and improved safety for all transportation modes within the Study Area. Ongoing planning and coordination with project stakeholders and resource agencies is helping guide the preliminary design of the transportation facility while minimizing impacts to local residents and natural resources. Implementation of the mitigation measures previously identified in the discussion of each resource topic presented in Section 3.0 would help offset unavoidable impacts to those resources, some of which are also protected by law, such as aquatic resources, wetlands, and historic resources.

3.18 Permits and Approvals

Since publication of the DEIS, the following substantive change to this section has been made:

- Identified the need for a NPDES permit for discharge to the Des Plaines River at the ComEd Maywood Technical Center.

This section summarizes permits and certifications applicable to the proposed project. Submittal of permit applications to pertinent regulatory agencies will take place after development of final engineering plans. Avoidance and minimization strategies required to obtain permits would be evaluated as part of the development of these final engineering plans.

The expected permits for this project include:

- Section 404 of the CWA (regional permit)
- Section 401 of the CWA (automatic with regional permit program)
- SWCD Review of Erosion and Sedimentation Control Plans
- NPDES Construction Permit
- Floodway and Floodplain Construction Permits
- IWPA-Related Approval
- FHWA Section 129 Compliance and Approval
- FHWA Access Justification Report and Approval

It is noted that the ComEd Maywood Technical Center currently has a NPDES permit (IL0059064) for discharge to the Des Plaines River. It is anticipated that any NPDES permitting needs due to the construction of Outlet #4 will be coordinated with IEPA during Phase 2 Design.

3.19 Summary of Environmental Commitments and Mitigation

There have been no substantive changes to this section since publication of the DEIS.

This section provides a brief description of the environmental commitments associated with the proposed project. This section also summarizes the mitigation measures to be provided in response to unavoidable adverse environmental impacts.

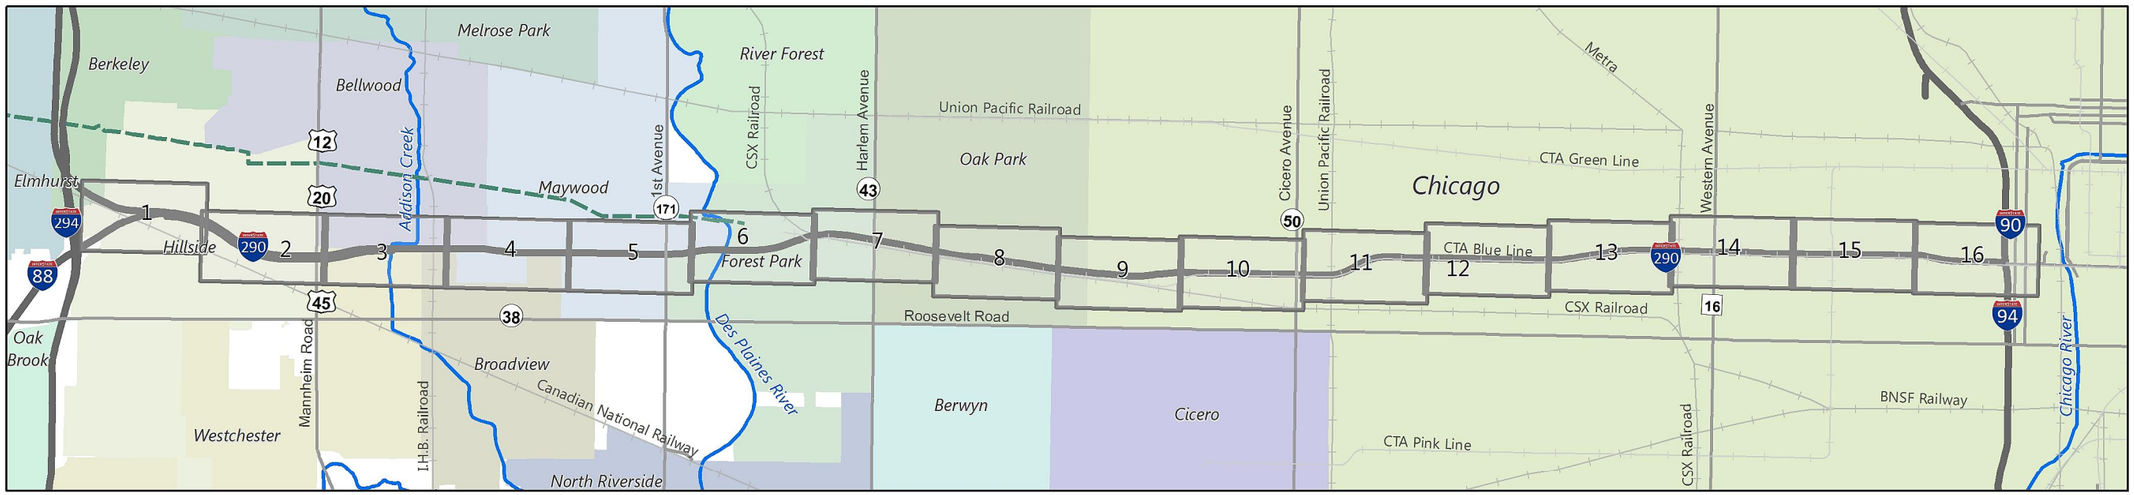
Table 3-53. Summary of Environmental Commitments

Impact	Mitigation Measure	Reference	Implementation Timing	Responsible Party*
Traffic Noise				
The build alternatives have only minor differences in traffic noise impacted receptors: GP Lane Alternative – 230 receptors; HOT 3+ Alternative – 229 receptors; HOV 2+ Alternative – 228 receptors; HOT 3+ & TOLL Alternative – 220 receptors; and the Preferred Alternative – 228 receptors. It is noted that the No Build Alternative would have 227 noise-impacted receptors.	The four build alternatives have very similar feasible and reasonable barrier design characteristics. The recommended locations of noise barriers associated with the Preferred Alternative are shown in the Section 3.0 Map Set. Of the 63 feasible and reasonable barriers, 46 walls were favored by benefited receptors in 2015 and 2016. IDOT intends to conduct additional outreach with local stakeholders during the project's design phase to determine the aesthetic treatment most appropriate for each community. Such future coordination may result in reopening the viewpoints solicitation process where warranted by changes in the number/location of benefited stakeholders, the benefited stakeholders' opinions, or noise wall technology.	DEIS Sections 3.4.3 and 5.3.7	Design and Construction	IDOT

Table 3-53. Summary of Environmental Commitments (continued)

Impact	Mitigation Measure	Reference	Implementation Timing	Responsible Party*
Natural Resources				
Construction of any build alternative will result in impacts to upland communities.	Impacts to trees will be minimized with installation of construction fencing and exclusion zones to reduce compaction of roots and soil. Mitigation for trees removed will be guided by IDOT's Preservation and Replacement of Trees (IDOT, 2002) policy and Chapter 59 ("Landscape Design") of the BDE Manual (IDOT, 2014). A landscaping plan will be developed during the design phase that will identify areas where trees, shrubs, and grasses will be planted on highway side slopes, on back slopes, and in the median, except where clear vision needs to be maintained at highway entrances and exits, intersections, and median openings.	DEIS Section 3.6.3 IDOT's *Preservation and Replacement of Trees* (IDOT, 2002) policy Chapter 59 ("Landscape Design") of the *BDE Manual* (IDOT, 2014).	Design and Construction	IDOT/ Contractor
Construction of any build alternative will minimally impact wildlife species.	Locations of short barrier walls near creek crossings to restrict the movement of small animals (including reptiles, amphibians, and smaller mammals) from entering the roadway corridor will be coordinated in the design phase. Design walls to not limit the movement of larger mammals and prevent them from being trapped within the roadway.	DEIS Section 3.6.3	Design	IDOT

Table 3-53. Summary of Environmental Commitments (continued)



Impact	Mitigation Measure	Reference	Implementation Timing	Responsible Party*
Floodplains				
Regulatory floodplain encroachments are negligible at the Des Plaines River (less than 0.1 acre-feet of fill for the normal to 100-year flood elevation). For Addison Creek, 17.1 acre-feet of floodplain cut volume will occur for the normal to 10-year flood elevation, and 4.1 acre-feet of floodplain fill volume will occur for the 10- to 100-year flood elevation. There will be a net cut volume for Addison Creek for the normal to 100-year flood elevation.	Retaining walls are proposed in key locations near the floodplains to minimize impacts. There is a net removal of floodplain fill at Addison Creek and the Des Plaines River floodways; therefore, no mitigation is necessary.	DEIS Section 3.9.3	Design	IDOT

Table 3-53. Summary of Environmental Commitments (continued)

Impact	Mitigation Measure	Reference	Implementation Timing	Responsible Party*
Visual Resources				
Construction of any build alternative will result in visual change at varying locations along the Project Corridor for motorists and for those viewers outside the corridor.	Mitigation for visual impacts may include implementation of context-sensitive design (that involves public input) and landscape improvements for replacement of existing landscaping, creation of new landscape areas, public input in the use of alternative materials and design of noise barriers, and installation of containerized plantings located on the cross-street overpass bridges. See also Traffic Noise mitigation above.	DEIS Section 3.13.5	Design	IDOT

Public Comments and Agency Coordination

June 2017

Illinois Department of Transportation

U. S. Department of Transportation
Federal Highway Administration

4.0 AGENCY COORDINATION AND PUBLIC INVOLVEMENT

Since publication of the Draft Environmental Impact Statement (DEIS), the following substantive changes to this section have been made:

- Addition of Section 4.4 to summarize the public hearings conducted for the DEIS; and
- Addition of Section 4.5 to summarize DEIS public and agency comments received.

Agency coordination and stakeholder involvement are critical to developing transportation improvement recommendations that address the needs of the Study Area. This section summarizes the agency and public involvement regulatory requirements, approach and methodology, and agency and stakeholder coordination conducted for the I-290 Study. Documentation of the project outreach and coordination with the public and local, state, and federal agencies can be found on the project website and in the project record.

A Context Sensitive Solutions (CSS) approach was developed to be responsive to the unique conditions and character of the Project Corridor. The approach was developed to facilitate the collection of substantive agency and stakeholder input, ensure that public concerns are duly considered, consider alternative modes of transportation, satisfy federal and state requirements, and work towards a consensus solution.

4.1 Outreach Requirements

4.1.1 Federal and State Requirements

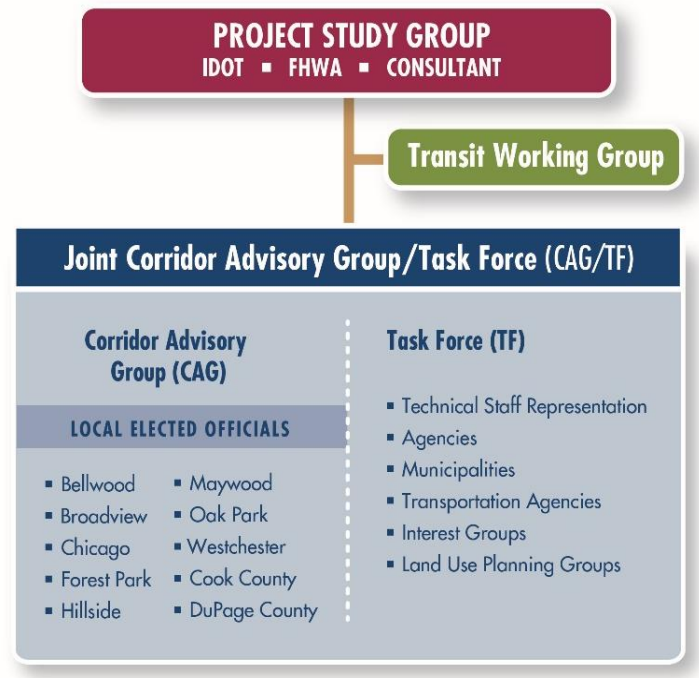
Preparation of this FEIS is in compliance with federal and state public involvement requirements. These include the following:

National Environmental Policy Act (NEPA)

- **23 USC 139**: Title 23 of United States Code (USC) – Pertains to regulations governing highway projects. Section 139 of Title 23 describes the process governing *Efficient Environmental Reviews for Project Decisionmaking.*
- **23 CFR 771**: *Code of Federal Regulations* (CFR) 771 – Describes the policies and procedures that Federal Highway Administration (FHWA) adheres to regarding implementation of NEPA for the processing of highway and public transportation projects.

Context Sensitive Solutions

- **605 ILCS 5/4-219**: Illinois Compiled Statutes (ILCS), Roads and Bridges, Chapter 605, Act 5, known and cited as the Illinois Highway Code, Article 4-219, states that context sensitive design and CSS be employed on Illinois Department of Transportation (IDOT) projects to ensure that projects meet the state's transportation needs, while existing in harmony with their surroundings, and add lasting value to the communities they serve.



4.1.2 Stakeholder Involvement Plan

A Stakeholder Involvement Plan (SIP) was developed to provide a framework for communicating the decision-making process between the general public, public agencies, and governmental officials with respect to this study. The SIP was made available to all stakeholders and was revised and updated periodically throughout the duration of the study. It can be found in the Project Reports section of the Information Center at www.eisenhowerexpressway.com.

4.1.3 Project Study Group

A Project Study Group (PSG) was established to lead the study. The PSG is comprised of multidisciplinary representatives from IDOT, FHWA, and the project consulting team. The PSG is tasked with determining the ultimate project recommendations and decisions (Figure 4-1). The PSG has a primary responsibility for following and implementing the project development process, including agency coordination and stakeholder involvement. This group collaborates throughout the Environmental Impact Statement (EIS) process to provide oversight and expertise in key areas, including study process, agency procedures, design standards, and technical evaluations. The PSG also has a primary responsibility for ensuring compliance with the SIP, promoting partnerships with stakeholders to address identified project needs, and developing consensus among stakeholders.

Figure 4-1. Project Working Group Structure

4.2 Corridor Advisory Group/Task Force (CAG/TF) Meetings

The PSG used a wide range of outreach methods for agency coordination and public involvement throughout the I-290 Study. However, the backbone of the I-290 Study public coordination process has been the Corridor Advisory Group (CAG). The CAG consists of representatives from each corridor community, transportation agencies, and interest groups, and meetings have been open to the general public. Twenty-one (21) meetings have been held with this group at, and in between, NEPA and various study milestones, and they are summarized in Table 4-1. As agency, municipal, and interest group representatives, the CAG participants played a key role in the identification, development, and refinement of build alternatives, including recommendation of a preferred alternative.

Table 4-1. Corridor Advisory Group/Task Force Meetings

Project Phase Key: **P = Purpose and Need; AD = Alternatives Development; AE = Alternatives Evaluation**
October 14, 2009 – CAG/TF Meeting #1 (P) An overview of the proposed project was provided followed by two breakout working sessions. The first session sought CAG input on concerns, issues, and deficiencies along the Project Corridor. The second breakout session asked CAG members to work in groups to identify goals and objectives for the project. Feedback received served as a basis for development of the project problem statement and ultimately the project Purpose and Need.
January 19, 2010 – CAG/TF Meeting #2 (P) A review of the Phase I Study Process and recap of the CAG/TF Meeting #1 and Public Meeting #1 comments was provided. The study approach and methodology for the technical analyses were presented, including travel demand model; travel demand forecasting; definition of the Study Area; and approach to analyze existing conditions of the major transportation elements including roadways, transit, freight railroads, nonmotorized travel, socio-economic, and land use. A draft problem statement was presented.
February 17, 2010 – CAG/TF Meeting #3 (P) An overview of the Phase I Study Process, including Data Collection, Purpose and Need, Alternatives Development and Evaluation, and selection of a Preferred Alternative, was presented. The draft Problem Statement was revised based on input from the CAG/TF members. The findings of the Cook-DuPage Corridor Study (2003-2009, by others) were reviewed. This study encompassed a broader, regional study area and included a Travel Market Analysis and Options Feasibility Study with a goal of establishing a framework to help guide future transportation planning. Part 1 of the I-290 Existing Transportation Systems Analysis findings was presented, including public transit, summary of the Cook-DuPage Corridor Study (2003-2009) findings, geometric deficiencies, drainage, and nonmotorized transportation.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

April 29, 2010 – CAG/TF Meeting #4 (P) Additional revisions to the Problem Statement, based on stakeholder input, were reviewed and the statement was finalized. The second part of the Existing Transportation Systems Analysis findings was presented, including preliminary operations and crash analysis results. A summary of the methodology and development of the travel demand model and forecasts for the build and no-build scenarios was presented. Formal development of the project Purpose and Need was initiated based on the CAG-developed Problem Statement and the findings of the existing transportation systems analysis report.
July 22, 2010 – CAG/TF Meeting #5 (P) Additional existing conditions operations and safety analysis findings were presented, including an in-depth look at the crash types and causes at specific locations within the project limits. A discussion of the Initial Needs of the corridor and five identified transportation project purpose and need points were reviewed. Copies of project Purpose and Need slides were distributed via e-mail for comment.
September 23, 2010 – CAG/TF Meeting #6 (P, AD) A draft outline of the project Purpose and Need was reviewed followed by a presentation of the proposed alternatives development and evaluation process that included several rounds of development and analysis for single mode and combination mode alternatives. Proposed transportation benefit and environmental evaluation measures were presented. An environmental inventory map was provided with known environmental features and constraints; stakeholders were asked to review the map and provide any additional information.
December 2, 2010 – CAG/TF Meeting #7 (P, AD) The Phase I Study process was recapped followed by a summary of the stakeholder comments received on the project Purpose and Need outline that was distributed to CAG members on November 24, 2010. An updated Purpose and Need outline, with revisions based on CAG input, was reviewed. The initial alternatives development and evaluation process was presented and initiated via a facilitated Alternatives Identification Workshop. CAG/TF members were provided with large-scale maps and various tools to assist sketching and describing various transportation alternatives and solutions to address the project Purpose and Need.
January 27, 2011 – CAG/TF Meeting #8 (P, AD) The draft Purpose and Need document was discussed, with a full draft to be prepared by the next CAG/TF meeting. A summary of the alternatives submitted by stakeholders at the Public Meeting, CAG/TF Meeting #7, and from the Cook-DuPage Corridor Study was presented, summarized by mode. A list of initial single mode alternatives to be evaluated with the travel demand model was reviewed. Typical section requirements for various transportation modes were presented and discussed.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

March 22, 2011 – CAG/TF Meeting #9 (P, AD) The Phase I Study process was recapped followed by an update to the Existing Transportation System Performance report. Updates included additional crash analysis at high crash locations and review of an additional report on the existing Americans with Disabilities Act (ADA) deficiencies in the Study Area. The Travel Model update from year 2030 to year 2040 was reviewed followed by an overview of the upcoming Public Meeting #2 agenda. A facilitated alternatives alignment and footprint workshop was conducted to review single mode alternative alignments and footprints, and to identify physical/environmental constraints and opportunities.
July 27, 2011 – CAG/TF Meeting #10 (AD, AE) A review of Public Meeting #2 was presented, including a summary of comments received. The process for evaluating Round 1 Single Mode Alternatives was presented, along with the initial list of Single Mode Alternatives selected for evaluation. These included nine transit, 11 expressway, and one arterial alternative. Concept-level footprints and a fatal flaw analysis of the alternatives were reviewed, as well as safety and travel performance measures from the travel demand model. A summary of the in-progress results was provided, with evaluations still ongoing.
September 29, 2011 – CAG/TF Meeting #11 (AE) A recap of the CAG/TF meeting format, and document review process was presented. The Round 1 Single Mode Alternatives Evaluation results presentation was continued from the previous CAG/TF meeting, starting with a recap of the alternatives screening process. A summary matrix of the Round 1 performance evaluation results was presented, categorized by each of the five purpose and need points. A results summary was distributed highlighting the four top-performing single mode transit and highway alternatives.
December 1, 2011 – CAG/TF Meeting #12 (AE) The Phase I Study process and progress was summarized, along with an update on the Purpose and Need document. A summary of the Round 1 analysis findings and overall conclusions was presented. Round 2 Combination Mode Alternatives evaluation was initiated with the identification of 10 initial combination mode alternatives to be evaluated with the travel demand model. The 10 alternatives combined highway, express bus, and high-capacity transit (HCT) modes.
March 15, 2012 – CAG/TF Meeting #13 (AE) The Phase I Study process and progress was recapped. Results of the 10 initial combination alternatives Round 2 evaluation were presented in additional detail. The alternatives scoring system was explained with overall scores calculated based on each Purpose and Need point, which carry equal weight. The top Round 2 combination mode alternatives were summarized and recommended for further refinement and evaluation. The interchange and access evaluation approach was presented.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

June 11, 2012 – CAG/TF Meeting #14 (AE) The Phase I Study process and progress were summarized followed by a review of the Round 1 and initial Round 2 findings. The CAG requested that two additional combination alternatives be evaluated as part of the Round 2 evaluation. Round 3 evaluation approach was presented, which would further refine and evaluate the top Round 2 performing alternatives, adding in additional design detail. The objective of Round 3 was introduced, which is to determine the refined Round 2 alternatives to be carried forward for detailed analysis in the DEIS. The extension of the eastern limit of the Study Area to the Jane Byrne (formerly Circle) Interchange project limit was also discussed. A facilitated interchange and access workshop was held to review initial interchange configurations and access concepts, identify any issues or concerns, and identify any other potential interchange designs or access configurations.
February 22, 2013 – CAG/TF Meeting #15 (AE) The Phase I Study process and progress were recapped. An update of the Round 2 combination mode alternatives was presented that included the analysis of two additional alternatives requested by the CAG. From the 12 Round 2 Alternatives, the four top-performing combination mode alternatives were selected for further evaluation in Round 3. An overview of the interchange and access design and local coordination was provided. The Study Area was formally extended to Racine Avenue, and a summary of existing conditions for the expanded Study Area section was provided. Round 3 screening analysis approach was revisited followed by a discussion of environmental factors to be included as part of Round 3 evaluation. Chicago Transit Authority (CTA) introduced the Blue Line Forest Park Branch Feasibility/Vision Study (Blue Line Vision Study) and the steps that would be taken to study the existing and future market potential and condition needs of the Forest Park Branch; the results are intended to inform the I-290 Study.
July 17, 2013 – CAG/TF Meeting #16 (AE) A summary of Round 2 comments was provided, along with responses to several stakeholder questions, including right-of-way impacts, left-side ramps, livability in the project Purpose and Need, congestion relief, congestion pricing, urban design, Blue Line extension, land use and travel markets, and environmental justice. Renderings of the Austin Boulevard and Harlem Avenue interchange concepts were displayed. An alternate Round 2 scoring methodology (ratio scoring) was presented and resulted in the same four top-performing alternatives as the original scoring method (ordinal). The final Round 3 alternatives to be evaluated in the DEIS were presented, along with a recap of the evaluation activities proposed as part of Round 3. CTA provided an update in the CTA Blue Line Vision Study. A facilitated Bike and Pedestrian workshop was held after the CAG meeting to further detail existing conditions and identify stakeholder issues and needs related to improved bike and pedestrian facilities.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

September 4, 2013 – CAG/TF Meeting #17 (AE) A summary of the bike and pedestrian workshop results was presented followed by a presentation from CTA on the status of the Blue Line Vision Study. After the CTA presentation, IDOT stepped through a detailed presentation on geometrics associated with the proposed interchange and access concepts, as well as the mainline reconstruction and restriping sections. This included an overview of design standards and design exceptions. Geometrics was followed by a presentation on the proposed air quality analysis approach, an introduction to aesthetics, and a review of the Highway Safety Manual (HSM) and applicable crash reduction factors. The agenda for the upcoming third public meeting(s) was reviewed (October 7 and October 8, 2013). Large-scale exhibits of the overall proposed expressway, interchange, and cross-road concept were available for CAG review, and PSG representatives were available to answer questions.
July 30, 2014 – CAG/TF Meeting #18 (AE) The Phase I Study process and progress were recapped, followed by a summary of Public Meeting #3. The four DEIS build alternatives were reviewed highlighting the identified key project benefits. Transit, safety, managed lanes, funding, and construction with respect to a build alternative were discussed. CTA provided an update on the Blue Line Vision Study that included a summary of overall recommendations for the Blue Line modernization. IDOT then presented detailed Round 3 alternatives evaluation findings, including expressway and arterial average daily traffic (ADT), expressway travel times, safety performance, transit ridership, construction cost estimates, vehicle hours of travel (VHT), and productivity savings. An evaluation of the west end operational analysis and a proposed west end mainline lane configuration concept was presented. A summary of delay and queue improvements for the proposed interchange concepts was reviewed, followed by an overview of existing drainage issues and proposed drainage concepts, mainline profile adjustments at Harlem Avenue and Austin Boulevard, and a shared-use trail connection concept at Columbus Park. The Traffic Noise Analysis process was explained and included an overview of how noise is measured and perception of sound levels. Traffic noise regulations and the noise analysis steps were summarized. The findings of a noise sensitivity analysis for left- versus right-hand ramps were provided. The meeting concluded with a discussion of upcoming local cross-road aesthetic coordination and a distribution of plan and profile geometric packages (plans, profiles, cross sections) for CAG review and comment.
September 24, 2014 – CAG/TF Meeting #19 (AE) The Phase I Study process and progress was recapped followed by an update on the ongoing Round 3 alternatives evaluation. An overview of the content of an EIS was provided. The remainder of the CAG/TF meeting presentation focused on the existing and proposed drainage. This included a description of the current expressway drainage system design, deficiencies and flooding issues, and an assessment of municipal areas that drain to the expressway system during larger storm events. Sets of existing drainage plans were provided to each municipality, and to others as requested, for review and comment regarding documentation of known drainage issues and location of drainage features.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

August 27, 2015 – CAG/TF Meeting #20 (AE) The Phase I Study process and progress were recapped followed by an update on the CTA Blue Line Vision Study final findings presented by CTA. IDOT provided a crash analysis update that included 2013 crash data. Crash analysis was followed by a detailed summary of the proposed frontage road and ramp access configuration between 1st Avenue and 25th Avenue and resulting average local travel distance changes. Air quality analysis results were presented, including the results of a regional project air quality sensitivity analysis for each DEIS build alternative, and a carbon monoxide (CO) intersection sensitivity analysis. A noise analysis update was provided that included a summary of the existing versus no build condition noise levels and a discussion of upcoming build conditions analysis and noise wall viewpoint solicitations. An overview of Section 106, Section 4(f), and Environmental Justice (EJ) considerations was provided, including project applicability and considerations. The presentation concluded with an overview of the aesthetic approach for the mainline expressway and cross roads.
October 15, 2015 – CAG/TF Meeting #21 (AE) The Phase I Study process and progress were recapped followed by conclusions of the Round 3 analysis of the DEIS alternatives. Air quality results for Mobile Source Air Toxics (MSAT), and quantitative $PM_{2.5}$ analysis of the alternatives were summarized. Noise analysis results for the four DEIS alternatives were provided. An overview of the EJ policies and principles, and a summary of the effects and benefits of the build alternatives were presented. A preliminary preferred alternative was identified based on completion of the Round 3 evaluation and a comparison of results. This included a summary of how the preliminary preferred alternative meets the stakeholder goal and objectives identified at the beginning of the CAG process. Noise abatement analysis process and results for the preliminary preferred alternative were presented to the CAG, indicating where noise walls were found to be reasonable and feasible. Noise wall viewpoint solicitations are the next step in the process. Three public Noise Wall Forum Meetings were scheduled to provide information and answer stakeholder questions on the noise wall process. The final presentation topic was an overview of Intelligent Transportation System (ITS) concepts that are being considered in the Project Corridor and potential off-system arterial improvements that could be implemented in conjunction with the expressway improvements.

Table 4-1. Corridor Advisory Group/Task Force Meetings (continued)

December 14, 2016 – CAG/TF Meeting #22 (AE) An overview of the DEIS and a summary and status of the CTA Blue Line Forest Park Branch Vision Study were presented. The DEIS overview reviewed the purpose and need, alternatives evaluation process, a description of the No Build Alternative and four DEIS build alternatives, and identification of the HOT 3+ Alternative as the Preferred Alternative. A summary of how the HOT 3+ Alternative addressed stakeholder goals and the problem statement was provided. Summary findings from the DEIS for EJ, air quality, traffic noise, special lands, indirect and cumulative impacts, Section 106, and comments and coordination were presented. An overview of the construction approach, including advance work, a conceptual construction schedule, and construction effects mitigation, was presented. CTA and CSX design coordination and the use of FHWA's INVEST sustainability tool were summarized. Next steps and schedule were provided, including the DEIS release, public hearing dates, locations, format, end of the DEIS comment period, and release of the combined Final Environmental Impact Statement (FEIS)/Record of Decision (ROD). It was also noted that Phase II design and Phase III construction are not funded. The CTA Blue Line Vision Study summary included community outreach, recommendation summaries for single-entry stations, infrastructure, station design, construction approach, and next steps.

4.3 Stakeholder, Community, and Agency Coordination

This section summarizes other stakeholder, community, and agency coordination and outreach that occurred as part of the I-290 Study.

4.3.1 Stakeholder Outreach

In addition to the CAG meetings, a range of other outreach and coordination approaches were used that provided additional layers and coverage of stakeholder participation in the study process. These included one-on-one meetings with individual project stakeholders, village boards, village staff working groups, agency meetings, interest groups, town hall meetings, public hearings, and more. A summary of the outreach methods is provided in Table 4-2, with more detailed documentation provided on the project website in the Public Involvement Record.

Table 4-2. Summary of Outreach Methods (as of April 2017)

Outreach Method	Quantity
Stakeholder Mailing List Members	6,959
Project Website – Visits	74,330
Newsletters and Fact Sheets	6
Media Releases and E-Mail News	4 and 69
Community Stakeholder Meetings	135
Agency Stakeholder Meetings	54
NEPA/404 Merger Meetings	6
Transit Working Group Meetings	10
Public Meetings	3
Public Hearings (1 Round at 2 Locations)	2
Speaking Engagements	11
Public Comments Received and Considered	1,787

Public Meetings. Public meetings were held at three different times during the study (Table 4-3). The meetings were held in more than one location within the Study Area to provide additional opportunity and flexibility for public input. Facilities were ADA compliant, easily accessible by public transportation, and located within the Project Corridor.

Table 4-3. Public Meetings

November 18, 2009 – Public Meeting #1: As part of the scoping process, the project team sought stakeholder input on the transportation issues and concerns as it relates to the I-290 Study. The feedback received, coupled with data collection, allowed IDOT and stakeholders to identify transportation deficiencies and begin the process for developing solutions to address these needs.
May 18, 2011 – Public Meeting #2: Highlights of Public Meeting #2 include an explanation of the EIS process, project phases, public involvement opportunities, CSS process, data collection, needs analysis, initial alternatives identification and development, environmental constraints, single mode alternatives analysis, transit suggestions, and suggested arterial improvements.
October 7 and 8, 2013 – Public Meeting #3: Highlights of Public Meeting #3 include expansion of the Study Area, public involvement activities, Purpose and Need recap, Round 2 alternatives development and evaluation process, identification of four finalist alternatives, Round 3 evaluation criteria, proposed Harlem/Austin interchange designs, air quality and noise analysis process, and the CTA Blue Line Vision Study.

Environmental Justice. The PSG worked to ensure full and fair participation opportunities by all potentially affected communities and stakeholders in the study process. Special effort was also made to advertise the public meetings within EJ communities. In addition to regular meeting notices in newspapers, libraries, and public agency offices, advertisements were also posted in places of worship, laundromats, and local convenience stores. Public meeting notices and website content were also provided in Spanish, and Spanish translation services were available at the public meetings.

Other means of communicating and coordinating with the public, including EJ populations, have been utilized. These additional outreach efforts include:

- Use of a project website (www.eisenhowerexpressway.com) to disseminate information to the public and receive input and comments. This website provides a central source of project study information and documents, and is available to anyone at any time with access to the internet. Key project information is also translated in Spanish on the website;
- Distribution of four project newsletter/fact sheets at key project milestones to all contacts on the project mailing list, including federal, state, and local officials; special interest groups; resource agencies; business and community leaders; and members of the public (Fall 2009, Spring 2011, Spring 2013, and Fall 2014);
- Use of media outlet press releases, media briefings, publication pieces, media correspondence, and briefings with agency-designated spokespersons to inform the general public about the proposed project and its progress. To specifically reach minority populations regionally, press releases were sent to targeted radio, print, and television outlets;

- Advertising the public meetings on digital billboards along I-290; and
- Focused outreach in the Village of Maywood to address access issues brought about by the interchanges proposed between 25th and 1st avenues. Section 4.3.2, Community Coordination, provides a description of the process used to address the stated concerns.

Primary concerns from EJ communities include access to I-290, improving their local economy, and the ability to directly benefit from reconstruction of the Eisenhower Expressway in the form of jobs and job training. To address these concerns, representatives from IDOT's community college career training program attended the I-290 public meetings. IDOT has also spoken about the I-290 Study at four town hall meetings and a civic group meeting since 2009. The Maywood Advisory Group was formed to address I-290 access concerns as previously stated.

Other EJ concerns expressed at meetings include economic and business impacts (existing I-290 access will be maintained, and improved 1st Avenue interchange operations), community connectivity (1st Avenue interchange and 5th, 9th, and 17th avenue I-290 cross-road bridges would have wider sidewalks and improved bicycle, ADA, and pedestrian facilities), Village of Maywood residential drainage/flooding issues due to undersized combined storm and sanitary sewer system (proposed I-290 drainage improvements have potential for reducing flooding in 141 acres in Maywood), access to transit (wider sidewalks and improved ADA and pedestrian facilities to improve CTA station access), and financial impacts on the residents (accessibility and shorter access to jobs with I-290 improvements).

Noise Wall Forums. Three noise wall forums were held to publicly share and explain findings of the noise impact and abatement analysis prior to viewpoint solicitation. The meetings were conducted in an open-house format followed by a live presentation and facilitated question-and-answer session. Large-scale maps of proposed improvements, noise wall locations, and locations of the benefited properties were available. Also available were boards showing the Phase I Study process and noise wall solicitation process, and a video of before and after noise wall visualizations. The visualizations included relative sound differences playing on a speaker. PSG representatives were available to answer questions. The noise wall forums were held in Chicago, Oak Park, and Hillside in October 2015, with a follow-up event in Maywood in August 2016.

Legislator Town Hall Meetings. There were four public "town hall" meetings requested by state legislators and held within their districts, with presentations by the PSG and question-and-answer periods. These meetings occurred in December 2009 **(**Representative La Shawn Ford), October 2013 (Senator Don Harmon), and April 2014 and January 2015 (Senator Kimberly Lightford). There were various purposes of the meetings, including introducing and providing an overview of the I-290 Study; initiating a dialogue with residents who live near the Eisenhower Expressway, community leaders, and advocacy groups; providing additional presentations by CTA and Citizens for Appropriate Transportation; and discussing proposed improvements that directly

impact Maywood. These meetings served to connect state legislators, their constituents, and the PSG in sharing project information and addressing questions.

4.3.2 Community Coordination

Small group one-on-one meetings and broader audience meetings were held with the City of Chicago and the seven other Project Corridor communities. The individual meetings were initiated in 2009 and held throughout the study process at NEPA milestones and other project decision points to solicit comments, brief local officials on the study progress, answer questions, identify local issues and needs, and develop and refine project elements. The following summarizes the outreach efforts with respect to community coordination.

Hillside. Hillside's primary project concerns were existing local street flooding issues in the vicinity of I-290 and the extension of the CTA Blue Line. The project team worked with village staff to identify the cause of drainage issues and develop a plan to address the issues. The accommodation of a future HCT extension along I-290 to Mannheim Road was coordinated with Hillside planners.

Bellwood. Bellwood's primary project concerns were associated with expressway access at 25th Avenue and potential redevelopment of the vacant Wilson School property in the northeast quadrant of the 25th Avenue interchange. The project team worked closely with village officials to configure the proposed 25th Avenue interchange to accommodate future development plans.

Westchester. Westchester's primary project concerns were related to flooding along Addison Creek and the condition of Mannheim Road. The project team coordinated the expressway and 25th Avenue interchange design with village staff. I-290 does not currently drain to Addison Creek and is not proposed to drain to Addison Creek under the proposed drainage design. IDOT will continue to coordinate with the village on patching work for Mannheim Road in advance of I-290 reconstruction.

Broadview. Broadview's project concerns include design of the 25th Avenue interchange, maintaining expressway ramp access to and from the east at 17th Avenue (for access to their retail development at Cermak Road), flooding conditions along the Des Plaines River/Salt Creek/Addison Creek, and pavement flooding at Indian Joe Drive west of the 25th Avenue interchange. The project team coordinated 25th Avenue and 17th Avenue interchange designs to incorporate and improve the desired access at these locations, as well as addressing parking and circulation concerns along Bataan Drive, which included adding a northbound right-turn lane at 17th Avenue onto Bataan Drive. The project team addressed village concerns regarding project effects on Des Plaines River flooding and coordinated the proposed drainage plan to help address flooding issues along Indian Joe Drive.

Maywood. Coordination with Village of Maywood staff occurred throughout the study process and included a Town Hall meeting in January 2015. In December 2015, a second town hall meeting was held where concerns were raised by stakeholders regarding the

proposed I-290 ramp access concept. To address these concerns the Maywood Advisory Working Group (AWG) was formed consisting of PSG representatives, Village of Maywood staff, village trustees, state representatives, and local citizens. The project team worked closely with the village staff and AWG to develop and evaluate access alternatives and assess benefits. The AWG process resulted in a revised alternative recommendation that retains the existing I-290 ramp connections at 9th and 17th avenues, while providing overall mobility improvements to the community. Detailed traffic models and traffic video simulations were developed to evaluate and demonstrate the effects of the improvements.

Other concerns addressed by the AWG were related to improving traffic conditions at 1st Avenue, providing a safe crossing of 1st Avenue at the Illinois Prairie Path, ensuring that access to business corridors in the community were maintained or improved, providing local flooding relief, and noise walls. Drainage improvements that could benefit both IDOT and the Village were also identified with the support of the Village and the Metropolitan Water Reclamation District of Greater Chicago. Overall, this 8-month extended outreach period with Maywood included five AWG meetings, eight village staff meetings, and two additional town hall meetings.

Forest Park. Forest Park's primary project concerns were related to CTA Blue Line Terminal access, operational improvements along DesPlaines Avenue, bike and pedestrian improvements along DesPlaines Avenue and Circle Avenue, and operational improvements at Harlem Avenue. The project team worked closely with the Village planners and CTA to coordinate DesPlaines Avenue improvements with the existing and future CTA terminal development. Improved bike and pedestrian accommodations desired by the Village are incorporated at DesPlaines Avenue, Circle Avenue, and Harlem Avenue. In particular, proposed bike and pedestrian features along these arterials will help achieve village goals of improving connectivity over the expressway and to the Park District of Forest Park facility adjacent to and south of the expressway.

Oak Park. The Village of Oak Park has been actively involved throughout the study process. In response to December 2014 correspondence that provided village comments on the concept plan and profile geometry, the Oak Park Working Group (OPWG) was formed. The OPWG consisted of PSG representatives, CTA staff, village staff, elected officials, and trustee members. Village concerns addressed include Harlem Avenue and Austin Boulevard interchange operations and ramp design, expressway elevation and cross-road profiles, air quality impacts, noise walls, drainage, utilities, bicycle and pedestrian features, aesthetics, expressway decking, CTA station accommodations, and construction impacts.

The OPWG met 21 times from February 2015 to August 2016 to systematically work through the issues and concerns raised by the Village of Oak Park and to develop a consensus plan. Presentations were also made by IDOT and Village staff at 10 Village Board Study Session meetings from January 2015 to July 2016 to publicly communicate the OPWG progress and to address any other issues raised by the Board. Visualizations, including traffic simulations, 3-D fly-through animations, and scale 3-D printed models,

were prepared by the PSG to respond to concerns raised by the village. At the August 1, 2016, Village Board meeting, the village approved the preferred mainline alternative along with other project elements proposed within the village limits.

City of Chicago. The PSG met individually with the aldermen of the 2nd, 24th, 25th, 27th, 28th, and 29th wards that border the expressway; CTA and the Chicago Department of Transportation (CDOT) were also invited. Concerns of the Wards included the noise impact and abatement process (including viewpoints solicitation voting), potential effects of the project on arterial traffic, improvements and connectivity of the CTA Blue Line and other transit services in conjunction with the project, and the managed–lane component of the build alternatives.

Cook County Department of Facilities Management. The PSG met with Facilities Management to discuss the status and mitigation of parking spaces at the State of Illinois Circuit Court of Cook County Fourth Municipal District Maywood Courthouse that would be impacted by widening of I-290 east of the 1st Avenue interchange.

4.3.3 Agency Coordination

Coordination with other transportation providers, local and regional transportation agencies, and regulatory agencies has been undertaken to ensure that the proposed improvements to I-290 are operationally consistent with other transportation facilities and services potentially affected by the project. A summary of this coordination follows.

Transit Working Group (TWG). Due to the multimodal nature of the Project Corridor, a TWG was established to provide coordination with relevant service providers throughout the study process. The TWG included the Regional Transportation Authority (RTA), CTA, Metra, Pace, the Illinois Tollway, and Chicago Metropolitan Agency for Planning, who are also all members of the CAG/TF. The PSG coordinated with the TWG regarding all phases of the study process, ranging from Purpose and Need to alternatives identification and evaluation. The TWG met 10 times during the course of the study.

Chicago Transit Authority. Extensive and continuous coordination occurred between IDOT and CTA regarding a potential extension of the Blue Line, configuration of transit in alternatives development and refinement, and coordinating the modernization goals of the existing Blue Line Forest Park Branch with the proposed I-290 improvements. IDOT supported and coordinated closely with CTA's Blue Line Vision Study to ensure that the goals of the Blue Line Vision Study were accommodated and supported by the proposed project. CTA's primary project concerns with respect to expressway improvements were Blue Line head station access/interface improvements, coordinating improvements to, or redevelopment of, the Forest Park Terminal/yard/shop facility, bus accommodations and transfers, and availability of vacant CTA right-of-way for I-290 improvements.

CTA is a member of the CAG/TF and presented at several meetings, was a member of the TWG, and attended many of the I-290 one-on-one municipal coordination meetings, town hall meetings, and working group meetings. CTA worked with the project team early in the alternatives development process to determine Blue Line extension opportunities and feasibility, Blue Line Terminal concepts, bus transfer locations and configuration, station/platform design, ADA improvements, bus stop locations, expanded bus layover/waiting areas, shelters, crosswalks, and use of vacant CTA right-of-way for expressway improvements.

Regional Transportation Authority. RTA has been a regular member of the CAG/TF and TWG. The PSG met with RTA individually during the initial phases of the study. Project coordination was related to the Purpose and Need statement and alternative identification.

Pace. Pace has been a regular member of the CAG/TF and TWG. The PSG met with Pace individually during the study process. Project coordination included provision of express bus service along I-290 either on a shoulder or in a managed lane, bus pull outs/waiting areas at the Cicero Avenue U-turn, and provisions of improved bus transfers on bridges. Pace worked with the project team to configure the express bus and feeder bus transit components in the build alternatives, as well as bus transfers at specific locations.

NEPA/404 Merger Team. The Illinois NEPA/404 Merger Process was instituted in 1996 by FHWA and IDOT to provide concurrent review of federally funded transportation projects requiring an environmental assessment or EIS and an individual Section 404 permit. It includes regularly scheduled meetings held with representatives of state and federal regulatory agencies, including the US Army Corps of Engineers (USACE), US Coast Guard (USCG), US Environmental Protection Agency (EPA), US Fish and Wildlife Service (USFWS), the Illinois Department of Natural Resources (IDNR), the Illinois Department of Agriculture (IDOA), and the Illinois Environmental Protection Agency (IEPA). Projects are presented to the agencies for discussion and concurrence during various stages of development.

Early in the I-290 Study process, the NEPA/404 Merger Team concluded that the I-290 Study would not require formal concurrence by the Merger Team because an individual Section 404 permit is not required. It was agreed that an EIS would be prepared to address public concerns, while the PSG would periodically update the NEPA/404 Merger Team at key study milestones (e.g., Purpose and Need, Alternatives to be Carried Forward to the DEIS, and the Preferred Alternative). Few environmental permits were anticipated given the limited presence of protected environmental resources in this developed, urban corridor. A summary of NEPA/404 Merger Team meetings is provided in Appendix K.

US Environmental Protection Agency. The USEPA has been a regular member of the CAG/TF. Coordination with the USEPA also occurred throughout the study process via presentations at NEPA/404 Merger Team Meetings and one-on-one meetings. The

USEPA's primary interest was the consideration of EJ communities in alternatives development and evaluation, and that EJ is adequately addressed in the DEIS.

Illinois Tollway. Project interests were primarily related to the interface with their facilities and the configuration of managed lanes and tolling in alternatives development. Coordination with the Illinois Tollway included how I-290 improvements would affect connections with I-88 and I-294, and in particular where managed lanes would begin and end in the west end of the Study Area. The Illinois Tollway was a regular participant in the CAG/TF meeting process and the TWG. The PSG also met with the Illinois Tollway individually during the study.

Illinois State Police (ISP). The PSG consulted the ISP throughout the study process to discuss expressway crash analysis and safety concerns, enforcement areas, and location and design of Accident Investigation Sites (AIS) for the Preferred Alternative. Several enforcement locations were identified for the Preferred Alternative as well as identifying several desirable AIS locations in the reconstruction section.

Cook County Department of Transportation and Highways. Cook County's project interests were primarily related to how county-maintained frontage roads would be affected by the proposed improvements and the desire to transfer jurisdiction of remnant sections of county-maintained frontage roads to local agencies in conjunction with this project. The project team coordinated the scope of frontage road improvements with Cook County and local governments regarding potential jurisdictional transfers.

DuPage County Division of Transportation. DuPage County's project interests included transit connections, the Illinois Prairie Path, and the I-290/I-88/I-294/North Avenue connections. DuPage County has also been a regular participant at CAG/TF meetings.

Chicago Department of Transportation. CDOT has been an active participant in the CAG/TF meetings, and the PSG also met individually with the agency. Their primary project focus was with the design and operation of the Laramie/Cicero and Austin interchanges; ADA/pedestrian treatments at intersections; and arterial performance.

Chicago Park District. Coordination with the Chicago Park District was primarily focused on the proposed project elements adjacent to Columbus Park and the proposed shared-use path connection to the Columbus Park trail system. As described in Section 3.12, Special Lands, no impacts to Columbus Park are anticipated; however, the Chicago Park District has been interested in the alignment and profile of the Austin Boulevard and Central Avenue ramps and the connection of the proposed shared-use path to the west end of Columbus Park. Coordination with the Chicago Park District is ongoing to provide enhancements along the southern edge of the park in conjunction with the expressway reconstruction.

CSX, IHB, and Other Railroads. Coordination with the CSX Railroad included discussion of the potential to reallocate or obtain portions of their existing operational envelope (right-of-way), discussion of railroad vertical clearance requirements beneath

the cross-road bridges from Central Avenue and DesPlaines Avenue, and their I-290 bridge crossing. Through the study process, the PSG coordinated with CSX to develop and refine a concept that would improve vertical clearances to a minimum of 21-feet 9-inches, improve drainage and decrease flooding exposure, and avoid CSX right-of-way impacts without the need to raise cross-road profiles, which would have impacted property in Oak Park and Forest Park.

Coordination with the Indiana Harbor Belt (IHB) Railroad occurred regarding proposed design changes to their four-track crossing of I-290 west of the 25th Avenue Interchange. To accommodate the future expressway footprint and clearances, the IHB bridge will be widened and the profile raised several feet to accommodate longer and deeper beams. The IHB stipulated that only one track may be taken out of service at a time, and IDOT undertook additional survey and design coordination to minimize profile grade increases in accommodating the raised crossing of I-290.

IDOT also coordinated with the Belt Railway Company of Chicago (BRC) and the Canadian National (CN) Railway regarding their operations and facilities, including I-290 bridge crossings.

Cook-DuPage Corridor Study. The West Central Municipal Conference, in conjunction with the DuPage Mayors and Managers Conference, is conducting a long-range transportation planning study of a 300-square-mile study area extending from Cicero Avenue on the east to the Kane-DuPage county line on the west. The PSG coordinated with the Cook-DuPage Corridor Study regarding travel forecasting, alternatives identification and evaluation, and smart corridors.

4.4 Public Hearing

Two public hearings on the I-290 DEIS were held at two different locations on consecutive days. The DEIS documented the need for transportation solutions for I-290 from west of Mannheim Road to Racine Avenue and the evaluation of alternatives for addressing those transportation needs. Further, it described the potential effects on community and environmental resources and the potential effects on future traffic operations caused by proposed build alternatives as well as the No Build Alternative. The findings from the CTA's Blue Line Vision Study were also presented. A Notice of Availability (NOA) was issued on December 30, 2016 in the Federal Register. The NOA started the 45-day public review and comment period.

The public hearings were conducted in an open-house format, and interested persons could attend anytime between 5:30 p.m. and 8:30 p.m. Attendees had the opportunity to view a continuous audiovisual presentation and exhibits as well as provide written or oral comments on the DEIS, alternatives under consideration, preliminary road closure plan, social, economic, environmental effects and proposed mitigation strategies, and proposed Section 4(f) *de minimis* impacts at three public park locations in Forest Park. IDOT and project team representatives were available to answer questions; CTA representatives were also available to answer questions pertaining to the Blue Line

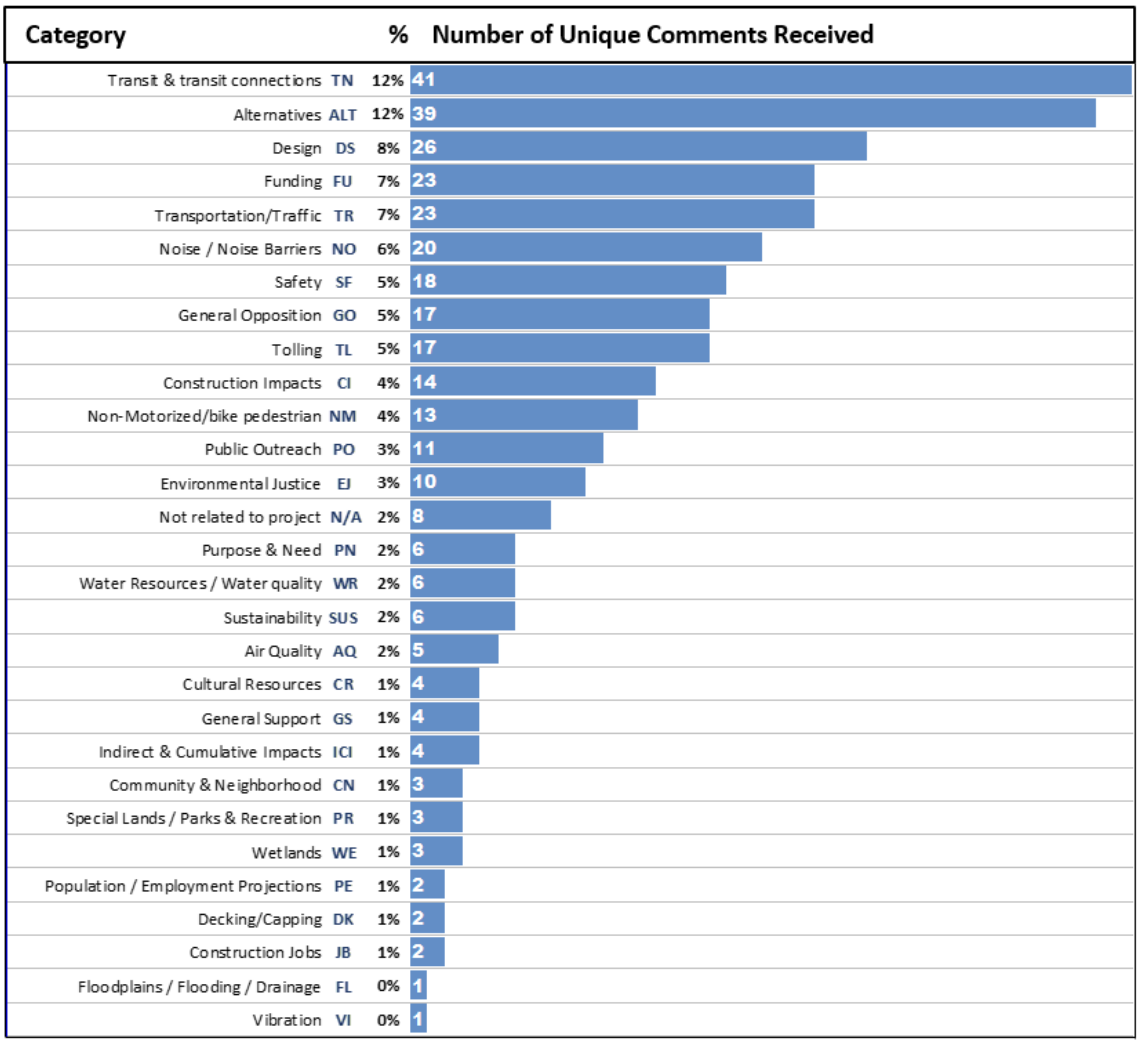
Vision Study. In addition, a question and answer forum was held at 7:00 p.m. each day. Court reporters were available to record public comments. The public hearing dates and locations are listed in Table 4-4.

Table 4-4. Public Hearings

January 25, 2017 – Public Hearing #1:	**January 26, 2017 – Public Hearing #2:**
Proviso Math and Science Academy 8601 Roosevelt Road Forest Park, Illinois	Marriott Chicago - Medical District 625 South Ashland Avenue Chicago, Illinois 60607

A total of 281 people attended the public hearings with a total of 17 people participating with comments or questions in the 7:00 p.m. question and answer sessions.

4.5 Summary of Comments and Responses on the DEIS



The public comment period for the DEIS was initiated on December 30, 2016 with the issuance of the NOA in the Federal Register, extending for 45 days and closing officially on February 13, 2017. However, five comments were received after that date, were included in the project record, and are addressed in this FEIS. Approximately 332 unique comments were received from federal agencies, local governments, individuals, and organizations. Unique comments were identified by annotating the 124 total comments received into discrete comments by topic that could then be responded to individually as a standalone comment. Thus, a single comment submitted could contain multiple unique comments as shown in Appendix N with a response for each unique comment in Appendix O.

Approximately 65 percent of the DEIS comments were received from individual stakeholders representing themselves, followed by 24 percent from public organizations, 6 percent from federal agencies, and 5 percent from units of local government. No state agencies commented on the DEIS.

The subjects of the comments were varied, and were grouped into over 30 categories for analytical purposes. The major comment categories are shown in Figure 4-2 and included: transit and transit connections (12 percent); alternatives (12 percent); design issues (8 percent); funding (7 percent); transportation/traffic (7 percent); noise and noise barriers (6 percent); safety (5 percent); general opposition (5 percent); tolling (5 percent); construction impacts (4 percent); nonmotorized transportation (4 percent); public outreach (3 percent); and environmental justice (3 percent). Fourteen other categories represented the remaining 19 percent of comments.

Annotated comments received on the DEIS can be found in Appendix N of the FEIS and a comprehensive table containing comments and responses to each can be found in Appendix O.

Figure 4-2. DEIS Public Comments by Category

4.5.1 Federal Resource Agency Comments

Three federal resource agencies and one Native American tribe submitted comments during the DEIS comment period. Detailed federal resource agency comments are on pages N-1 through N-13 in Appendix N and IDOT responses are on pages O-1 through O-11 in Appendix O. Following is a summary of the comments received and IDOT's responses.

US Environmental Protection Agency (USEPA). The USEPA commented on the demographics used for social/economic analysis within the Study Area; discussed mitigation of tolling for low-income users; discussed childrens' and others' exposure to air quality during construction, lead-based paint removal and traffic noise health risks during construction and mitigation thereof; equipment exhaust and dust emissions during construction and mitigation thereof; included recommendations for a community liaison program and continued public involvement during construction; and

commended the context sensitive process and included additional recommendations for final design elements.

In response, IDOT and USEPA held a teleconference on May 10, 2017 to share revised response language to address the concerns in USEPA's February 10, 2017 DEIS comments. USEPA concurred with the revised responses via email on May 31, 2017. The DEIS comment responses in Appendix O include the language concurred with by the USEPA; these responses are also reflected in the content of the FEIS as described below. IDOT included requested revisions to the demographic data summary and presentation in the FEIS, and clarified that the tolling policies, and any mitigation thereof, would be addressed in more detail in Phase II design. Regarding mitigation of construction activities as they relate to childrens' health, lead testing & releases, construction noise, construction emissions, and fugitive dust control, IDOT responded that their standard construction specifications already address most of these concerns. Because Phase II (design) and Phase III (construction) are not funded at this time, and that there could be a considerable gap between the ROD and the initiation of Phase II, it would be premature to develop a detailed set of commitments at this time, especially prior to engaging in Phase II engineering. However, IDOT responded that they will develop a series of "Special Design and Construction Considerations" that are listed in the Combined Design Report (CDR), which is the engineering document that is companion to the EIS.

US Department of the Interior (DOI). The DOI noted the proposed Section 4(f) *de minimis* impacts in Forest Park and Section 4(f) temporary occupancy in Columbus Park to accommodate improvements associated with the I-290 project, and stated the need for formal written concurrence from the Village of Forest Park, the Chicago Park District, and State Historic Preservation Office (SHPO). The DOI noted five properties and one historic district within the project's Area of Potential Effects (APE) and recommended consultation with SHPO. The DOI stated its finding that park lands previously improved with Land and Water Conservation Fund (LWCF) Act and Urban Park and Recreation Recovery (UPARR) Act federal funding were encumbered, and the need to coordinate with Illinois Department of Natural Resources, the Village of Forest Park, the City of Chicago, and the National Park Service, and to demonstrate all possible planning to minimize harm to the affected properties with SHPO concurrence.

In response, IDOT held a teleconference with DOI on March 29, 2017 in which DOI concurred with IDOT's proposed clarifications and responses to their DEIS comments. In FEIS Appendix O, IDOT responded that further consultation for the additional five properties and one historic district has been completed. IDOT addressed the properties identified as encumbered by DOI: LWCF funds were used for facilities along DesPlaines Avenue in Forest Park not impacted or converted by the I-290 project; UPARR funds were used for a fieldhouse located further north and away from the I-290 project in Columbus Park; and all work near Garfield Park will be performed on existing right-of-way. An Effects Assessment Report was distributed to the consulting parties and the SHPO for review and comment on April 27, 2017, the results of this consultation was

given to the DOI, and coordination will continue to address any questions remaining with regard to possible encumbrance of the parks.

US Army Corps of Engineers (USACE). The USACE stated the following: all alternatives would impact less than 1 acre of Waters of the United States (WOUS); that a Section 404 permit would be needed prior to construction, anticipated to be reviewed under Regional Permit 3; that the project should be designed to comply with permit conditions; and that wetland delineations would need to be updated prior to submitting a permit application.

IDOT addressed USACE's concerns directly in Appendix O of the FEIS and no further coordination was required. In Appendix O, IDOT responded that a Section 404 permit would be obtained prior to commencement of any construction in WOUS; noted their understanding that the project will be processed under Regional Permit 3; that the project will be designed consistent with the conditions of this permit; and that an updated wetland delineation will be prepared and submitted to USACE prior to the Section 404 permit application.

Forest County Potawatomi: The Forest County Potawatomi noted that the DEIS indicated no known archaeological sites within the APE, asked whether an archaeological survey or an archival review had been done, and requested a copy of the survey if one had been done.

IDOT responded in FEIS Appendix O that surveys performed in 2010 and 2015 by the Illinois State Archaeological Survey resulted in finding no archaeological sites, and that a copy of the surveys would be provided to the Forest County Potawatomi. A copy of the survey short report and documentation of consultation with and concurrence from the Illinois SHPO was provided to Forest County Potawatomi on June 8, 2017.

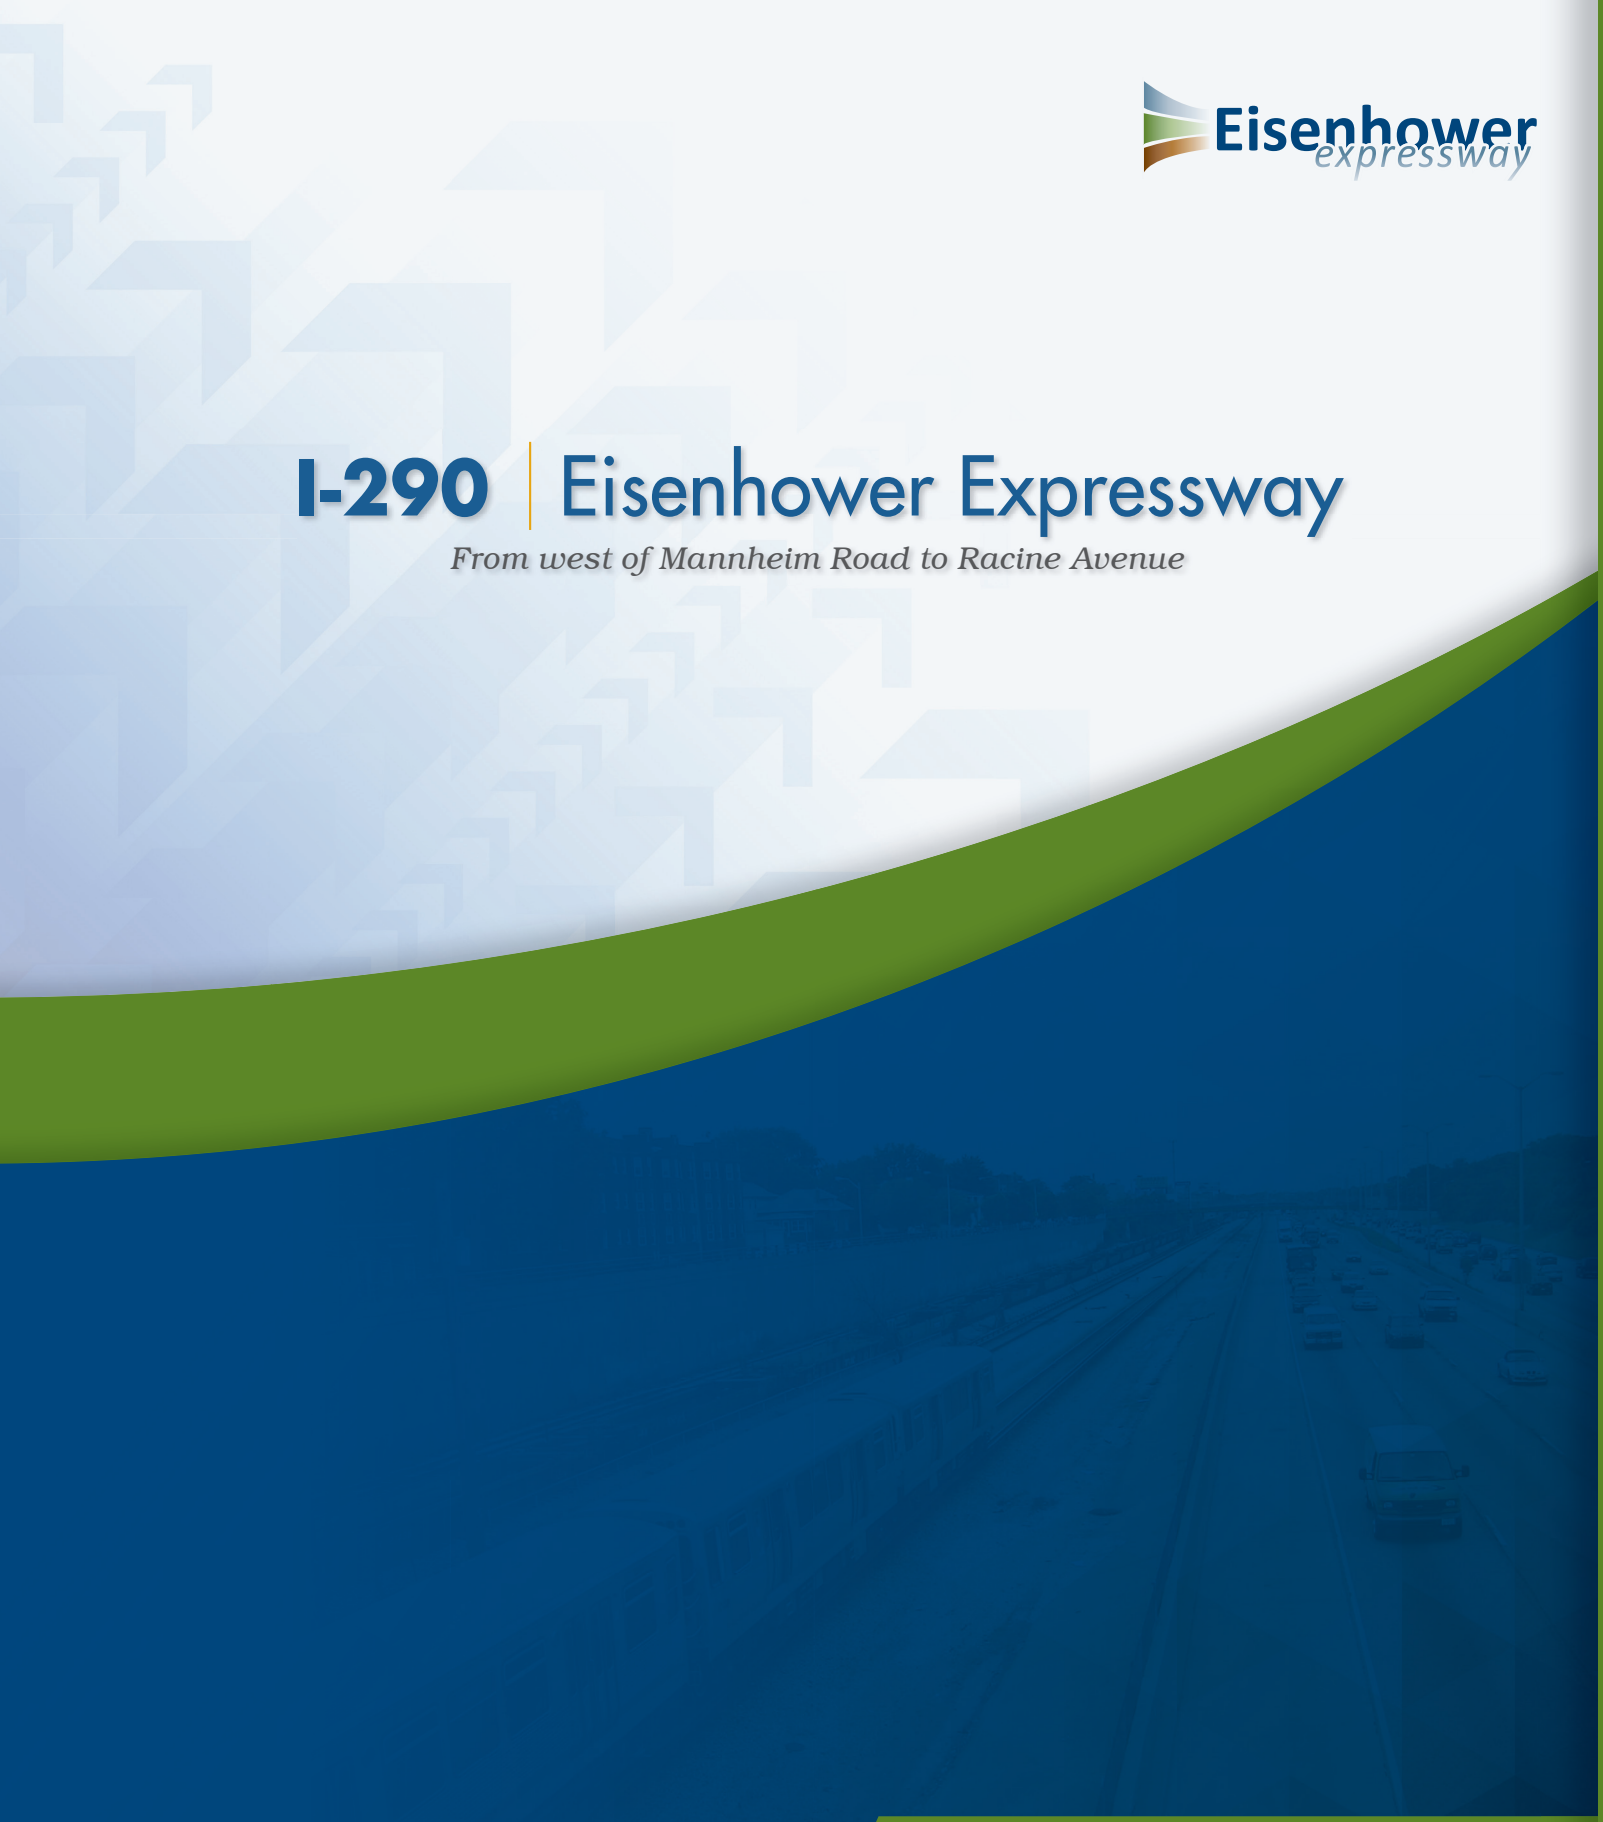
4.5.2 Local Governments

Local governments' formal DEIS comments included the following: comments on design and construction needs and requests for corrections and additions to the FEIS from Metropolitan Water Reclamation District; a request to extend the DEIS comment period, affirming the items agreed to in the Letter of Intent (LOI), and requesting any conflicts with the LOI and the DEIS be resolved in the FEIS from Village of Oak Park; comments on the needs of the overhead bridge and adjacent intersections at Western Avenue, general approval of the improved frontage road drainage, and questions on noise wall maintenance at Harrison Street and Bataan Drive from Cook County Department of Transportation and Highways; and concern for disproportionate impacts from tolling and support of additional project funding from DuPage County. Detailed local government comments are on pages N-14 through N-22 in Appendix N and IDOT responses are on pages O-12 through O-14 in Appendix O.

4.5.3 Public Organizations

Approximately 75 percent of the unique comments from public organizations came from two groups, Citizens for Appropriate Transportation and the Active Transportation Alliance. Citizens for Appropriate Transportation offered several comments on purpose and need of the project, alternatives, impacts, how the alternatives were evaluated, citizen participation, and general comments including proofreading errors. Active Transportation Alliance offered several comments regarding regional planning and the emphasis of highway modes, recommending traffic management strategies rather than lane expansion, and expressing concern that the study had not fully addressed safety, environmental, and traffic issues. Other public organizations offered comments including recommending a Blue Line extension, concern about how lanes are added, recommending a covered expressway rather than noise walls, non-project related comments, recommending lane additions to reduce crashes, recommending lanes not be added, and requesting additional tree planting. Detailed public organization comments are on pages N-23 through N-45 in Appendix N and IDOT responses are on pages O-15 through O-33 in Appendix O.

4.6 Conclusion



CSS and stakeholder outreach were essential components of the I-290 Study process and a primary driver of study progress. Since stakeholder involvement activities for the EIS first began in October 2009, with the initial CAG meeting, a substantial array of stakeholder input has been received, considered, and used to reach a consensus on a preferred alternative and other improvements recommended along Eisenhower Expressway, from west of Mannheim Road to Racine Avenue. Nearly 200 individual community, agency, and other stakeholder meetings have been held to present information, listen to stakeholder concerns and needs, and discuss and refine ideas. The individual meetings were complemented by a series of 22 CAG meetings to provide guidance on project development. As a result of this collective outreach and community involvement, more than 1,700 public comments were received and considered from October 2009 to April 2017. The culmination of this robust stakeholder outreach program has resulted in a project that reflects, to the extent feasible, community and stakeholder values in this Project Corridor.

Comparison of Alternatives

June 2017

Illinois Department of Transportation

U. S. Department of Transportation
Federal Highway Administration

5.0 Comparison of Alternatives Summary

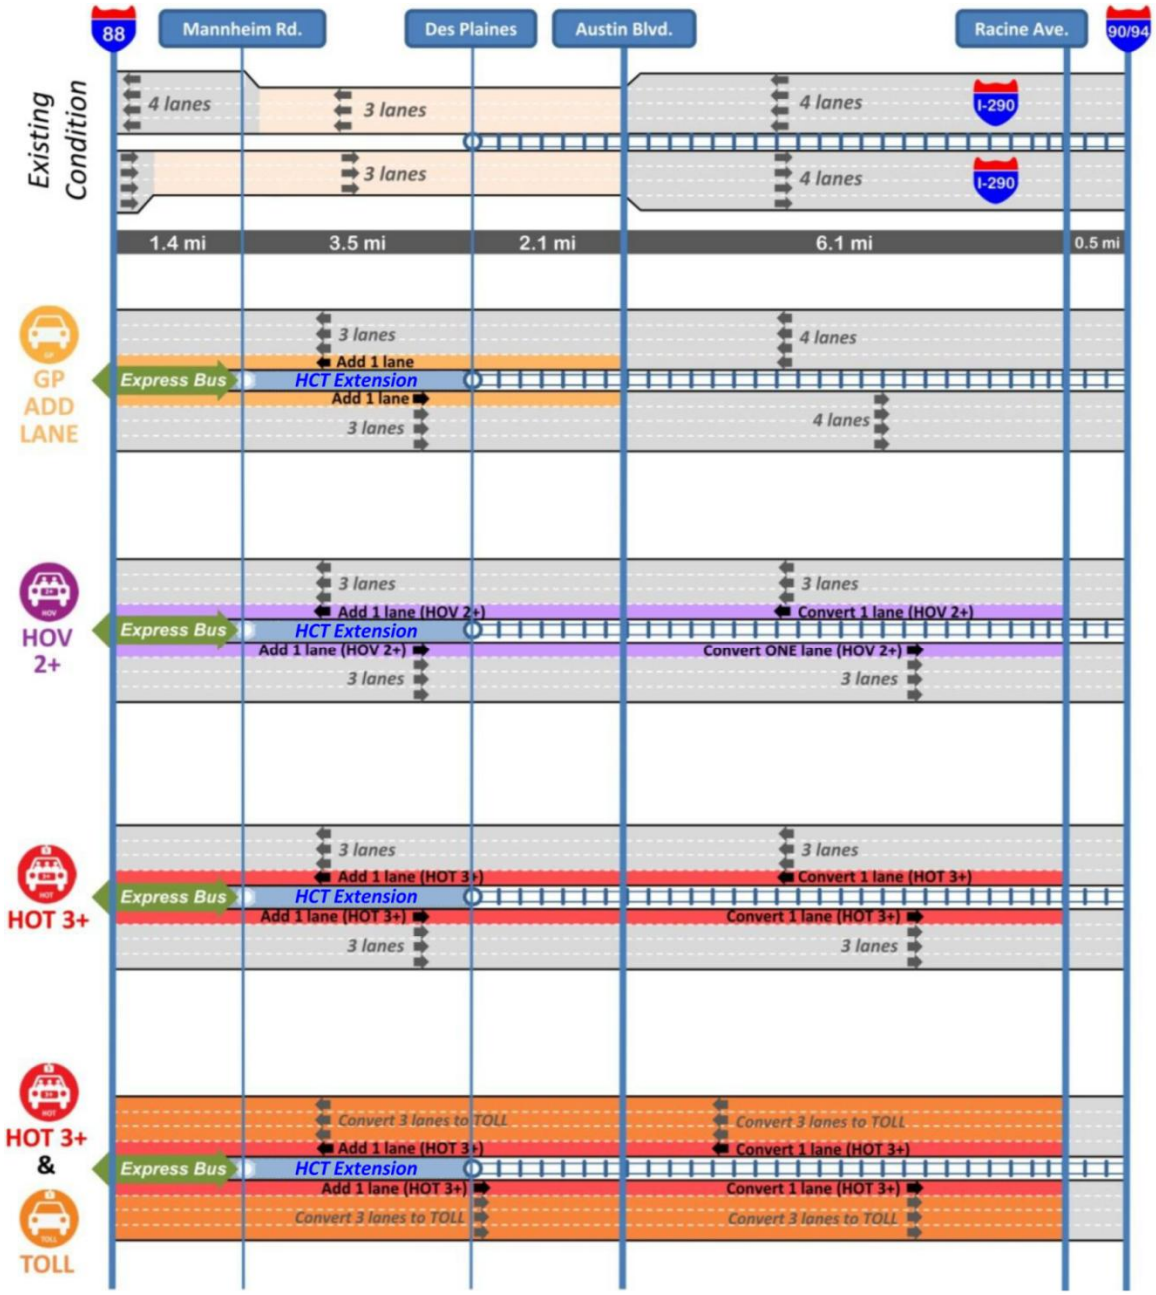
Since the publication of the Draft Environmental Impact Statement (DEIS), the following substantive changes to this section have been made:

- Updated Section 5.3.2 to acknowledge receipt of Officials with Jurisdiction (OWJ) concurrence to *de minimis* impact and Section 4(f) exception findings within Village of Forest Park parklands and Columbus Park;
- Updated Section 5.3.2 and Tables 5-1 and 5-4 to acknowledge FHWA's no adverse effect finding, and SHPO's concurrence thereof, for the project;
- Updated Section 5.4.2 to clarify the Implications for Build Alternatives regarding the use of the Value Pricing Pilot Project (VPPP); and
- Updated Section 5.5.4 to revise the toll rates assumed for the Preferred Alternative.

This section summarizes the results of the alternatives development and analysis contained in Sections 2.0, Alternatives; 3.0, Environmental Resources, Impacts and Mitigation; and 4.0, Public Comments and Agency Coordination. Based on the comparison of socio-economic and environmental impacts, travel performance, and other factors including stakeholder and agency input, the HOT 3+ & EXP and HCT Alternative (also referred to herein as the HOT 3+ Alternative) is the Preferred Alternative.

HCT – High Capacity Transit
A transit mode providing high person throughput. HCT can either use buses in a dedicated traffic lane (bus rapid transit or "BRT") or heavy rail transit (HRT) such as the CTA Blue Line.

5.1 Alternatives Carried Forward



The development and evaluation of the alternatives was an iterative process guided by extensive stakeholder involvement, as described in Section 4.0, Public Comments and Agency Coordination, combined with technical analysis and environmental impact avoidance/minimization efforts using field surveyed resource data and impact modeling. The alternatives development and evaluation process in Section 2.0, Alternatives, concluded with the identification of a range of alternatives to be considered (including a No Build Alternative). The process included three rounds of identification, evaluation, and refinement that considered a wide range of suggested alternatives, single mode alternatives, and combination mode alternatives that resulted in the selection of four build alternatives carried forward for further refinement and analysis in Section 3.0, Environmental Resources, Impacts, and Mitigation. These alternatives carried forward in Section 3.0 are as follows:

- **GP & EXP & HCT** (also referred to herein as GP Lane), consisting of adding one general purpose lane[1] in each direction between 25th Avenue and Austin Boulevard, and includes provisions for Express Bus (EXP) and High Capacity Transit (HCT);
- **HOV 2+ & EXP & HCT** (also referred to herein as HOV 2+), consisting of adding one High Occupancy Vehicle (HOV) 2+ (two or more occupants required for use) lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction west of 25th Avenue and east of Austin Boulevard to HOV use, and provisions for EXP and HCT;
- **HOT 3+ & EXP & HCT** (also referred to herein as HOT 3+), consisting of adding one High Occupancy Toll (HOT) 3+ (three or more occupants per vehicle required for non-tolled use, or one/two occupants per vehicle paying a toll) lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction west of 25th Avenue and east of Austin Boulevard to HOT 3+ use, and provisions for EXP and HCT;
- **HOT 3+ & TOLL & EXP & HCT** (also referred to herein as HOT 3+ & TOLL), consisting of adding one HOT 3+ lane in each direction between 25th Avenue and Austin Boulevard, conversion of one existing general purpose lane in each direction west of 25th Avenue and east of Austin Boulevard to HOT 3+ use, conversion of the remaining general purpose lanes to toll lanes (users of these lanes paying a toll), and provisions for EXP and HCT; and
- The **No Build Alternative** is also carried forward to provide a baseline of comparison of travel benefits, as well as environmental impacts. This alternative consists of planned improvements to existing roadway and transit facilities in the Study Area that are expected to be constructed by the design year (2040) with the exclusion of major improvements to I-290 or the Chicago Transit Authority (CTA) Forest Park Branch. The transportation conditions assumed to exist under the No Build Alternative include the existing transportation network plus major capital projects (excluding major capital projects in the Study Area) currently in the Chicago Metropolitan Agency for Planning (CMAP) 2040 fiscally constrained plan referenced in Section 1.1. The environmental conditions that would exist under the No Build Alternative are generally consistent with the existing conditions as described in Section 3.0, except to the extent that those existing conditions would be affected by other actions (e.g., other transportation or development projects) as described in Section 3.15, Indirect and Cumulative Impacts. The No Build Alternative would not satisfy the project's Purpose and Need.

Figure 5-1 shows a concept for each of the four build alternatives, along with the existing condition.

[1] "General purpose lanes (also referred to as "mixed-use" or "mixed-flow" lanes) are those where use is allowed by all vehicles (except certain small motorized vehicles, bicycles, and pedestrians on limited-access highways), without restriction on number of occupants or imposition of a toll. All lanes on I-290 are currently general purpose.

Figure 5-1. Four Build Alternatives Evaluated in Round 3

The four build alternatives have identical footprints. Therefore, they are very similar to one another; the differences between the alternatives are related to travel performance and social and economic and environmental impacts due to the manner in which traffic would be managed, and the differences in traffic volumes and patterns resulting from this management. Given the location of the project in a developed urban setting, the improvements proposed are almost entirely contained within existing I-290 right-of-way, with the exception of 3.322 acres located near five interchanges or cross roads proposed for reconstruction and 2.650 acres for a 10-foot-wide strip of right-of-way from

the CTA Blue Line. Thus, as was desired by the communities, there are no residential or commercial displacements resulting from the build alternatives. In addition, the Austin Boulevard and Harlem Avenue interchanges would retain their center ramp termini (although converted to right hand on- and off-ramps) in response to community concerns.

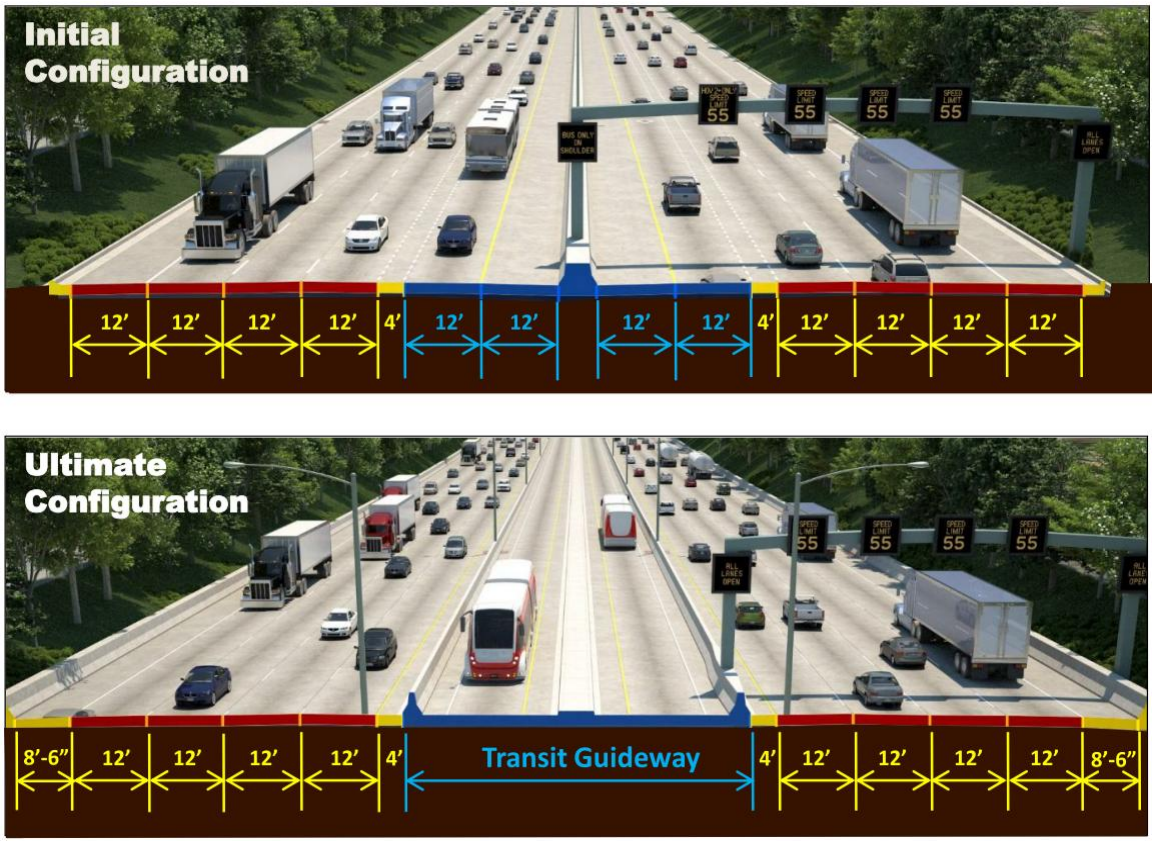
All four build alternatives improve safety for motorists and pedestrians. Primary safety improvements include elimination of the expressway lane drops (westbound at Austin Boulevard and eastbound at 25th Avenue), which would help reduce congestion related rear-end and side-swipe crashes that are prevalent with lane drops. As stated previously, the left-hand ramps at the Austin Boulevard and Harlem Avenue interchanges are proposed to be converted to conventional right-hand ramps, which are consistent with driver expectations and with all other ramps in the corridor. The interchanges and cross roads are designed to modern standards, including improved truck turning radii, improved vehicle storage, wider sidewalks, Americans with Disabilities Act (ADA) ramps, pedestrian plaza areas, modern pedestrian countdown signals, and pedestrian refuge islands in between the ramps at the Austin Boulevard and Harlem Avenue interchanges.

All four build alternatives improve access to transit and nonmotorized travel. This includes wider sidewalks on all cross bridges in the Reconstruction Section, including additional width for sidewalks serving CTA Blue Line stations. Increased pedestrian plaza space for CTA Blue Line station entrances provides space for bicycle parking, bus passengers, and bus passenger shelters. Access to CTA Blue Line stations in the Reconstruction Section would be ADA accessible, which is currently not the case in much of the corridor.

With regard to environmental resources, the four build alternatives have no impacts to wetlands, wildlife, and agricultural resources. The four build alternatives each result in the same 12.94 acre-feet net decrease in floodplain fill volume, and water quality standards would continue to be met. There would be no direct use of adjacent Section 4(f) resources required by the build alternatives except for a *de minimis* impact to 0.031 acre of public parkland in the Village of Forest Park, a temporary use of 0.137 acre of parkland in the Village of Forest Park and Section 4(f) exception of 2.74 acres at Columbus Park. There are no distinguishing differences between the build alternatives with respect to potential uses of Section 4(f) resources.

Each of the four build alternatives would satisfy the Project Purpose and Need. However, the extent of impacts, the level of overall travel performance, and the economic benefits vary for each of these alternatives. Since the physical footprint on the land by each of the build alternatives is primarily confined within the existing I-290 right-of-way and is the same for the four build alternatives, environmental mitigation is proposed to be identical for each of the alternatives.

As stated in Section 3.12.3, FHWA issues a *de minimis* impact finding for Veterans Park, the Dog Park, and the Roos Property based on the minimization measures proposed and concurrence received from the Officials with Jurisdiction (OWJs) that there is not an



adverse effect to the features, attributes, and activities that make the properties eligible for 4(f) protection. The project would not adversely impact the long-term use, function, or development of these parks.

Regarding Columbus Park, the Chicago Park District and State Historic Preservation Officer (SHPO) concurred that the scope of the improvements proposed constitute a Section 4(f) exception under 23 CFR 774.13(g), would not adversely impact the park and, in fact, would provide additional opportunities to enhance the historic integrity of the park, while providing additional benefits to park visitors.

5.1.1 Accommodation for High Capacity Transit

As their names imply, each of the four build alternatives accommodates improvements to the existing HCT, the CTA Blue Line where it exists today, and provides for a westward expansion of HCT to Mannheim Road. West of the CTA Forest Park Terminal, an extension of HCT can be accommodated in the median of the expressway. Staged construction of I-290 is assumed such that the reconstructed expressway and overhead bridges would be configured to accommodate a subsequent HCT extension within the median without the need to reconstruct the expressway or overhead bridges. Figure 5-2 illustrates this staged approach, which utilizes an expressway typical section configured for future conversion of the inside lanes to HCT.

Figure 5-2. Convertible Expressway Section – Initial and Ultimate Configuration

In the initial configuration, EXP bus service would be accommodated along the expressway either in the inside managed lanes or along the inside shoulders. The accommodation of the EXP and HCT modes is similar between build alternatives and is not a distinguishing factor.

5.1.2 Comparison Matrix of Alternatives

Identification of the Preferred Alternative is based on a comparison of key factors with respect to travel performance, socio-economic, and environmental impacts for the alternatives carried forward, as well as stakeholder and agency input, which is summarized below. A comparative table of overall performance, impacts, and costs/revenues is presented in Table 5-1. For clarity, table values in red in the Transportation Performance (2040), Social /Economic, Air Quality, Traffic Noise, and Natural Resources-Floodplains sections represent reduced performance or greater impacts than the No Build Alternative, and table values in green in these sections represent better performance or lesser impacts than the No Build Alternative.

Table 5-1. Comparison Matrix of Alternatives

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
1.0	**Transportation Performance (2040)**						
1.1	Regional vehicle miles traveled (VMT) (miles)	Quantitative	201,187,710	+151,380	+72,492	+52,211	+33,774
1.2	Regional vehicle hours traveled (VHT) (hours)	Quantitative	8,067,709	-9,840	-9,773	-16,161	-17,300
1.3	I-290 travel time (Min) (GP/ML)	Quantitative	30.7 / NA	21.2 / NA	23.2 / 13.7	23.0 / 13.5	14.8 / 12.6

* Per policy, noise impacts are only identified for the build condition.

** Increased concentration and loading for any build alternative would be offset with best management practices (BMP) and deicing practices.

5.2 Performance Comparison

This section provides a summary comparison of travel performance characteristics for the four build alternatives, as well as a baseline comparison with the No Build Alternative. Notable travel performance advantages and disadvantages of each build alternative, compared to the No Build Alternative and to each other, are summarized below. Performance projections that are poorer than the No Build Alternative are shown in red and performance in Table 5-2.

- GP Lane: The primary performance advantage of this alternative is that it would result in the greatest reduction in arterial vehicle miles traveled (VMT) and vehicle hours traveled (VHT) in the Study Area. Its performance disadvantages relative to the other build alternatives are that it would result in the highest increase in regional VMT, second lowest decrease in regional VHT, lowest person throughput, lowest increase in job accessibility, and second lowest reduction in crashes.
- HOV 2+: This alternative's performance advantages are that it would result in the highest person throughput, second highest increase in number of jobs accessible, and highest reduction in predicted crashes. Its performance disadvantages relative to the other build alternatives are that it would result in the second highest increase in regional VMT, lowest decrease in regional VHT, slowest general purpose lane travel time, second highest increase in arterial VMT, and lowest increase in east-west transit trips.
- HOT 3+: This alternative's performance advantages are that it would result in the second lowest increase in regional VMT, second highest reduction in regional VHT, second highest reduction in arterial VMT and VHT, second highest person throughput, highest increase in job accessibility, second highest reduction in crashes, and second highest increase in transit trips. Its performance disadvantage relative to the other build alternatives is that it would result in the second-to-worst general purpose lane travel time compared to the other build alternatives, but is still an improvement compared to the No Build Alternative.
- HOT 3+ & TOLL: This alternative's performance advantages are that it would result in the lowest increase in regional VMT, its highest reduction in regional VHT, fastest travel time, and greatest inducement of east-west transit trips. Its performance disadvantages relative to the other build alternatives are that it would result in the highest increase in arterial VMT (diverting the most traffic to the arterial network), highest arterial VHT, second lowest person throughput, and lowest reduction in crashes.

Regional VMT
Regional VMT is vehicle miles traveled across the entire Chicago region.

It is noted that all of the build alternatives would increase regional VMT higher than the No Build Alternative; however, this represents a regional increase of less than one tenth of a percent in regional miles traveled for each alternative. For all other

Table 5-2. Transportation Performance Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
1.0	**Transportation Performance (2040)**						
1.1	Regional VMT (miles)	Quantitative	201,187,710	+151,380	+72,492	+52,211	+33,774
1.2	Regional VHT (hours)	Quantitative	8,067,709	-9,840	-9,773	-16,161	-17,300
1.3	I-290 travel time (Min) (GP/ML)	Quantitative	30.7 / NA	21.2 / NA	23.2 / 13.7	23.0 /13.5	14.8 / 12.6
1.4	Study area arterial VMT (miles)	Quantitative	4,294,011	-24,560	+6,944	-8,853	+147,834
1.5	Study area arterial VHT (Hours)	Quantitative	255,282	-1,996	-967	-1,643	+6,778
1.6	Person throughput	Quantitative	459,122	+25,247	+31,871	+28,604	+25,294
1.7	Job accessibility	Quantitative	5,151,539	+105,053	+364,948	+397,660	+326,499
1.8	Overall safety (crashes per million person miles per year)	Quantitative	0.287	-4.86%	-6.44%	-6.21%	-4.65%
1.9	East-west transit trips	Quantitative	76,950	+4,375	+2,150	+4,425	+8,425

performance characteristics, the four build alternatives generally perform better than the No Build Alternative, with the HOV 2+ and HOT 3+ & TOLL alternatives performing slightly worse than the No Build Alternative in one or more measures related to arterial traffic performance.

It is also noted that the HOT 3+ Alternative performs near the top in nearly all categories and does not have a single "worst in category" ranking as is the case for each of the other build alternatives.

5.3 Social/Economic and Environmental Impacts Comparison

This section provides a summary comparison of social/economic and environmental impacts. There are few social/economic or environmental impacts that could be described as "distinguishing" among the build alternatives, even where there are slight differences in impacts. In the case of air quality, the differences in impacts between the No Build Alternative and the build alternatives are generally less than 1 percent (better or worse) for each of the pollutants studied. In the case of noise impacts, the number of receptors that would be approaching, meeting or exceeding the Noise Abatement Criteria (NAC) varies slightly between the four build alternatives due to traffic volume variations; this indicates that traffic noise mitigation for the four alternatives would be similar and would not be a major differentiator between the alternatives. Noise barrier locations and heights are evaluated for the Preferred Alternative, at which time a 'viewpoints solicitation' is conducted. This solicitation is required by Illinois Department of Transportation (IDOT) noise policy and requires that stakeholders who are benefited by a proposed noise wall are provided an opportunity to vote on whether they would rather have the barriers. The results of the voting determine if the proposed noise walls are implemented.

5.3.1 Social/Economic Impacts (including Environmental Justice)

Environmental Justice: Within each build alternative, there are no apparent accessibility differences in travel times between the environmental justice (EJ) and non-EJ communities; average travel times to regional employment centers are reduced with the four build alternatives from the EJ communities of East Garfield Park, West Garfield Park, North Maywood, South Maywood, and Bellwood, as well as the non-EJ communities of Oak Park and Forest Park (Items 2.02 and 2.03 of Table 5-3).

Table 5-3. Social/Economic Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL

[2] NCHRP 08-36, Task 103 - Mining Recovery Act Data for Opportunities to Improve the State of Practice for Overall Economic Impact Analysis of Transportation Investments, Cambridge Systematics & Economic Development Research Group, 2012. 10.55 jobs/$1M construction cost in 2010 adjusted to 9.82 jobs/$1M construction cost for 2015 using CPI. 2015 cost estimates used as basis for estimating direct construction jobs.

Table 5-3. Social/Economic Impact Comparison (continued)

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
2.10	Consistency with local and regional plans	Qualitative	No Effect	CMAP includes capacity improvements in the Project Corridor in its *Go To 2040* plan and classifies improvements to the I-290 Eisenhower Expressway as one of the regions 'priority projects.' The local comprehensive plans for Oak Park, Maywood, Broadview, Hillside, and Bellwood all express a desire to improve access to I-290.			
2.11	Community cohesion	Qualitative	No Effect	Improvements to roadways and pedestrian facilities crossing the highway would improve community cohesion.			
2.12	Land use changes	Quantitative	No Effect	No major land use changes are expected as a result of the project, which mostly stays within the existing right-of-way.			
2.13	Right-of-way acquisition	Quantitative	0	5.972 acres of right-of-way (ownership) and permanent easement.			

All of the build alternatives have at least one non-toll travel option. Non-tolled general purpose lanes within the build alternatives offer lower overall travel time than those within the No Build Alternative condition. However, the HOT 3+ & TOLL Alternative is the most restrictive alternative for low-income populations, with a requirement of three or more occupants to qualify for toll-free access to the managed HOT 3+ lane, as all the general purpose lanes are tolled. The other alternatives offer a minimum of three non-tolled lanes in each direction and a fourth lane that can also be accessed with no toll (subject to minimum passenger requirements for the HOV 2+ and HOT 3+ alternatives).

Traffic diversion to and from arterial streets is most identifiable for the HOT 3+ & TOLL Alternative. This alternative is projected to result in an overall worsening of arterial traffic in the Project Corridor (with projected 2040 increases of 147,834 VMT and 6,778 VHT on Study Area arterial roads as compared to the No Build Alternative – Table 5-2), and would have a negative impact to the adjacent EJ communities since these are their neighborhood streets. Except for HOV 2+'s relatively higher arterial VMT, compared to the 2040 No Build and HOT 3+ & TOLL alternatives, the remaining three build alternatives show improved arterial operations which demonstrates a travel benefit to the adjacent EJ communities.

Four out of the five CTA Blue Line stations in the Reconstruction Section of the Project Corridor serve EJ communities. Each of the build alternatives would improve access to these four CTA stations, improve bicycle and pedestrian facilities, and enhance transportation options and connectivity for EJ communities. The HOV 2+, HOT 3+, and HOT 3+ & TOLL alternatives offer the best accommodations for express bus service in a managed lane along I-290, which provides additional transportation options for EJ communities. The HOT 3+ & TOLL Alternative, which tolls all four lanes of I-290 in each direction, results in a greater auto diversion to transit; however, the benefits of the relatively minor increase in transit ridership is countered by the more restrictive conditions to low-income populations as stated above, including increases in regional and arterial VMT. The provision of a 'carpool lane' in the HOV 2+ Alternative provides more competition to transit, resulting in a relatively smaller increase in transit ridership compared to other build alternatives; however, the managed lane alternatives include free access for carpooling which offers a benefit to the EJ communities as they provide an additional low-cost travel option.

The most safety benefits to EJ populations are associated with the HOV 2+ and HOT 3+ alternatives that result in very similar overall safety improvements for arterials, expressway, and transit, while not disproportionally favoring non-EJ populations. Compared to the No Build Alternative, the HOT 3+ & TOLL Alternative may disproportionately affect EJ populations should low-income users favor the arterial network (which has an inherently higher crash potential than limited access roads like I-290) to avoid the tolls imposed along the expressway.

Other Social/Economic Impacts: No business or residential displacements would be required for any of the build alternatives; furthermore, all build alternatives are projected to be compatible with local and regional planning, would improve community cohesion, and are not anticipated to result in major land use plan changes in this fully developed corridor (Table 5-3).

5.3.2 Section 4(f) Resources

A comparison of Section 4(f) resource impacts on historic properties and parks, recreational areas, and wildlife/waterfowl refuges is shown in Table 5-4.

Historic Properties: Based on FHWA's Section 106 effect finding (Section 3.2.3.1), the Preferred Alternative would have no effect to six historic properties and no adverse effect to 17 historic properties in the APE. No direct physical impacts to 22 of the 23 historic properties would occur as a result of the Preferred Alternative because the proposed improvements generally fit within existing right-of-way, outside of NRHP boundaries. Project activity is proposed within the NHL boundary of Columbus Park, but the Section 4(f) exception and proposed improvements would have no adverse effect to the property. Additionally, no indirect effects to historic properties would occur because traffic noise and visual project components would not adversely diminish their integrity or alter the characteristics qualifying these properties for the NRHP. Therefore, FHWA made an overall project finding of no adverse effect.

Table 5-4. Section 4(f) Resources Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
3.0	Historic Resources						
3.1	Historic properties impacted	Qualitative	No Historic Properties Affected	No effect to 6 historic properties and no adverse effect to 17 historic properties in the APE. No direct physical impacts to 22 of the 23 historic properties would occur; a temporary easement and proposed improvements would be located in the NHL boundary of Columbus Park, but they would have no adverse effect to the property. No indirect effects to historic properties would occur. FHWA made a no adverse effect finding to built historic properties and the SHPO concurred on May 25, 2017.			
3.2	Parks, Recreational Areas, Wildlife/Waterfowl Refuges						
3.3	Parkland impacts	Quantitative & Qualitative	No impacts to parks	Improved access to 51 parks and recreation areas along the Project Corridor by new or improved pedestrian and bicycle routes. Pedestrian access improvements require the permanent use of 0.031 acre and the temporary use of 0.137 acre from Veterans Park, the Dog Park, and the Roos Property in the Village of Forest Park, at the request of the Village. Section 4(f) exception of 2.74 acres at Columbus Park.			
3.4	Section 4(f)	Quantitative & Qualitative	No impacts to parks	*De minimis* impact, including 0.031 acre of direct impacts to parks maintained by the Village of Forest Park to accommodate widened and new sidewalks. No other direct, temporary, or constructive use of publicly owned parks and recreational areas is required by the four build alternatives. The enhancement of 2.74 acres at Columbus Park is an exception to Section 4(f) under 23 CFR 774.13(g).			

Parks, Recreational Areas, Wildlife/Waterfowl Refuges: No Section 4(f) use of historic properties, parks, wildlife/waterfowl refuges, recreation areas, would occur except for 0.031 acre of direct use and 0.137 acre of temporary use to parks within the Village of Forest Park: Veterans Park, the Dog Park; and the Recreational Center (Roos Property). The areas are proposed to accommodate widened sidewalks and provide access to the

shared-use path proposed from the Illinois Prairie Path to Central Avenue. Formal written concurrence with these proposed uses was received from the Village, and the Park District of Forest Park. As stated in Section 3.12.3, FHWA issues a *de minimis* impact finding for the three parks based on the minimization measures proposed and written concurrence from the Officials with Jurisdiction (OWJs) that there is not an adverse effect to the features, attributes, and activities that make the properties eligible for 4(f) protection.

Consultation with the Chicago Park District was initiated regarding the extension of the proposed shared-use path through Columbus Park, along with the placement of small berms and trees. October 15, 2015, correspondence from the Chicago Park District indicated no adverse impact and a potential enhancement for the park. In addition, formal consultation with the SHPO confirmed (May 25, 2017) that these improvements, as a National Historic Landmark (NHL), would not result in an adverse effect finding. Formal written concurrence that these improvements met the requirements of 23 CFR 774.13(g) was also received from the Chicago Park District (June 19, 2017) and SHPO (May 26, 2017), and Federal Highway Administration (FHWA) determines this activity to be solely for the purpose of enhancing an activity, feature, or attribute that qualifies the property for Section 4(f) protection, avoiding any Section 4(f) use of Columbus Park.

5.3.3 Visual Resources

From the perspective of the expressway user, the alternatives would alter the visual character due to full reconstruction and replacement of existing bridges, retaining walls, interchange/ramps that would include some new retaining walls, and aesthetic treatments. Because the proposed design for the four build alternatives is the same, effects to visual resources from the expressway is the same for the build alternatives and is not a differentiator (Table 5-5).

Table 5-5. Visual Resources Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
4.0	Visual Resources						
4.1	Visual Impacts/ Benefits	Qualitative	No Effect	Proposed transportation improvements with respect to the visual environment are the same for all build alternatives. Aesthetic treatments will be evaluated for the Preferred Alternative. 46 of 63 eligible noise barriers were favored by "benefited receptor" stakeholders and are likely to be built, pending future project coordination.			

From the local street perspective, because the design of the alternatives is the same, the effect to visual resources is the same for the four build alternatives and is not a differentiator.

Noise walls would also have an effect on visual character from the expressway and local perspective. All four build alternatives have similar noise impacts and would result in similar noise wall locations and heights; therefore, noise walls are not a differentiator for visual impacts. Location and height of proposed noise barriers are evaluated for the Preferred Alternative, and implementation of any noise barrier is determined through the noise wall solicitation process where benefited residents vote for or against a wall installation (Section 5.4.6). Change to visual character with respect to noise walls is a factor that is considered by the voters.

5.3.4 Air Quality

For volatile organic compounds (VOC), nitrogen oxide (NO_X), carbon monoxide (CO), and fine particulate matter ($PM_{2.5}$), the GP Lane Alternative is projected to show a slight increase in these air pollutants over the No Build condition, while the other three build alternatives would show no change or a slight decrease in these pollutants (Table 5-6). All build alternatives, including the GP Lane Alternative, would show a slight decrease in PM_{10} compared to the No Build Alternative condition. For greenhouse gas (GHG) emissions, the GP Lane and HOV 2+ alternatives exhibit a slight increase compared to the No Build Alternative condition. Overall, the build alternatives are expected to show minor changes (generally less than one percent better or worse) in regional pollutants, GHG emissions, and mobile source air toxics (MSATs) compared to the No Build Alternative, and no local impacts are currently identified. As such, no mitigation is proposed for operational impacts with any of the build alternatives.

Table 5-6. Air Quality Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternative			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
	Pollutant Burden (annual burden – tons)[1]						
5.1	VOC (Hydrocarbon)	Quantitative	1,270	+0.10%	-0.01%	-0.14%	-0.02%
5.2	NO_X	Quantitative	2,776	+0.21%	-0.12%	-0.07%	-0.60%
5.3	CO	Quantitative	23,708	+0.73%	-0.51%	-0.34%	-0.35%
5.4	PM_{10}	Quantitative	1,813	-0.06%	-0.03%	-0.31%	-0.43%
5.5	$PM_{2.5}$	Quantitative	326	+0.09%	-0.13%	-0.30%	-0.50%
	Greenhouse Gas Emissions (annual burden – million tons)[1]						
5.5	CO_2e	Quantitative	10.517	+0.24%	+0.03%	-0.01%	-0.10%
	MSAT (annual tons)[1]						
5.6	Acrolein	Quantitative	1.17	-0.08%	-0.07%	-0.17%	-0.62%
5.7	Benzene	Quantitative	16.55	+0.30%	-0.04%	-0.08%	+0.05%

[1] Provided as sensitivity test for informational purposes; not intended for Preferred Alternative selection.

5.3.5 Special Waste

There are 495 Recognized Environmental Condition (REC) sites affected by each of the build alternatives, with 13 REC sites within or directly adjacent to the proposed right-of-way acquisition (Section 3.11.2 and 3.11.3); therefore, there are no differentiating impacts among them (Table 5-7).

Table 5-7. Special Waste Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternative			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
7.0	**Special Waste**						
7.1	REC Sites	Quantitative	0	495 sites within Project Corridor; 13 sites within or directly adjacent to the proposed right-of-way acquisition.			

5.3.6 Natural Environment

There are no differentiating impacts to the natural environment among the build alternatives (Table 5-8). An improvement in floodplain storage capacity of 12.94 acre-feet is projected for each of the build alternatives (Section 3.9.2.1).

5.3.7 Traffic Noise

A traffic noise analysis using the FHWA Traffic Noise Model (TNM) was performed for the No Build Alternative and four build alternatives to evaluate the number of receptors that would be over the NAC. Two hundred eighty-eight (288) individual representative receptors were identified and evaluated (Table 5-9).

In the No Build condition, 79 percent of the studied receptors would approach, meet or exceed the NAC criteria, which indicates that most of the Study Area is already experiencing an adverse noise effect. For the build alternatives, the number of receptors approaching, meeting or exceeding the NAC is similar, varying between -7 and +3 receptors compared to the No Build Alternative, and is not considered to be a major differentiator between the build alternatives.

As described in Section 3.4, noise impacts for the four build alternatives are similar and would result in similar size and locations of walls needed for noise mitigation.

Table 5-8. Natural Environment Impact Comparison

	Resource	Analysis Level	No Build Alternative	Build Alternatives			
				GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
8.0	**Natural Environment**						
8.1	Wildlife (number of species impacted)	Quantitative & Qualitative	0	0			
8.2	Wetlands (acres)	Quantitative	0	0			
8.3	Floodplains, volume change from existing (acre-feet)	Quantitative	0	-12.94 acre-feet, normal to 100-year flood elevation (overall flood storage capacity increased)			
8.4	Water Quality – Are Water Quality Standards Met (chlorides, metals, and TSS)? (yes/no)*						
	Salt Creek	Quantitative & Qualitative	Yes	Yes			
	Des Plaines River	Quantitative & Qualitative	Yes	Yes			
	South Branch of Chicago River	Quantitative & Qualitative	Yes	Yes			

* Increased concentration and loading for any build alternative would be offset with BMP and deicing practices.

Table 5-9. Traffic Noise Impact Summary Table

	No Build Alternative	Build Alternatives			
		GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
Total Receptors	288	288	288	288	288
Receptors approaching, meeting or exceeding the NAC	227	230	228	229	220
% of Receptors over NAC	79%	80%	79%	80%	76%

5.4 Other Considerations

This section outlines the implementation considerations of the project, such as policy changes needed relative to tolling and pricing policy, construction staging, and funding. Refer to Section 3.14, Construction Impacts, for a comprehensive discussion on construction impacts, including staging.

5.4.1 Tolling Revenues

A factor in favor of the HOT 3+ and HOT 3+ & TOLL alternatives is their ability to provide revenue for initial construction and/or maintenance and operation of the improved I-290. Projections show that the HOT 3+ Alternative may generate $20 million (2014 $) annually in the year 2040, and the HOT 3+ & TOLL Alternative may generate $100 million (2014 $) annually in the year 2040. It should be noted that actual toll rates for operation have not been determined, and toll revenue would vary depending on toll rate assumptions used.

5.4.2 Tolling and Pricing Policy and Strategies

Tolling and pricing strategies (includes a fixed-price toll or varying the price of a toll based on the time of day or traffic volume) are increasingly emerging as useful tools to finance projects, manage congestion, and facilitate the creation of public-private partnerships (P3). However, all tolling and pricing of Federal-Aid highway system facilities, which includes any facility that previously used Federal-Aid funds, requires legal authority from the federal government, through the US Department of Transportation (USDOT).

Tolling and pricing programs and provisions are available under Title 23 of the United States Code (23 USC), Fixing America's Surface Transportation (FAST) Act, the 5-year federal transportation reauthorization act signed into law in December 2015.

- **Title 23 of the US Code, Sections 129 and 301:** Generally prohibits the imposition of tolls on facilities that have been constructed using federal funds.

- Over time, several exceptions have been passed through special programs and provisions, including:
  - **Section 129:** Allows tolls on new facilities or new lanes on interstate and non-interstate highways, bridges, and tunnels. Tolling revenue may be used for debt service, private investment, operations, maintenance, P3 payments, and other Title 23 eligible uses. There are no performance requirements, and audits must be submitted annually.
  - **Section 166:** Allows tolls on single occupancy vehicles (SOVs) on HOV lanes on interstate and non-interstate highways, bridges, and tunnels. Tolling revenue may be used for debt service, private investment, operations, maintenance, P3 payments, and other Title 23 eligible uses. Performance requirements include operational performance, enforcement, automatic toll collection, and tolls varied to match demand. Audits must be submitted annually.
  - **Value Pricing Pilot Program (VPPP):** Allows value pricing on interstate and non-interstate highways, bridges, and tunnels. Tolling revenue may be used for debt service, private investment, operations, maintenance, project implementation costs, mitigation measures for low-income users, and other Title 23 eligible uses. Performance requirements include monitoring effects on driver behavior, traffic volume, transit ridership, air quality, and availability of funds for transportation programs. Audits must be submitted annually, and a toll agreement is required. There are 15 program slots authorized by Congress, and they are currently encumbered. Illinois currently has a program slot, and each state can have multiple projects.
  - **Interstate System Reconstruction and Rehabilitation Pilot Program:** Allows tolling on interstate highways, bridges, and tunnels being reconstructed or rehabilitated. Tolling revenue may be used for debt service, private investment, operations, and maintenance. There are no performance requirements, audits must be submitted annually, and toll agreement is required. There are three program slots authorized by Congress that are conditionally reserved for the states of Virginia, Missouri, and North Carolina.

Implications for Build Alternatives:

GP Lane and HOV 2+ Alternatives: Since no toll lanes would be proposed under either alternative, federal lane tolling policy would not apply.

HOT 3+ Alternative: The additional new HOT 3+ lane between 25th Avenue and Austin Boulevard on I-290 would be allowed in the HOT 3+ Alternative under current legislation.

West of 25th Avenue and east of Austin Boulevard, conversion of the inner eastbound and westbound general purpose lanes directly to HOT 3+ lanes would be allowed under current legislation through the VPPP. As part of the VPPP, IDOT has the ability to request authority to implement tolling on the inside lane, including a conversion of a general purpose lane in each direction in the eastern portion of the project.

HOT 3+ & TOLL Alternative: The additional new HOT 3+ lane between 25th Avenue and Austin Boulevard on I-290 would be allowed in the HOT 3+ & TOLL Alternative under current legislation.

The conversion of the remaining three existing general purpose lanes in each direction to toll lanes could only occur through the Value Pricing Pilot Program under current federal legislation, or a change in federal legislation granting states additional flexibility in converting non-tolled interstate highway lanes to tolled lanes.

5.4.3 Construction Staging

Construction staging and impacts would be the same for the four build alternatives due to the alternative sharing the same design. Therefore, there are no differences in construction staging and impacts between the four build alternatives.

5.4.4 Construction Cost

A project cost estimate for the build alternatives was developed based on 2015 unit costs escalated to a Year of Expenditure (YOE). All four build alternatives share the same geometric design and construction requirements; therefore, they would have no appreciable differences in construction costs (Table 5-10).

The construction costs would vary based on future design refinements completed during the final phase of project development. The procedure for cost estimating is discussed in Appendix L, Cost Estimating Procedure for Roadway System Alternatives.

Table 5-10. Estimate of Implementation Cost Summary for Build Alternatives

Major Cost Category	Estimated Cost (YOE $)			
	GP Lane	HOV 2+	HOT 3+	HOT 3+ & TOLL
Construction	$1,748 million	$1,748 million	$1,756 million	$1,756 million
Environmental Mitigation	$58 million	$58 million	$58 million	$58 million
Construction Contingency*	$349 million	$349 million	$351 million	$351 million
Design and Engineering Services	$327 million	$327 million	$329 million	$329 million
Design and Engineering Services Contingency	$65 million	$65 million	$66 million	$66 million
Right-of-Way (Permanent)	$6 million	$6 million	$6 million	$6 million
Right-of-Way Contingency	$5 million	$5 million	$5 million	$5 million
Total	$2,558 million	$2,558 million	$2,571 million	$2,571 million

* Includes contingencies for construction, utilities, inflation, and unallocated risks.

All alternatives would incorporate an Intelligent Transportation System (ITS) to monitor and manage traffic in the corridor and are assumed to be the same across each of the alternatives. The ITS is proposed to be a flexible platform that would support, active traffic management (ATM) signs, dynamic message signs (DMS), and standard traffic signs, as well as toll rate signs and toll readers. The incremental cost for adding tolling infrastructure on top of the ITS is estimated at under $13 million (YOE$) for the HOT 3+ and HOT 3+ & TOLL alternatives. This cost represents a small percentage of the overall construction cost and is not considered to be a differentiator.

5.5 Preferred Alternative

This section summarizes the rationale for identifying the HOT 3+ Alternative as the Preferred Alternative.

5.5.1 Achievement of Stakeholder Goals and Objectives

For this project, IDOT implemented its Context Sensitive Solutions (CSS) process for planning and design of major projects. At the outset of the study, through a workshop process with the CAG, goals were identified and a problem statement developed for the project. The initial project goals are listed below, followed by a qualitative description of how these initial goals and problem statement needs were achieved by the build alternatives.

Goal: Improve Mobility (Capacity and Efficiency)

- All four build alternatives add an additional lane in each direction between Austin Boulevard and Mannheim Road, reducing congestion and improving travel times along the corridor.
- The main difference among the four build alternatives is how the additional capacity is "managed."
  - The GP Lane Alternative does not manage the additional capacity as well as the other build alternatives, but provides additional truck capacity, although I-290 has relatively low truck usage (5 to 6 percent of total vehicles are trucks) and improved Study Area arterial performance.
  - The HOV 2+ Alternative begins to manage the fourth lane in each direction, restricting its usage to carpools with two or more occupants and transit buses, providing improved I-290 mainline and managed lane speeds, and improved Study Area arterial performance.
  - The HOT 3+ Alternative manages the fourth lane in each direction by allowing carpools with three or more occupants and transit buses to use the lane for free, and using dynamic pricing to allow other automobiles to use the HOT 3+ lane through tolling. The toll rates would be adjusted based on demand and would ensure average travel speeds of 45 miles per hour (mph) or higher, providing improved travel time reliability and improved Study Area arterial performance.

  - The HOT 3+ & TOLL Alternative would toll all of the lanes on I-290, allowing carpools with three or more occupants and transit buses to use the HOT 3+ lane for free. Regionally, all four build alternative lessen the total time spent traveling on the roadway network, although the HOT 3+ & TOLL Alternative increases Study Area arterial travel times due to diversion of traffic off of I-290 because of tolling all of the lanes.

- All four build alternatives include a 2-mile east-west shared-use path that connects the Illinois Prairie Path to Columbus Park in Chicago. This connection does not currently exist, and it would improve east-west nonmotorized mobility in the Project Corridor and beyond.

Goal: Improve Safety to Motorists, Transit Users, Bicyclists, and Pedestrians

- All four build alternatives would improve overall safety.
- The elimination of the lane drop (westbound at Austin Boulevard and eastbound at 25th Avenue) would reduce congestion and weaving maneuvers that contribute to rear-end and side-swipe crashes at those locations.
- The left-hand ramps at the Austin Boulevard and Harlem Avenue interchanges are relocated to right-hand ramps to help reduce the highest crash rates in the Project Corridor. Compared to the existing left-hand ramps, right-hand ramps are consistent with driver expectations and would improve weaving and sight distance.
- Addition of a mainline auxiliary lane in each direction from 25th Avenue to 1st Avenue would provide improved weaving and safety performance between the ramp and mainline traffic in this section.
- The interchanges in the Reconstruction Section would be redesigned to safer, modern geometric design standards, including improved truck turning radii and improved vehicle storage, as well as modern pedestrian countdown signals and pedestrian refuge islands in between the ramps at the Austin Boulevard and Harlem Avenue interchanges.
- All four build alternatives include the provision of an east-west multi-use path (off-road) that is adjacent to I-290 to improve bicycle and pedestrian safety.
- All four build alternatives include improved, wider sidewalks and pedestrian plazas for transit users at CTA stations.

Goal: Coordinate with Planned Land Uses and Area Developments

- The definition of the four build alternatives was closely coordinated with the Project Corridor municipalities, including accommodating potential future development and addressing access issues to businesses and residential areas.
- The potential for "caps" or decking over I-290, if desired by municipalities to provide additional recreational or commercial activities, can be accommodated where the proposed roadway profile and drainage allows, and subject to cost participation/maintenance, in the Reconstruction Section of the four build

alternatives. The Village of Oak Park has coordinated with IDOT regarding expanded decking opportunities at Oak Park Avenue, East Avenue, Ridgeland Avenue, and Lombard Avenue. Concepts have been developed at these locations that accommodate the proposed I-290 profile; IDOT will continue to work with the Village during Phase II regarding design and funding opportunities.

- Close coordination also occurred with CTA (including the CTA Blue Line Forest Park Branch Feasibility/Vision Study) and Pace, who operate transit services in the Project Corridor, and the Illinois Tollway, whose I-88 Reagan Memorial Tollway ties directly into I-290.

Goal: Facilitate Economic Growth along the Route

- All four build alternatives would result in improved travel times on I-290 and improved interchange operations with reduced vehicle delay. This would result in improved accessibility to/from the Project Corridor, supporting economic growth.
- A full interchange at 25th Avenue is included in the four build alternatives to provide increased accessibility to this north-south corridor, supporting economic growth.
- A full interchange at 1st Avenue with significantly improved operations and reduced congestion is included in the four build alternatives, which would provide increased accessibility to this north-south corridor and local economic zones, supporting economic growth.
- The four alternatives have the potential to provide between $1.6 and $2.9 billion in productivity savings as drivers spend less time traversing the Project Corridor.

Goal: Minimize Impacts to the Surrounding Environment

- The I-290 improvements for the four build alternatives are within the existing I-290 right-of-way, with the exception of 3.322 acres located near five interchanges or cross roads proposed for reconstruction, and 2.650 acres for a 10-foot-wide strip of right-of-way from the CTA Blue Line.
- No displacements would result from the build alternatives.
- EJ communities adjacent to the Project Corridor are addressed by:
  - Access and travel time improvements for the four build alternatives;
  - Managed lanes or express bus on shoulder, which would offer free or inexpensive and reliable travel along the Project Corridor either by riding in a bus in a managed lane or shoulder, or by carpooling;
  - Forecast arterial traffic shows no disproportionate impacts to EJ populations for the Preferred Alternative; the HOT 3+ & TOLL Alternative has some potential impacts, increasing arterial traffic the greatest through EJ communities;
  - Public transit and pedestrian/bicycle improvements would provide benefits to EJ and non-EJ populations;

  - Other environmental factors show no disproportionate impacts to EJ populations; and
  - It is also noted that serving EJ populations with better connectivity, or access, to jobs and essential services, is a primary goal of USDOT's "Ladders of Opportunity" initiative, which provides research and funding for projects that achieve greater connectivity for transportation system users. This initiative defines connectivity, or accessibility, as "the degree to which the transportation system provides access to essential services and other destinations."[3] The public transit and pedestrian/bicycle improvements included in this project would support this initiative.

- Air Quality: The differences in air quality measures for the build alternatives would be minor and indicate minor improvements in comparison to the No Build Alternative, and they are not distinguishing differences.
- Noise: The differences in affected noise receptors among the four build alternatives would be minor; a substantial length of the project is eligible for noise barriers as mitigation under the four build alternatives. Of the 63 eligible noise barriers, 46 were favored by "benefited receptor" stakeholders in the viewpoints solicitation process and are likely to be built, pending future coordination.
- No wetland impacts would result from the four build alternatives.
- Minor floodplain improvements would be provided for all four build alternatives.
- No wildlife impacts would result from the four build alternatives.
- There is a Section 4(f) *de minimis* use at three locations in Forest Park. There is a Section 4(f) exception at Columbus Park in Chicago.
- No direct physical impacts or indirect visual or noise effects to Section 106 properties from the four build alternatives. IDOT developed enhancements to the NHL, Columbus Park, in coordination with the Chicago Park District and the SHPO. These enhancements would have no adverse effect to Columbus Park.

<u>Goal: Address I-290 Infrastructure Condition</u>

- All four build alternatives include full reconstruction from west of Mannheim Road to east of Cicero Avenue, which was originally constructed in the 1950s. The proposed improvements include:
  - Reconstructed pavement;
  - Reconstructed bridges and structures including pedestrian bridges;
  - Additional drainage capacity to accommodate 100-year storm events (instead of 10-year);

[3] USDOT "Ladders of Opportunity" website, https://www.transportation.gov/opportunity (accessed November 15, 2016).

- New efficient lighting; and
- New signage, including ITS features.

Goal: Improve Community Cohesion

- All four build alternatives would improve community cohesion through several features:
  - Wider sidewalks on all cross bridges in the Reconstruction Section;
  - ADA accessibility on all cross-road sidewalks in the Reconstruction Section;
  - The existing pedestrian bridges at Home Avenue and Lavergne Avenue would be wider and ADA accessible;
  - A new east-west shared-use path adjacent to I-290 that would provide an improved connection from the Illinois Prairie Path's eastern terminus (including improvements at Maybrook Drive) to Columbus Park;
  - Maintaining "center" ramp terminals at Austin Boulevard and Harlem Avenue interchanges;
  - The potential for "caps" or decking over I-290, if desired by municipalities to provide additional recreational or commercial activities, can be accommodated in the Reconstruction Section of the four build alternatives; and
  - Opportunities for aesthetic enhancements and features.
- Improvements that address community cohesion also support the USDOT "Ladders of Opportunity" initiative, providing better access across I-290 and to nearby public transit stops.

Goal: Improved Public Transit Access

- Wider sidewalks are proposed on all cross bridges in the Reconstruction Section serving CTA Blue Line stations.
- Pedestrian plaza areas at CTA Blue Line station entrances would provide space for bicycle parking and bus transfer areas, including bus passenger shelters.
- Relocation of bus stops closer to CTA transit stations.
- A new bus pad and shelter area at 1st Avenue and Van Buren Street, near the Maywood Workforce Center.
- Additional and improved crosswalks are provided at the Austin Boulevard, Harlem Avenue, and Cicero Avenue interchanges to improve access to either side of the bridge for transit passengers.
- CTA Blue Line stations in the Reconstruction Section would also be ADA accessible.

Goal: Improve Public Transit Options, including Connectivity and Reverse Commute

- The build alternatives all include additional east-west express bus service on I-290 either on a shoulder or in a managed lane.
- All four build alternatives are designed to accommodate a potential future HCT (Blue Line or BRT) extension from the existing Forest Park Blue Line Station west to Mannheim Road.
- All four build alternatives include enhanced feeder bus service to proposed new HCT extension stations.

Goal: Improve Public Transit Infrastructure Condition

- The CTA Blue Line Forest Park Branch Feasibility/Vision Study, conducted in coordination with the I-290 Study, recommended full reconstruction of the Forest Park Branch to bring its condition to a state of good repair.

Goal: Sustainable Solutions

The FHWA Infrastructure Voluntary Evaluation Sustainability Tool (INVEST) was used to measure the sustainability of the I-290 improvements. Based on a preliminary evaluation of the I-290 Study, it currently achieves a designation of "Bronze" based on current available information and based on the INVEST 1.2 criteria. For the modules used in the INVEST scoring, there is no apparent measure where any of the build alternatives would have more or less difficulty in achieving sustainability; therefore, there is no differentiation between these build alternatives regarding sustainability. For the complete INVEST evaluation of the I-290 Study, refer to Appendix M.

5.5.2 Quantitative Comparison of Alternatives

With all four build alternatives utilizing the same design, the primary variables between the alternatives are related to the varying levels of demand management, ranging from little to no management (GP Lane) to high levels of management (HOT 3+ & TOLL). Travel performance of the build alternatives includes most of the measurable differentiators; however, differentiators in social/economic impacts, environmental impacts, costs, and revenues, where applicable, were considered in a quantitative comparison of alternatives as an aid in selecting a Preferred Alternative. Both rank (ordinal) scoring and ratio scoring were used, as explained below.

Rank (Ordinal) and Ratio Scoring: To objectively evaluate and compare the performance and impacts of the four build alternatives, the Round 3 travel performance results for the four build alternatives were scored two ways:

- Rank (Ordinal) Score: Sixteen (16) performance and impact measures were given a numerical rank of 1 to 4 by alternative, with 1 being the worst and 4 being the best for each of the criteria, and with a maximum possible 64 points for each alternative. This was the same scoring approach as was used in Round 2.

- Ratio Score: The same 16 measures were given a proportional score based on a scale of 0 to 100 by alternative, with 0 being the worst and 100 being the best for each of the criteria, and with a maximum 1,600 possible points for each alternative. Each criterion was scored between 0 and 100 in proportion to the worst performer (assigned 0) and best performer (assigned 100). For example, for the Regional VMT criterion, the worst performance was by the GP Lane Alternative at 151,380 miles (assigned a score of 0) and the best performance was by the HOT 3+ & TOLL Alternative at 33,774 miles (assigned a score of 100). For the purposes of project scoring, the HOT 3+ Alternative, with a Regional VMT performance of 52,211 miles, was assigned a proportional score of 84 for that criterion. The total score of the alternative is the sum of the individual criteria scores.

Environmental Factors: The differences in air quality measures for the build alternatives are generally under 1 percent, better or worse, than the No Build Alternative and are not distinguishing differences. The differences in affected noise receptors among build alternatives are slightly different, at 220 to 230 receptors approaching, meeting or exceeding the NAC criteria. It is noted that a substantial length of the project would be eligible for noise barriers as mitigation under the four build alternatives, and that "benefited receptor" stakeholders participated in a viewpoints solicitation process favoring the building of noise barriers in 46 of 63 potential locations. With the identical project footprints for the four build alternatives, there are virtually no differences between natural resource impacts. 0.031 acre of *de minimis* Section 4(f) permanent use and 0.137 acre temporary use are anticipated for any of the build alternatives. No direct physical impacts or indirect visual or noise effects to Section 106 properties would result from the four build alternatives. The IDOT developed enhancements to the NHL, Columbus Park are common to each of the build alternatives and would have no adverse effect to Columbus Park. Due to the lack of differentiation in environmental impacts for air quality, natural resources, parks and recreation, and historic resources among the build alternatives and in comparison to the 2040 No Build Alternative, the number of noise receptors was the only environmental factor included in the scoring.

The Chicago Park District concurred with pedestrian access improvements, berms, and tree planting at Columbus Park. It is proposed as an enhancement activity planned cooperatively by IDOT and the Chicago Park District. It was not considered a Section 4(f) use and written concurrence was received from the OWJs that it met the requirements of 23 CFR 774.13(g) as an enhancement exception to Section 4(f). Likewise, the SHPO concurred that any such improvements to the park, as a NHL, would not result in an adverse effect finding.

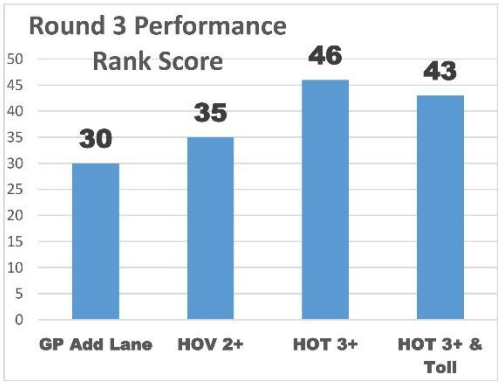
Social/Economic Factors: For the purposes of scoring, travel diversion to local roads, average change in travel time to job for EJ and non-EJ communities, productivity, and construction-related jobs (all measured as changes from the 2040 No Build Alternative) were used as social/economic criteria. As additional context, the HOT 3+ Alternative offers a mixture of travel benefits for the EJ populations. The HOT 3+ Alternative would retain the ability for low-income populations (i.e., EJ populations) to access all lanes without paying a toll. The GP Lane and HOV 2+ alternatives also offer this benefit,

however with some differences. Without a managed lane, the GP Lane Alternative does not provide an opportunity for a reliable trip time on the expressway. Although the HOV 2+ and HOT 3+ & TOLL alternatives offer a reliable trip option for EJ communities, they both result in increased traffic on the local arterials. The HOT 3+ & TOLL may discourage its use by a portion of the low-income communities without some form of tolling relief for low-income populations. The HOT 3+ & TOLL Alternative represents tolling all lanes, so the only free option on I-290 for low-income trips is to use a 3+ person carpool. The tolling of all lanes on I-290 could shift some low-income travelers to use other (non-tolled) routes, including parallel arterials, or 3+ carpools.

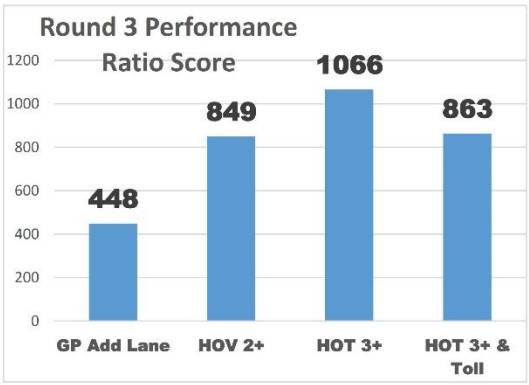
Travel Performance: The HOT 3 + Alternative ranks in the top two for performance for the nine travel measures. The flexibility to manage/control the use of the added capacity, without over managing the general purpose lanes, results in the best balance of regional and local travel performance related to expressway, arterial, and transit travel.

The HOT 3+ & TOLL Alternative offers the best expressway performance, but at the expense of diverting traffic to the local arterials due to diversions by motorists avoiding tolls on I-290. This alternative also results in the lowest safety performance, primarily due to its high diversion of traffic from the expressway to arterial streets, which generally have higher crash rates than expressways. This alternative limits toll-free access for EJ communities to persons in 3+ carpools.

The HOV 2+ Alternative would offer similar benefits as the HOT 3+ Alternative, but to a lesser degree overall. This is due to its inability to fully utilize the capacity of an HOV 2+ lane (only 2+ carpoolers can use it) and does not offer a reliable trip time option to non-HOV users. This alternative also results in the fewest public transit trips among the build alternatives due to the attractiveness of the HOV 2+ lanes to users who might otherwise use transit. HOV 2+ scores in the bottom two for six of the nine measures.



The GP Lane Alternative would offer the greatest local arterial improvement, but at the expense of expressway and regional travel, and job accessibility. This alternative is the lowest performer for four measures and is the worst or second-worst performer for all but two measures. Lacking a managed lane, the GP Lane Alternative also does not offer a reliable travel time option on the expressway.



Of the four build alternatives, the HOT 3+ Alternative demonstrates the best overall travel performance with best or second-best performance scores for all performance criteria (Table 5-11).

The HOT 3+ Alternative scores highest in both rank and ratio scoring, with 46 out of 64 possible points by rank (ordinal) scoring and 1,066 out of 1,600 possible points by ratio scoring.

Table 5-11. Rank and Ratio Scoring Comparison of Build Alternatives

#	Round 3 DEIS Performance Measure	Unit	No-Build	GP Add Lane	HOV 2+	HOT 3+	HOT 3+ & Toll
1.1	Regional vehicle miles traveled (VMT)	miles	201,187,710	151,380	72,492	52,211	33,774
1.2	Regional vehicle hours traveled (VHT)	hours	8,067,709	-9,840	-9,773	-16,161	-17,300
1.3	I-290 Travel Time (GP Lane / Managed Lane)		30.7/NA	21.2/NA	23.2/13.7	23/13.5	14.8/12.6
1.4	Study Area Arterial VMT	miles	4,294,011	-24,560	6,944	-8,853	147,834
1.5	Study Area Arterial VHT	hours	255,282	-1,996	-967	-1,643	6,778
1.6	Person Throughput	persons	459,122	25,247	31,871	28,604	25,294
1.7	Job Accessibility	# of jobs	5,151,539	105,053	364,948	397,660	326,499

5.5.3 Implementation Flexibility

A Congestion Pricing Pilot Program was established by the US Congress in 1991. In 1998, it was subsequently renamed the Value Pricing Pilot Program (VPPP) under Section 1216 (a) of TEA-21, and continued under subsequent Federal Surface Transportation Bills including the current FAST Act. The VPPP is intended as a mechanism to address congestion through application of congestion pricing strategies and to report on the magnitude of the impact of such strategies on driver behavior, traffic volumes, transit ridership, air quality and availability of funds for transportation programs. There are 12 state-led programs and 2 city-led programs participating in the VPPP, including the state of Illinois. As part of the VPPP, IDOT has the ability to request

authority to implement tolling on the inside lane, including a conversion of a general purpose lane in each direction in the eastern portion of the project.

5.5.4 Refinements to HOT 3+ Included in the Preferred Alternative

There are a small number of refinements to the HOT 3+ Alternative that are included in the Preferred Alternative. These include the following:

- A change from five designated managed lane access points, permitting drivers to move to and from the general purpose lanes to the managed lanes at restricted points at 25th Avenue, 17th Avenue, 1st Avenue, Central Avenue, and Cicero Avenue during the Round 3 evaluations – to a "continuous access" configuration, allowing drivers to cross into or out of the managed lanes at any point. This change created a slight change in the way traffic utilized the traffic lanes and created a change of one additional affected receptor in the traffic noise analysis between the original HOT 3+ Alternative and the refined HOT 3+ Alternative (i.e., Preferred Alternative) (Section 5.2.7). This change did not affect the evaluation of any other environmental impact other than noise.
- Elimination of two flyover ramps on I-290, which would have been located on existing public right-of-way, that were proposed to go over I-88 at the west end of the proposed project. These ramps were found to have little immediate benefit and were omitted; however, they could be installed in the future and within existing public right-of-way.
- The toll rate assumptions were refined for the Preferred Alternative to maintain a 45 mph minimum speed in the HOT 3+ lanes. Toll rates of $0.24/mile during the morning and afternoon peak periods (7:00 a.m. to 9:00 a.m. and 4:00 p.m. to 6:00 p.m.), $0.16 per mile during the peak shoulders and part of the midday (6:00 a.m. to 7:00 a.m., 9:00 a.m. to 10:00 a.m., 2:00 p.m. to 4:00 p.m., and 6:00 p.m. to 8:00 p.m.), $0.12 per mile during the midday period (10:00 a.m. to 2:00 p.m.), and no toll charged overnight (8:00 p.m. to 6:00 a.m.). It should be noted that these toll rates are subject to change, as subsequent Phase 2 detailed financial studies will determine the tolling rates and policies for the HOT 3+ lane.
- The noise impact analysis for the 288 representative noise receptors was updated for the Preferred Alternative. Of the 288 representative receptor locations, 228 (79 percent of these locations) would experience noise impacts and were then evaluated for abatement. As the physical constraints of the urbanized Study Area would prevent construction of earthen noise abatement berms in most locations, the most feasible approach to abating noise impacts in these areas would be to construct a noise barrier wall. The noise barrier study areas for the Preferred Alternative were the same areas that would have been considered for abatement for the four build alternatives, as shown in the Section 3.0 Map Set.
- The recommended locations and heights of noise barriers associated with the Preferred Alternative are provided in Appendix F. Noise barriers are determined "likely to be constructed" where they are supported by the public. Specifically, stakeholders determined to be benefited by these barriers have the opportunity to vote if they want the barrier to be constructed, in a process called "viewpoints

solicitation." Votes are tabulated for each barrier location; barriers receiving at least 50 percent of votes indicating support for construction would be considered "barriers likely to be constructed," and reported as such in this EIS. Barriers that do not receive 50 percent of votes indicating support for construction would not be constructed, in accordance with IDOT policy. Benefitted receptor stakeholders favored the construction of 46 of 63 eligible noise barriers, which would benefit 4,027 receptors. The results of the viewpoints solicitation voting are also included in Appendix F. It is noted that since the B88 Extension wall segments were determined likely to be constructed, it is possible that the construction of the Jane Byrne noise wall in this area may occur concurrently with the construction of the B88 Extension noise wall, to reduce construction costs. It is also noted that the results of the viewpoints solicitation are current for this FEIS and that future local coordination may result in reopening the viewpoints solicitation process where warranted (e.g., by a change in who the affected stakeholders are, a change in the affected stakeholders' opinions, or a change in noise wall technology), as referenced in the "Likelihood Statement" in the project's traffic noise analysis.

It is noted that the above refinements are compatible with the other three build alternatives (except the change in limited-access points, which would not apply to the GP Lane Alternative) and that the differences for comparison of alternatives are small to nonexistent and would not materially affect the identification of the Preferred Alternative.

The cost estimate for the Preferred Alternative was reviewed and adjusted by FHWA during a formal Cost Estimate Review (CER) held in September 2015, and is currently estimated at $2,630 million based on 2015 unit costs escalated to a Year of Expenditure (YOE).

5.5.5 Conclusion

In considering the key factors identified with respect to meeting project goals and objectives, travel performance, and social/economic and environmental impacts, the HOT 3+ Alternative provides the best balance of benefits and avoids social/economic and environmental impacts while providing travel benefits to EJ communities. The quantitative comparison of alternatives in Section 5.4.2 shows that the HOT 3+ Alternative scores higher than the other three build alternatives when measured by either rank (ordinal) or ratio scoring. Because the social and economic and environmental factors are indistinguishable among the build alternatives for most measures, travel performance becomes a principal factor in selecting a Preferred Alternative. The HOT 3+ Alternative demonstrates superior and balanced transportation performance when compared to the other alternatives. It does so by providing a range of travel options providing improved accessibility for all users and by utilizing a managed lane strategy that optimizes throughput while providing a reliable trip time. With the potential financial contribution from projected toll receipts from the HOT lanes, the HOT 3+ Alternative affords flexibility in funding to offset part of the initial construction cost, as well as offsetting part of ongoing operation and maintenance costs. Based on these factors, the HOT 3+ Alternative is selected as the Preferred Alternative.

7.0 List of Agencies, Organizations, and Persons Receiving Final Environmental Impact Statement

The following federal, state, and local agencies, local officials, and public libraries were provided hardcopies of this document for review and comment. Members on the I-290 Eisenhower Expressway e-mail distribution list also received an electronic link to this document.

7.1 Federal Agencies

- Advisory Council on Historic Preservation (ACHP)
- Federal Aviation Administration, Great Lakes Region
- Federal Emergency Management Agency (FEMA), Region 5
- Federal Railroad Administration (FRA)
- Federal Transit Administration (FTA)
- Federal Transit Administration, Region 5
- US Army Corps of Engineers (USACE)
- USACE, Chicago District, Regulatory Branch
- US Coast Guard
- US Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS)
- US Department of Commerce
- US Department of Energy, Office of National Environmental Policy Act (NEPA) Policy and Compliance
- US Environmental Protection Agency (USEPA), Office of Federal Activities
- USEPA Region V, Office of Environmental Review
- US Department of Health and Human Services (HHS)
- HHS, Centers for Disease Control and Prevention
- US Department of Housing and Urban Development, Chicago Regional Office
- US Department of the Interior, National Park Service (NPS)
- US Department of the Interior, Office of Environmental Policy and Compliance
- US Fish and Wildlife Service (USFWS), Chicago Field Office

7.2 State Agencies

- Prairie Research Institute
  - Illinois Natural History Survey (INHS)
  - Illinois State Archaeological Survey (ISAS)
  - Illinois State Geological Survey (ISGS)
  - Illinois State Water Survey (ISWS)
- Illinois Office of Management and Budget
- Illinois Capital Development Board
- Illinois Commerce Commission
- Illinois Department of Agriculture (DOA), Bureau of Land and Water Resources
- Illinois Department of Commerce and Economic Opportunity
- Illinois Department of Natural Resources (Illinois DNR)
  - Division of Natural Heritage
  - Nature Preserves Commission
  - Office of Mines and Minerals
  - Office of Water Resources
  - Office of Realty and Environmental Planning
- Illinois Department of Public Health
- Illinois Environmental Protection Agency (IEPA)
- IEPA, Bureau of Water
- Illinois Emergency Management Agency (IEMA)
- Illinois Historic Preservation Agency (IHPA)
- Illinois State Clearinghouse
- Illinois State Historical Society
- Illinois State Library
- Illinois State Police
- Illinois State Senator Don Harmon
- Illinois State Senator Kimberly Lightford
- Illinois State Toll Highway Authority (ISTHA)

7.3 Local Agencies

Illinois

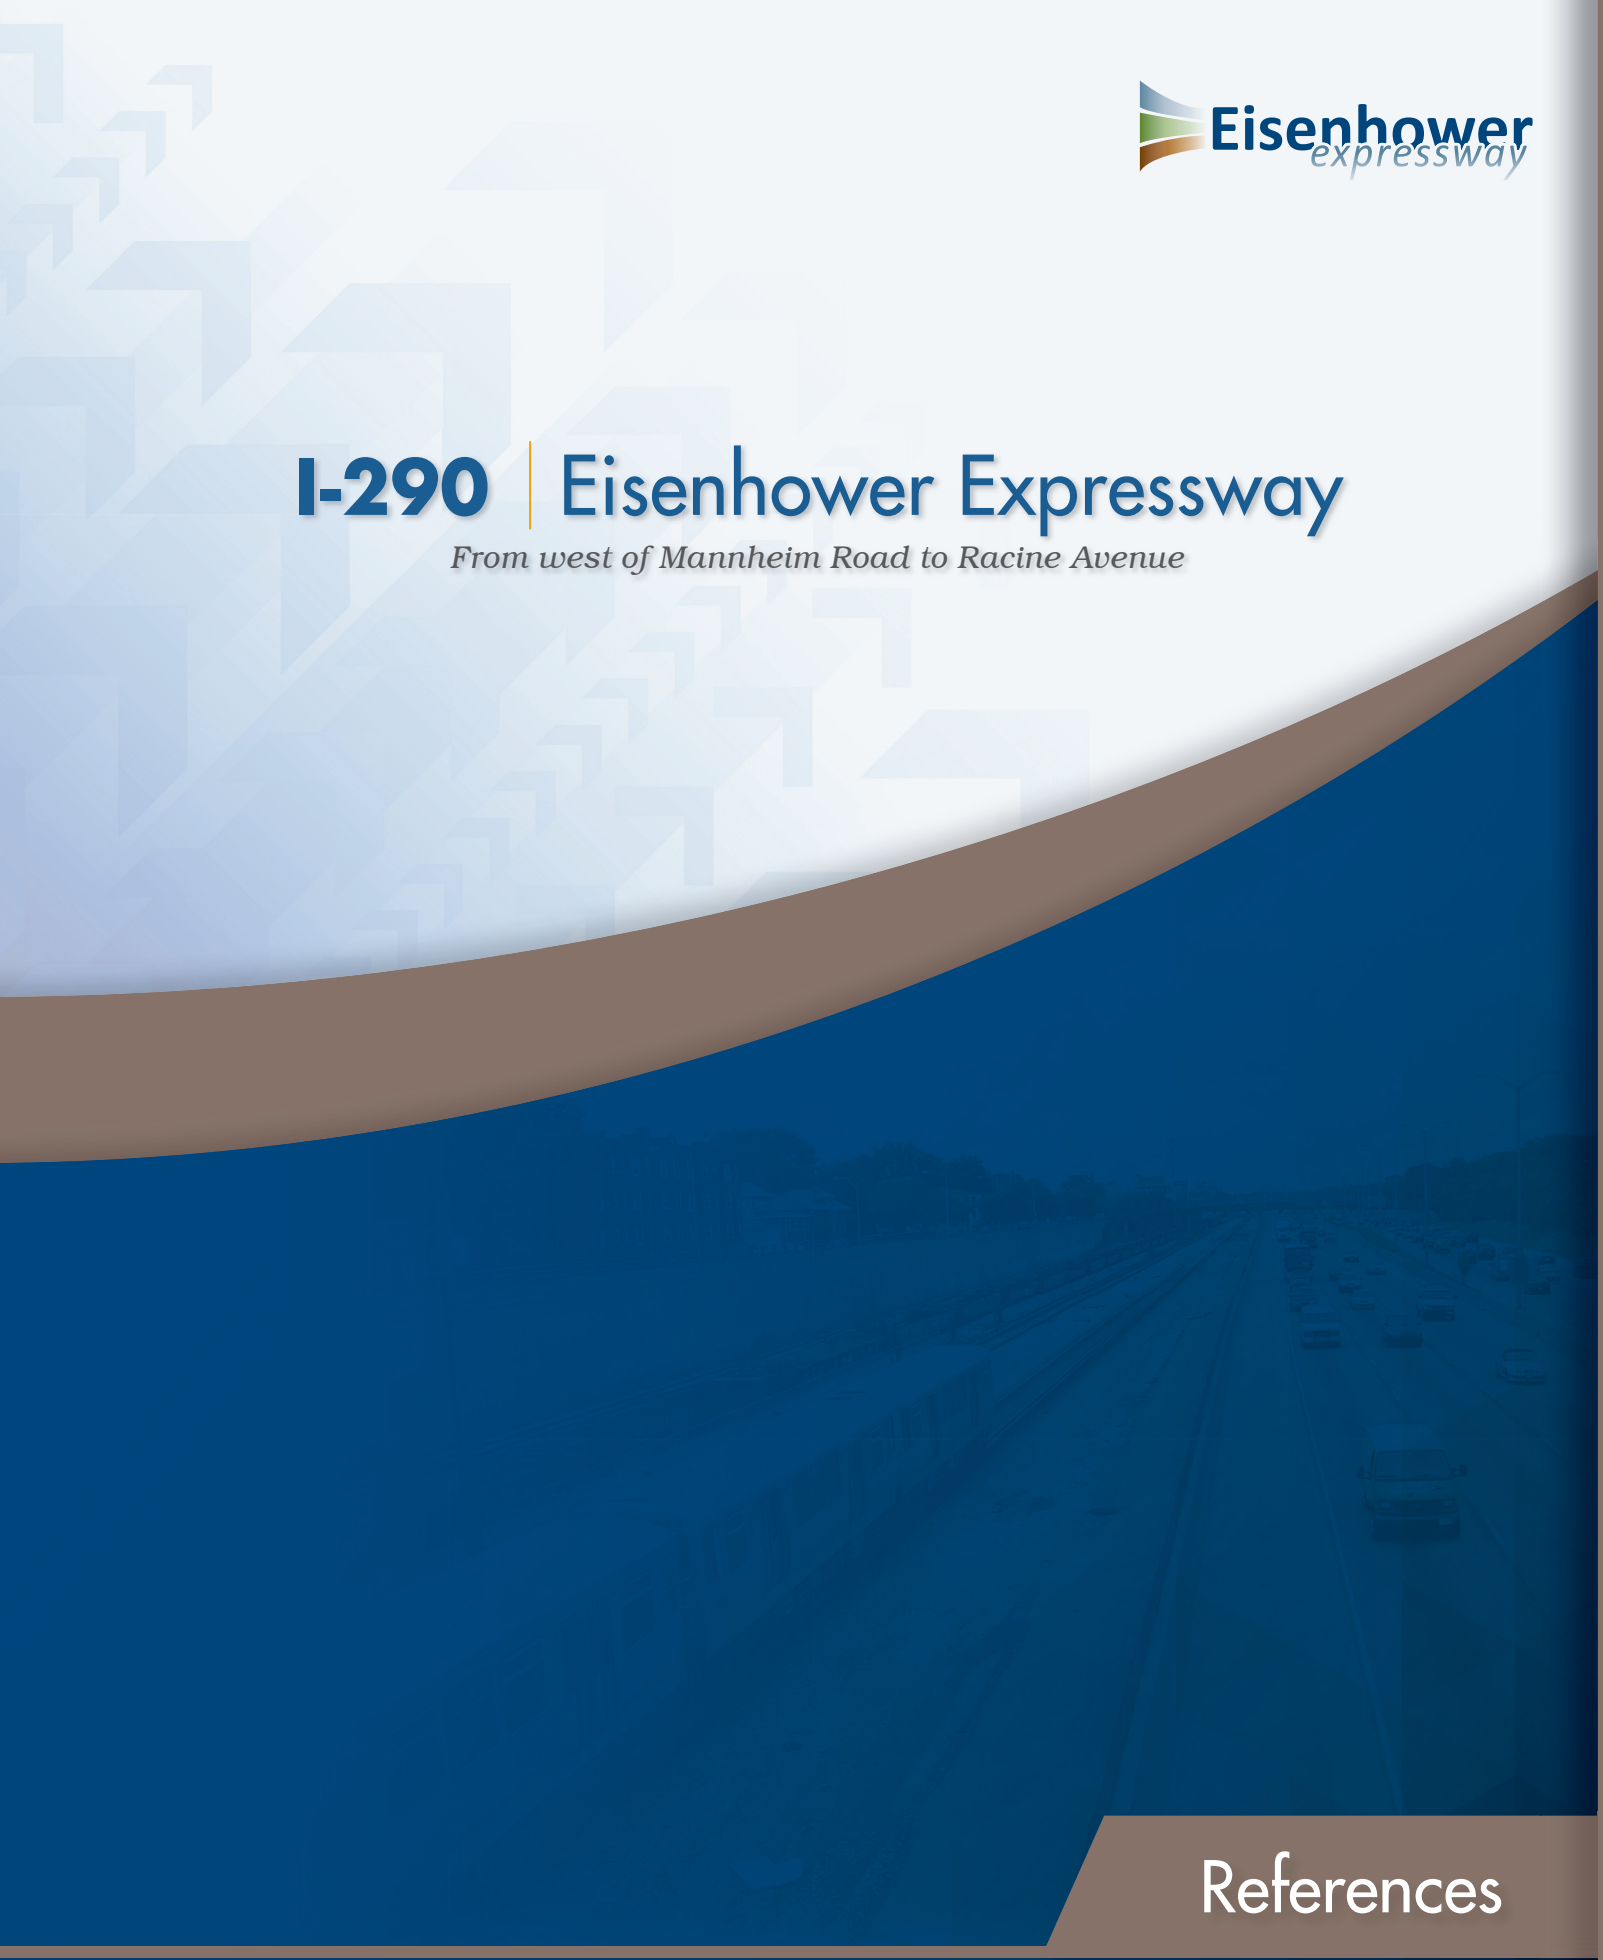
- Communities (county, city, town, township, village)
  - Cook County
  - DuPage County
  - City of Berwyn
  - City of Chicago
    - Ward 24
    - Ward 25
    - Ward 27
    - Ward 28
    - Ward 29
  - Town of Cicero
  - Berwyn Township
  - Cicero Township
  - Leyden Township
  - Oak Park Township
  - Proviso Township
  - River Forest Township
  - Riverside Township
  - Village of Bellwood
  - Village of Berkeley
  - Village of Broadview
  - Village of Brookfield
  - Village of Forest Park
  - Village of Hillside
  - Village of LaGrange
  - Village of Maywood
  - Village of North Riverside
  - Village of Oak Park
  - Village of River Forest
  - Village of Westchester

7.4 Other Stakeholder Groups

- Active Transportation Alliance
- "Cap the Ike" Stakeholder Advisory Committee
- Center for Neighborhood Technology
- Chicago Department of Transportation (CDOT)
- Chicago Department of Water Management
- Chicago Metropolitan Agency for Planning (CMAP)
- Chicago Park District
- Chicago Park District, Board of Commissioners
- Chicago Transit Authority (CTA)
- Citizens for Appropriate Transportation
- City of Chicago Historic Preservation Division/Commission on Chicago Landmarks
- Canadian National Railway Company
- ComEd
- Concordia Cemetery
- Cook County Department of Transportation and Highways
- Cook County Sherriff's Office
- CSX Transportation, Inc.
- DuPage Mayors & Managers Conference
- DuPage County Division of Transportation
- Forest Home Cemetery
- Forest Preserve District of DuPage County (FPDDC)
- Forest Preserve District of Cook County
- Friends of the Oak Park Conservatory
- Friends of the Parks
- Hillside Historical Society and Historical Commission
- Historical Society of Oak Park and River Forest
- Indiana Harbor Belt Railroad
- Illinois Chamber of Commerce, Executive Director – Infrastructure Council
- Illinois Road and Transportation Builders Association (IRTBA)
- Illinois Trucking Association
- Landmarks Illinois

- Metra
- Metropolitan Water Reclamation District
- National Trust for Historic Preservation
- North Cook County Soil and Water Conservation District
- Oak Park Conservatory
- Pace Suburban Bus
- Park District of Forest Park
- Park District of Oak Park
- Preservation Chicago
- Regional Transportation Authority (RTA)
- West Central Municipal Conference
- Village of Maywood Historic Preservation Commission
- Village of Oak Park Historic Preservation Commission

7.5 Public Review Locations



- Bellwood Public Library
- Berkeley Public Library
- Berwyn Public Library
- Broadview Public Library
- Chicago Public Library
- Cicero Public Library
- Forest Park Public Library
- Elmhurst Public Library
- Hillside Public Library
- Maywood Public Library
- Melrose Public Library
- Oak Brook Public Library
- Oak Park Public Library – Main Library
- River Forest Public Library
- Westchester Public Library
- IDOT Region 1 offices, Schaumburg

Crash Analysis Overview 2011-2013 (with 2013-2015 Update)

I-290 Eisenhower Expressway
Cook County, Illinois

Since publication of the Draft Environmental Impact Statement (DEIS), the following substantive changes to this section have been made:

- Addition of Section 8.0 to provide a crash analysis update for the years 2013 through 2015, for the purpose of verifying whether crash trends and causes for the most current 3-year crash period are consistent with the prior year crash statistics that were evaluated for the I-290 Purpose and Need.

Prepared For:

Illinois Department of Transportation

Appendices

Appendix A-1 Crash Data Tables

Appendix A-2 Crash Summary Spot Analysis

This overview is an examination of the three year crash data from 2011 to 2013 and a comparison to the previous three year crash data from 2006 to 2008 that was documented in the Existing Transportation Systems Performance (ETSP) Report Crash Analysis (July 2010) (which covered the portion of I-290 between I-294/I-88 and Cicero Avenue) and the ECTM Crash Addendum 2 (April 2013) (which covered the I-290 extended Study Area between Cicero and Racine avenues that was added to the I-290 Study following the initial crash analysis).

In addition, recent crash data from 2014 and 2015 is included in a separate 2013-2015 updated study period to determine if previous crash trends remain valid (Section 8.0 of this Appendix).

1.0 Influences on Crash Data

In 2009, the state of Illinois raised the threshold for reporting property damage only (PDO) crashes from $500 to $1,500. This new threshold has the effect of lowering the total number of crashes reported since the PDO crashes with damage less than $1,500 will no longer be reported. There were no changes in reporting for fatal and injury crashes.

In 2010, the Eisenhower Expressway was being resurfaced and was under construction zone traffic operations for the majority of the year. As this does not represent the normal operating conditions of the expressway, 2010 crash data was not utilized.

Therefore, the next continuous three years of consistent crash data that was available at the time of this analysis was the period from 2011 through 2013.

2.0 I-290 Mainline Overview

For the 2011-2013 reporting period, the total number of mainline crashes for the project was 5,365; this compares to 6,173 crashes for 2006-2008 reporting period; representing a 13 percent overall reduction in total reported crashes. The reduction in the three-year reported PDO crash rate can be partially attributed to the change in the reporting cost threshold. However, it is also noted that K and A type crashes, as well as all injury crashes (Types K, A, B and C), also declined during the same period even though the reporting methods did not change[1]. These K, A, B and C crashes went down from 95 in 2006-2008 to 79 in 2011-2013, a 19 percent reduction. There was an increase in overall and PDO crashes each year in the 2011-2013 period; however, there was no consistent pattern to the K and A crashes, as they varied each year in the 2011-2013 period, just as they did in 2006-2008 except in the following locations:

[1] Type K crashes include a fatality. Type A crashes include an incapacitating injury. Type B crashes include a visible, non-incapacitating injury. Type C crashes include no visible injury, but a complaint of pain.

- Eastbound (EB): Clusters of Type A crashes occurred near Kostner, Western and Ashland avenues

- Westbound (WB): A cluster of Type A crashes occurred near Central Avenue in the westbound direction.

There was one more Type K crash in 2011-2013 than there was in 2006-2008, and there were 17 less Type A crashes in 2011-2013 than there were in 2006-2008.

The general decrease in overall, PDO, injury, and K and A crashes from 2006-2008 to 2011-2013 may be partially explained in the context of the overall statewide crash experience in Illinois. For instance, in 2006, there were 408,670 crashes, 106,918 injuries, and 1,254 deaths reported for Illinois highways. By 2011, those numbers had been reduced statewide to 281,788 crashes, 84,172 injuries, and 918 fatalities[2]. As indicated previously, the decrease in total crash number is partially explained by the increase in PDO threshold, but the injury and fatality data also show declines of 21percent and 27 percent, respectively, over the five-year period.

It is noted that IDOT's Strategic Highway Safety Plan was implemented in cooperation with the Federal Highway Administration as a result of the 2005 federal SAFETEA-LU legislation, with emphasis on the "4 E's" - engineering, education, enforcement, and emergency medical services, with ten targeted emphasis areas. Continuing efforts to reduce the number and severity of crashes and injuries as part of that plan are reflected in the lower overall crash experience over its course, as indicated in IDOT's 2011 SHSP Progress Report[3]. In addition, crash frequencies may have been influenced by decreased travel during the Great Recession of late 2007 to early 2009 and the following economic recovery. The FHWA reports that as of July 2015, national vehicle miles of travel (VMT), which peaked in 2007 and then regressed to a lower level in 2009-2010, have climbed back to a level similar to 2007[4].

3.0 Trends within Sections of the I-290 Mainline

The July 2010 ETSP Report included a breakdown of crash data for nine EB and WB logical sections within the I-290 mainline from west of Wolf Road to Kostner Avenue. These sections were established to determine the relationship between crash rate, severity, type, time of day and the characteristics of the roadway, and were chosen on

[2] Illinois Crash Data 2006-2010 and 2007-2011, retrieved at http://www.idot.illinois.gov/transportation-system/safety/Illinois-Roadway-Crash-Data on February 25, 2015.

[3] Strategic Highway Safety Plan Progress Report, IDOT, July 2011 http://www.idot.illinois.gov/transportation-system/transportation-management/planning/SHSP

[4] FHWA, July 2015 Traffic Volume Trends, retrieved at http://www.fhwa.dot.gov/policyinformation/travel_monitoring/15jultvt/page2.cfm on October 21, 2015.

the basis of direction of travel, consistent number of lanes, similar shoulder widths and by locations between major crossroads. With the Study Area extending east to Racine Avenue, breakdowns were expanded to 20 logical sections (the original nine, plus 11 more extending from Kostner Avenue to Racine Avenue). The 2006-2008 and 2011-2013 reporting periods, as well as a combined 2006-2008 and 2011-2013 six-year reporting period, are both included for comparison purposes in Appendix A-1. Each EB and westbound section is ranked for "all crashes", "injury crashes", and "number of injuries" with further information and breakdowns on crash rate and overall ranking (EB and WB included).

In comparing the 2011-2013 data to the 2006-2008 data, the relative highest crash sections are in similar locations.

- Ashland Avenue to Racine Avenue (EB) – This section had the highest EB and second highest overall crash rate in 2006-2008, the highest overall crash rate in 2011-2013, and the highest injury crash rate for both periods (EB and overall). There are queues that form in the EB direction due to a lack of interchange capacity, with rear-end crashes being the predominant type. It is noted that the ongoing improvements to the Jane Byrne (formerly Circle) Interchange are expected to improve capacity and safety along this section.

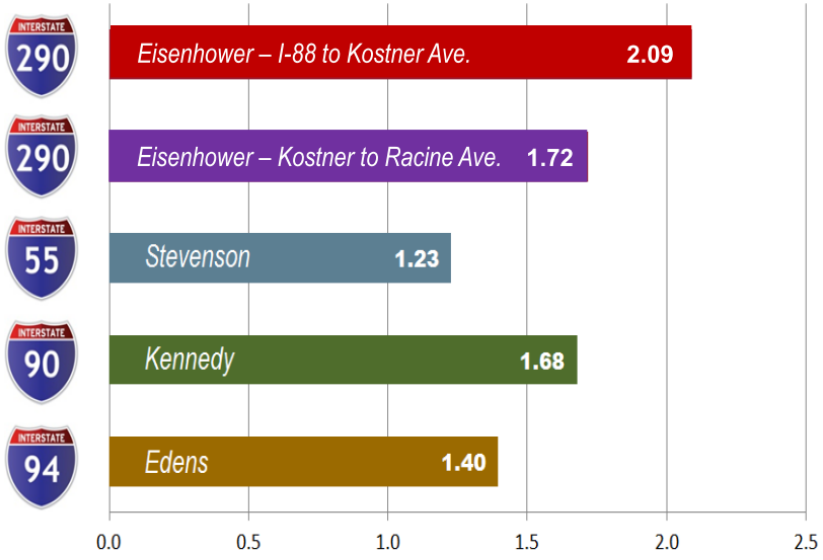
Other locations that have relatively high crash rates and injury crashes include:

- Westchester Boulevard to 25th Avenue (EB) – This section had the second highest EB crash rate in both study periods. The crash experience is related to the loss of mainline traffic capacity at the EB lane drop at 25th Avenue and the resulting queues and difficulty in making weaving movements.

- Austin Boulevard to Laramie Avenue (WB) – This section had the highest overall WB crash rate in both study periods. The crash experience is related to the left-hand ramps and the WB lane drop at Austin Boulevard. The presence of left-hand ramps results in entering and exiting traffic needing to make weaving movements for access and slower-speed ramp users mixing with higher-speed through users. The loss of mainline traffic capacity at the WB lane drop results in queues and difficulty in making weaving movements.

- CSX Railroad to East Avenue (WB) - This section had the third highest WB crash rate in both study periods, and is within the influence area of the left-hand ramps at Harlem Avenue.

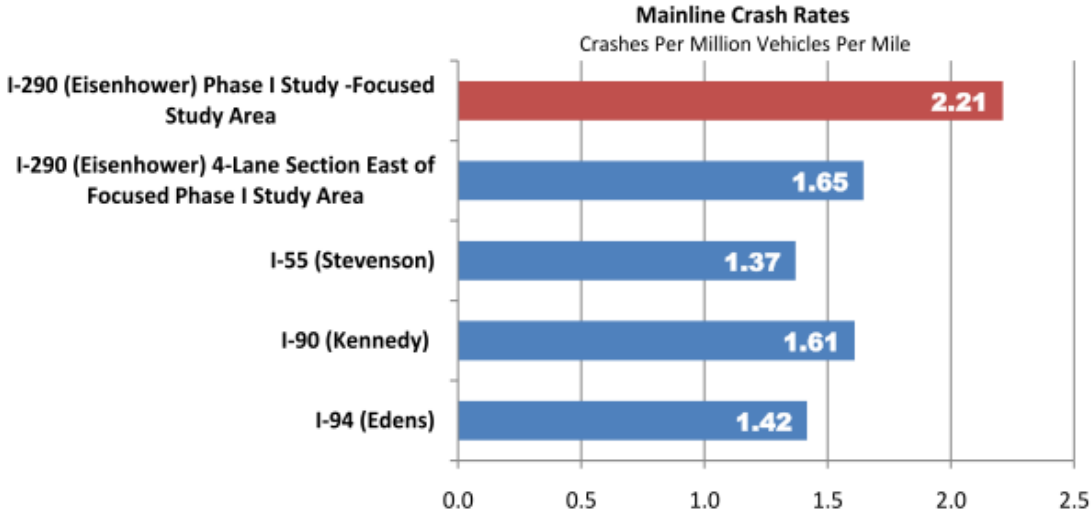
3.1 Type K and A Crashes



Generally, Type K and A crashes do not seem to follow a similar pattern within the 2006-2008 and the 2011-2013 study periods. Specific areas with somewhat similar groupings of Type A crashes include sections near Kostner, Western and Ashland avenues in the EB direction and Central Avenue in the WB direction. There was one

more Type K crash in 2011-2013 than there was in 2006-2008, and there were 17 less Type A crashes in 2011-2013 than there were in 2006-2008.

3.2 Crash Rate Trends with Comparative Expressways

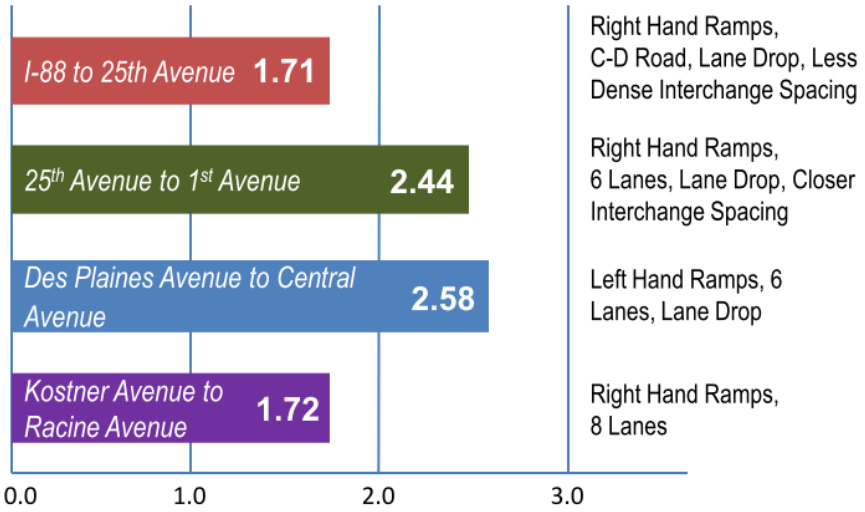


I-290 crash data and traffic volumes were compared to other Chicago area expressway sections on I-90, I-94 and I-55. The results are shown in Figure 3-1. Crashes per million vehicles per mile were calculated for each section of the local expressways using the crash data and traffic volumes from both of the three-year study periods (2006-2008 and 2011-2013). The Eisenhower Expressway reconstruction area, I-294/I-88 to Kostner Avenue, had the highest crash rate of all the Chicago area expressways sections that were studied. Further, the Eisenhower section from Kostner Avenue to the Jane Byrne Interchange had the second highest crash rate. The crash rates for the extended study period are similar to those presented in the ESTP Report Crash Analysis (July 2010) in Figure 3-2, which also showed the Eisenhower Expressway reconstruction area (shown as Focused Study Area) having the highest crash rate among the same comparative expressway sections.

Figure 3-1. Comparative Crash Rates – Chicago Area Expressways (2006-2008, 2011-2013)

Note: Values Calculated as Crashes per Million Vehicle Miles
Source: WSP Parsons Brinckerhoff, 2015

Figure 3-2. Comparative Crash Rates – Chicago Area Expressways (2006-2008) from June 2010 ESTP Crash Analysis



Source: WSP Parsons Brinckerhoff, 2010

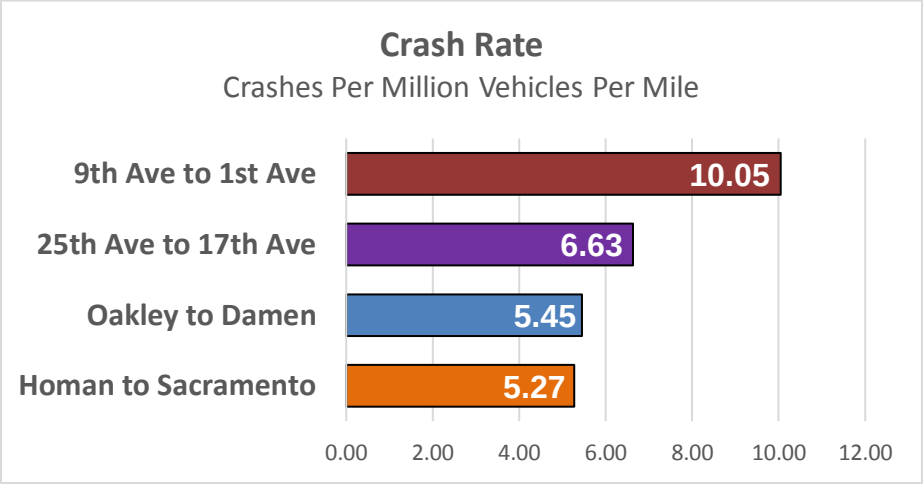
3.3 Crash Rate Trends within Comparative Sections of I-290

To follow up on the section analysis above, sections with similar geometric characteristics were grouped. This analysis found that there are variations in the crash experience based on the underlying characteristics of the roadway, as shown in Figure 3-3.

Figure 3-3. Crash Comparison of I-290 Mainline Sections (2006-2008, 2011-2013)

Note: Values Calculated as Crashes per Million Vehicle Miles
Source: WSP Parsons Brinckerhoff, 2015

For example, the section between Kostner Avenue and Racine Avenue has eight travel lanes, conventional right-hand ramps and less dense interchange and ramp spacing than the section between 25th Avenue and 1st Avenue, and had a crash rate of 1.72 crashes per million vehicle miles in the combined 2006-2008 and 2011-2013 reporting periods. A higher crash section is located from 25th Avenue to 1st Avenue; this section has four interchanges each direction located within a 1.5 mile distance, six travel lanes, and a lane drop from four to three lanes EB at 25th Avenue; this section has a crash rate of 2.44, which is higher than the average overall crash rate of I-290 from I-294 to Kostner Avenue. The section between DesPlaines Avenue and Central Avenue (which includes the Harlem Avenue and Austin Boulevard interchanges) has an even higher combined crash rate of 2.58; this section contains two interchanges with left-hand ramps, a lane drop from four to three lanes WB at Austin Boulevard, and six travel lanes from DesPlaines Avenue to Austin Boulevard. The section between I-88 and 25th Avenue contains a lane drop from four to three lanes at 25th Avenue in the EB direction; its crash rate is a relatively low 1.71 compared to other sections of I-290, but is relatively higher compared to other expressways in the region.



In the sections with higher crash rates, the presence of lane drops, dense interchange spacing, left-hand ramps, and/or less mainline lane capacity contributes to the higher crash experience of those sections.

The six-lane section of I-290 between 25th Avenue and 1st Avenue was also further broken down for purposes on analyzing sections where changes in access were considered (between 25th Avenue and 17th Avenue, and between 9th Avenue and 1st Avenue). These sub-sections have slip ramps connecting parallel frontage roads to I-290. Two sub-sections along the eastern eight-lane section of I-290 that were closest in ramp length and geometry to 9th Avenue and 1st Avenue were selected, at Homan Avenue to Sacramento Avenue and at Oakley Avenue to Damen Avenue. It is noted that the eastern sub-sections benefit from the presence of an additional mainline lane in each direction and an auxiliary lane to aid in weaving maneuvers from ramp to mainline and vice versa, both of which would contribute to a predicted reduction in crashes.

Compared to the remaining two, eight-lane expressway sub-sections, the successive ramps between 9th Avenue and 1st Avenue have a crash rate that is nearly double that of the similar ramp sections to the east. There were no eight-lane sections identified in the east that were found to be similar enough in design to compare to the 25th Avenue and 17th Avenue ramp pair. However, the crash rate between 17th Avenue and 25th Avenue, although elevated, is not as severe as the existing crash rate between 9th Avenue and 1st Avenue. Figure 3-4 shows a comparison of crash rates at these sub-section locations.[5]

[5] Comparative Safety Analysis, 25th Avenue to 1st Avenue Ramp Configuration, WSP Parsons Brinckerhoff, 2016

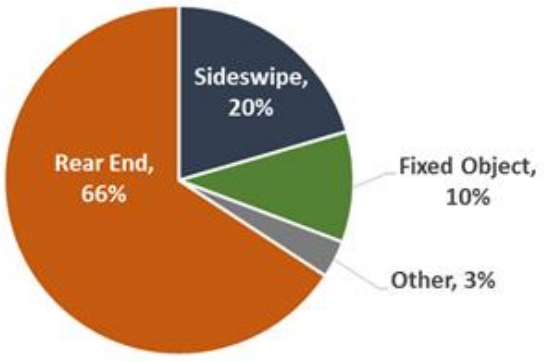
Figure 3-4. Crash Comparison of I-290 Mainline Sub-Sections (2011-2013)

Source: WSP Parsons Brinckerhoff, 2016

3.4 Prevalent Crash Types

For this analysis, the 2006-2008 as well as the 2011-2013 data were combined to determine the comprehensive crash type trends. The overall predominant crash type along I-290 is rear-end (66 percent overall on a 24-hour basis) with 88 percent of rear-end crashes occurring during the peak period and midday congested travel periods between 6 AM to 11 PM (Figure 3-5 and Figure 3-6). During congested periods, rear-end collisions represent 75 percent of all crashes. National studies, as well as field observation of I-290 within the Study Area, indicate congestion as a primary cause of rear-end crashes due to erratic, stop and go traffic conditions with reduced space (headway) between vehicles that requires increased driver attentiveness to react to those conditions.

Figure 3-5. Overall Crash Type (2006-2008, 2011-2013)



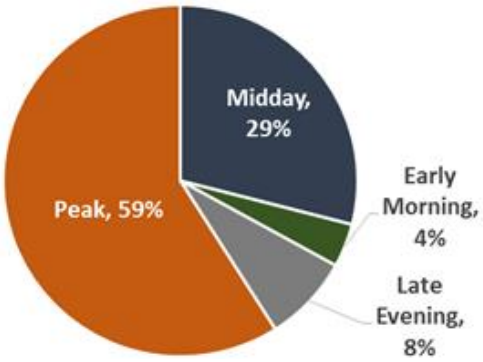


Figure 3-6. Rear-end Crash – Time of Day (2006-2008, 2011-2013)

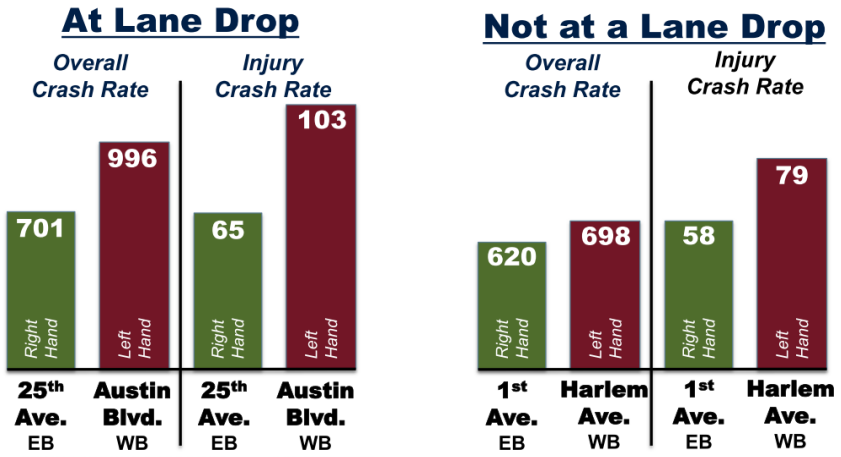

Source: WSP Parsons Brinckerhoff, 2015

The other two prevalent crash types on the I-290 mainline are same-direction sideswipe and fixed object collisions off the roadway, which represent approximately 20 percent and 10 percent of overall crashes, respectively. Many same-direction sideswipes correlate to areas where there are numerous lane-changing and weaving movements, such as near entrance and exit ramps. Most of the same-direction sideswipes are also occurring during congested conditions.

4.0 Lane Drop and Left-Hand Ramp Analysis

An analysis was also done of the relationship between left-hand ramps, lane drops and crashes in both directions along the I-290 Mainline for both study periods (Figure 4-1). Four locations were studied: 25th Avenue and 1st Avenue EB and Austin Boulevard and Harlem Avenue WB.

Figure 4-1. Left Lane Drop/No Lane Drop and Left-Hand/Right-Hand Crash Rates (2006-2008, 2011-2013)

Note: Values Calculated as Crashes/Injury Crashes per Mile
Source: WSP Parsons Brinckerhoff, 2015

The analysis shows that, for locations where there is a left-hand ramp, the crash rate and injury rates (normalized to a per-mile rate) are higher than a comparable right hand ramp location, either at a lane drop or not.

- At Austin Boulevard WB, where there is a lane drop as well as left-hand ramps, the crash rate and injury rate were 996 and 103, respectively.

- At 25th Avenue EB, where there is a lane drop but not left-hand ramps, the crash rate and injury rate were somewhat lower than Austin Boulevard's results at 701 and 65, respectively.

- At Harlem Avenue WB, where there are left-hand ramps, the crash rate and injury rate were 698 and 79, respectively.

- At 1st Avenue EB, an interchange between 25th and Harlem avenues with neither a lane drop nor a left-hand ramp, the crash rate and injury rates were the lowest of the four locations studied. The crash rate and injury rate at this location were 620 and 58, respectively.

5.0 Hot Spot Analysis

Three I-290 mainline crash "hot spots" were identified from the 2006-2008 data and a detailed analysis of crashes was performed at these locations. Individual crash reports were reviewed for all crashes to identify any other potential trends due to distracted driving, glare, lane position, and more. The same analysis was completed for 2011-2013 (Appendix A-2).

In the EB direction, the hot spot from Mannheim Road to 17th Avenue exhibits these comparisons between 2006-2008 and 2011-2013:

- Generally the same trends in 2011-13 as in 2006-2008

- A majority of crashes happen during peak hours (66 percent)

- The top three causes of accidents remain the same:

  – Failure to reduce speed to avoid crash,

  – Following too closely, and

  – Improper lane usage.

- Age distribution is almost identical

- Crashes in the left and right lanes are higher than in the center lane

In the WB direction, the hot spot at Harlem Avenue and Austin Boulevard exhibit these comparisons between 2006-2008 and 2011-2013:

- Generally the same trends in 2011-2013 as in 2006-2008

- A majority of crashes happen during peak hours (74 percent at both locations)

- The top three causes of accidents remain the same:

  – Failure to reduce speed to avoid crash,

  – Following too closely, and

  - Improper lane usage.

- Age distribution is almost identical

- Nearly half of the crashes at Harlem Avenue and at Austin Boulevard were in the left (innermost) lane, where a lane position was reported.

The two highest concentrations of crashes in the WB direction are along the sections of I-290 approaching the Austin Boulevard and Harlem Avenue interchanges, and the highest crash rate within the project limits is the WB approach to Austin Boulevard (539 crashes per mile for 2006-2008, 459 crashes per mile for 2011-2013). This is substantially higher than the next highest location at the EB approach to the Ashland Avenue interchange (390 crashes per mile for 2006-2008, 368 crashes per mile for 2011-2013).

In addition, of the crashes that had an identified lane position in the police reports, 74 percent (2006-2008) and 77 percent (2011-2013) were in the inner two lanes at Austin Boulevard, and 47 percent (2006-2008) and 45 percent (2011-2013) were in the inside lane at Harlem Avenue. This crash experience can be attributed to the inside lanes on an expressway typically serving higher speed, longer distance travel; the inside ramps introduce merging and speed changes.

6.0 Cross Road Analysis

Cross roads are those roads that traverse I-290 in the Study Area via a grade separation. As part of this study, the cross roads between I-88 and Racine Avenue were examined. The cross roads east of Cicero Avenue are being evaluated as part of a separate improvement study and are not documented in this report. The following general observations are made (Table 6-1):

- The number of injuries on the cross roads is very similar for both time periods (187 in 2006-2008 as compared to 172 in 2011-2013).

- 251 less cross road crashes occurred in 2011-2013 than in 2006-2008. This is likely due in part to the PDO cost adjustment.

- The highest ranked crash locations in number of crashes (#1 through #10) were at crossroads where there was also interchange access to I-290. This trend is also apparent when crash rate is considered, with only Oak Park Avenue, a no access location, having a higher crash rate than two crossroad locations with interchange access (25th Avenue and DesPlaines Avenue). These elevated number and rate of crashes can be attributed to increased traffic, congestion and conflicting traffic movements at interchange access locations as compared to no access locations.

Table 6-1. 2006-2008, 2011-2013 Cross Road Crash Summary I-290 from I-294/I-88 to Cicero Avenue

Cross Street	Eval. Length (miles)	I-290 Access	Crashes			Injuries		Predominant Crash Factors							
			Total	Crash Rate	RANK		Injury Rate	Crash Type		Weather		Road Condition		Time Period	
25TH Ave	0.30	Full - Direct/Slip Ramps	169	563	3	51	170	Rear end	49%	Clear	80%	Dry	74%	Midday	39%

Crossroad Total		**1.76 Miles**	**1575**			**359**		**Rear end**	**33%**	**Clear**	**76%**	**Dry**	**71%**	**Midday**	**32%**

Notes:

1. Study Area cross roads east of Cicero to Racine Avenue not evaluated.
2. 1st Avenue and Cicero Avenue are tied at #4 in crash rank, having 166 crashes at each crossroad; crash rank continues at #6 (Central Avenue).

Source: WSP Parsons Brinckerhoff, 2015

The greatest number of crashes for the combined 2006-2008 and 2011-2013 study period were at Harlem Avenue (highest) and Austin Boulevard (second highest), and these cross roads also had the highest crash rates. There was a substantial drop in number of crashes at 25th Avenue. At the Harlem Avenue and Austin Boulevard locations, queues due to insufficient intersection capacity and inefficient signal phasing and green time allocation due to the geometric constraints of the intersection and ramps were contributing factors.

7.0 Frontage Road Analysis

Frontage roads are those roads that serve local traffic and run parallel to and adjacent to I-290. Frontage roads within the Study Area between I-88 and Cicero Avenue were examined to determine any comparative differences in the crash experience among the 2006-2008 and 2011-2013 study periods. Since no geometric or traffic management changes to the frontage roads east of Cicero Avenue are included as part of this study, the crash experience of those frontage roads is not examined here. The following observations are made (Table 7-1).

- Crashes with parked motor vehicles were the most predominant crash type.
- Other predominant crash types include rear-end and sideswipe crashes.

Indian Joe Drive, Beach Street and Lexington Street, which form a continuous route and also serve to carry traffic from the EB off-ramp for 25th Avenue, are ranked first, third and second highest in crash rate respectively for the combined 2006-2008 and 2011-2013 study period. Contributing factors to crashes along these sections include mixing ramp through traffic with local traffic (which is further complicated by the stop-control intersection where the EB off-ramp intersects with Indian Joe Drive and Gardner Road, stop sign placement is not ideal because of the geometry, and EB vehicles from the ramp conflict with two-way traffic), and the 90° bends where Indian Joe Drive meets Beach Street and where Beach Street meets Lexington Street, which have posted 20 mph advisory speed limits in an otherwise 30 mph posted speed zone.

Table 7-1. 2006-2008, 2011-2013 Frontage Road Crash Summary I-290 from I-294/88 to Cicero Avenue

Frontage Road	From Street To Street	Segment	One/Two Way	Length	Crashes			Injuries		Predominant Crash Factors

Note: Study Area frontage roads east of Cicero to Racine Avenue not evaluated.
Source: WSP Parsons Brinckerhoff, 2015

8.0 2013-2015 Update

A review of the most current crash data available from years 2014 and 2015 was completed to compare with the earlier crash analysis performed for the I-290 Phase I Study area from West of Mannheim Road to Racine Avenue. In order to examine the recent crash data on a comparable basis, the previously available 2013 crash data was utilized and combined with the 2014 and 2015 crash data in order to provide a 3-year comparison period, as with the previous 2006-2008 and 2011-2013 crash analyses.

8.1 Overall Crash Statistics

With respect to safety and the I-290 Purpose and Need, the overall crash statistics for the 2011-2013 period were compared to the 2013-2015 crash period that includes the most current available 3-years of data. The following table provides a comparison of the crash statistics for the entire corridor between I-294/I-88 and Racine Avenue.

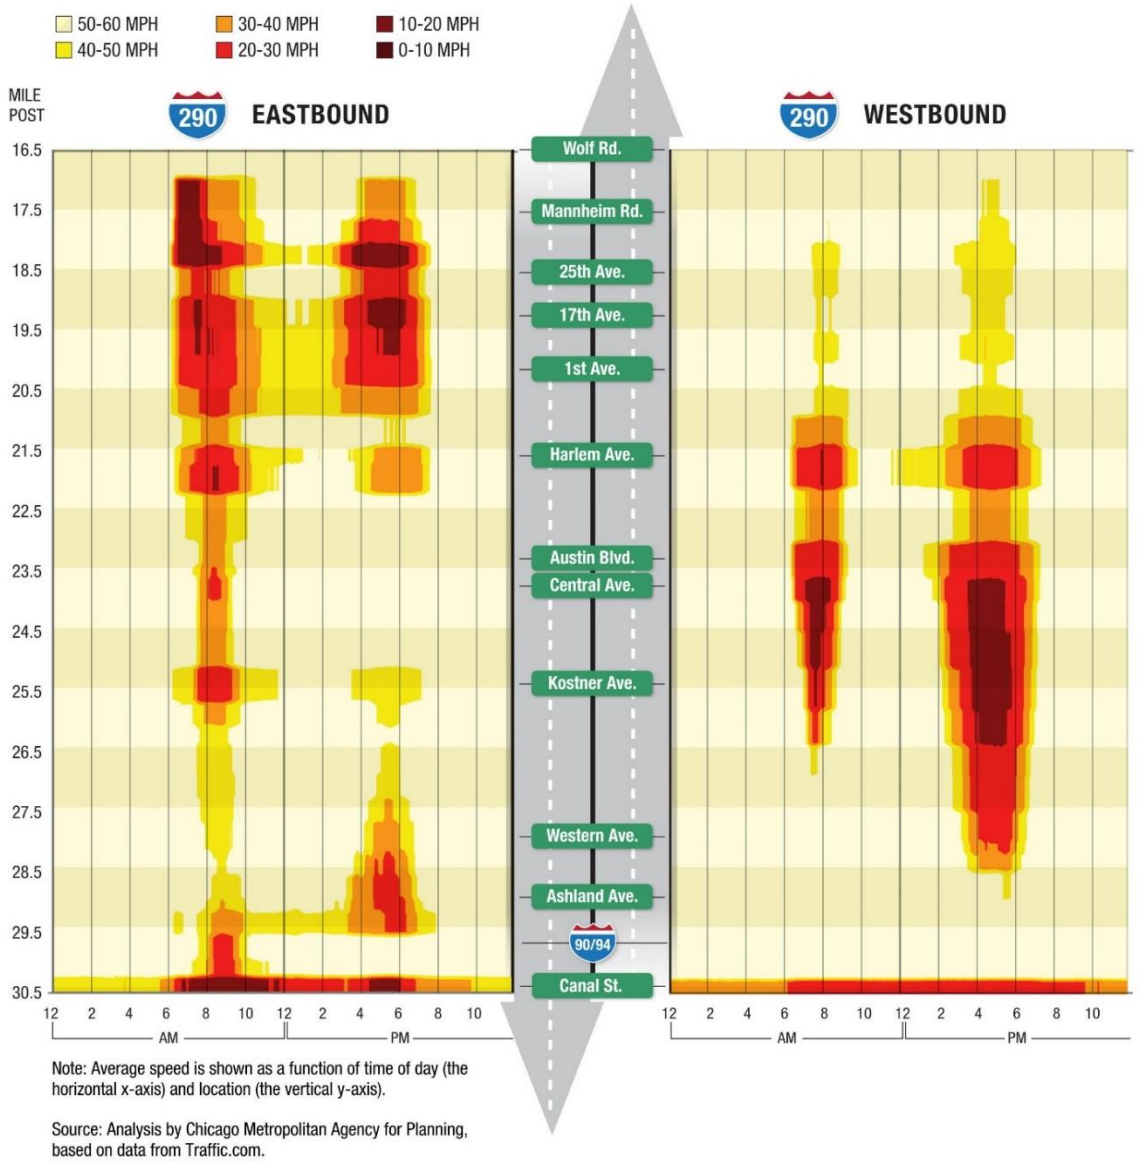

Table 8-1. Comparison of 2011-2013 and 2013-2015 Mainline Crashes I-290 from I-294/88 to Racine Avenue

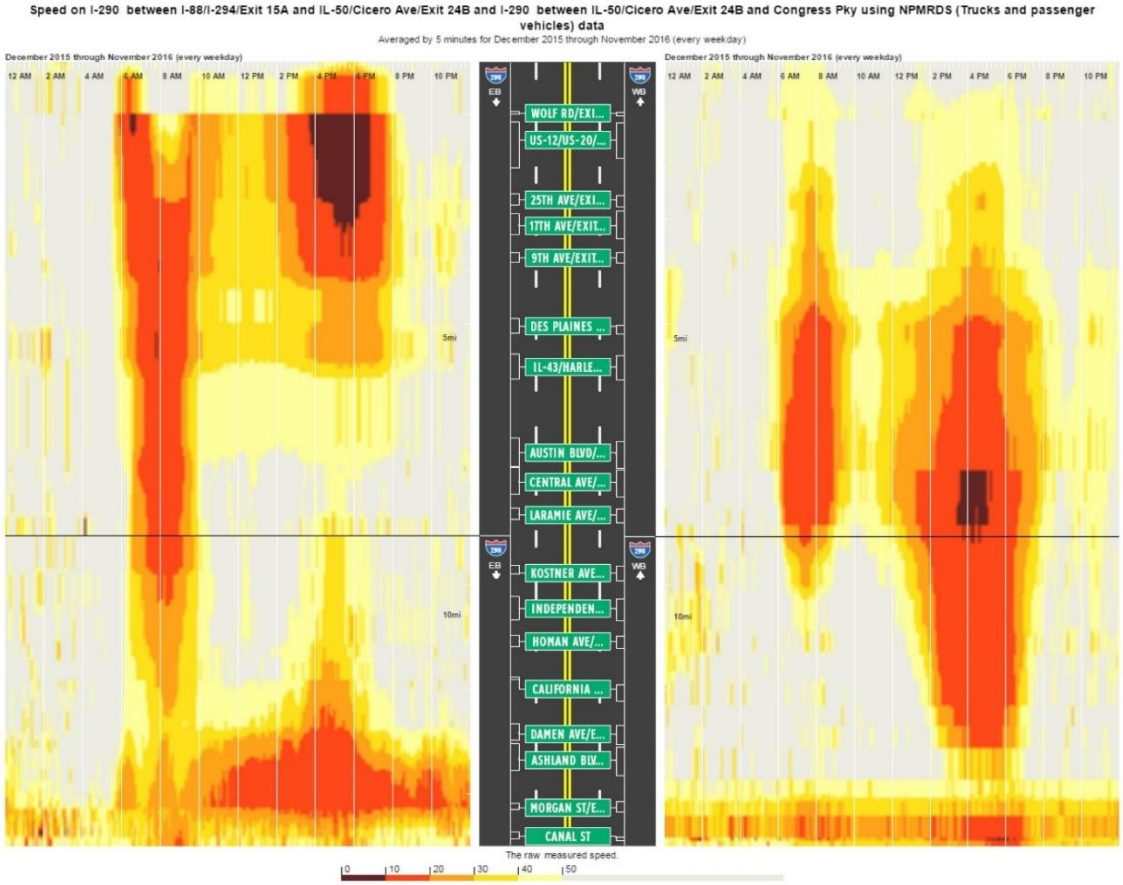
YEAR	Total K + A Crashes	Total Injury Crashes	Total PD Crashes	Total Overall Crashes
2011	20	241	1,426	1,667
2012	36	234	1,567	1,801
2013	23	236	1,661	1,897
Total	79	711	4,654	5,365
Annual Ave	**26**	**237**	**1,551**	**1,788**
2013	23	236	1,661	1,897
2014	16	112	1,824	1,936
2015	27	135	2,027	2,162
Total	66	483	5,512	5,995
Annual Ave	**22**	**161**	**1,837**	**1,998**
	-15%	-32%	+18%	12%

The comparison indicates that overall crashes have increased by 12 percent in 2013-2015 while injury crashes have decreased by 32 percent. Generally, this indicates that there are a greater number of lower speed crashes that would be associated with congestion, indicating that increased congestion is the primary contributing factor.



In visually comparing CMAP's Congestion Scan Maps of the I-290 corridor between year 2011 and year 2016, the congestion is more pronounced in the 2016 congestion scan. This supports a conclusion that congestion plays a key role in the increased crash rate.

Figure 8-1. CMAP - I-290 Congestion Scan 2011 Average Weekday Speeds on I-290

(Tuesday thru Thursday)

Figure 8-2. CMAP - I-290 Congestion Scan 2016 Average Weekday Speeds on I-290 between December 2015 and November 2016

In comparing crash rate changes within major eastbound and westbound sections, it was found that crash rates were particularly elevated for the eastbound lanes between Kostner Avenue and Racine Avenue, as compared to the other broad directional sections of the expressway.

Table 8-2. Comparison of I-290 Crash Rate Change by Section: 2011 through 2013 and 2013 through 2015

	EB			WB		
Location	**'11 to '13**	**'13 to '15**	**Δ %**	**'11 to '13**	**'13 to '15**	**Δ %**
I-88 to Kostner	1797	2002	**11%**	1939	2061	**6%**
Kostner to Racine	916	1155	**26%**	713	777	**9%**

This section experienced a 26 percent increase in crash rates for the most recent 3-year period as compared to the 2011 through 2013 three year period. This increased crash rate coincides with the Jane Byrne Interchange construction and maintenance of traffic activities that were occurring during 2014 and 2015. Increased congestion through the work zone, and congestion spill back upstream of the work zone are likely the primary contributors to the higher change in crash rates in this section of I-290, as indicated by the CMAP congestion scans.

8.2 Crash Types

A comparison of crash types was performed to determine if there were any appreciable changes in the mix and timing of crashes. Figure 8-3 compares the previous crash type/time statistics that were summarized against the latest 3 year period statistics.

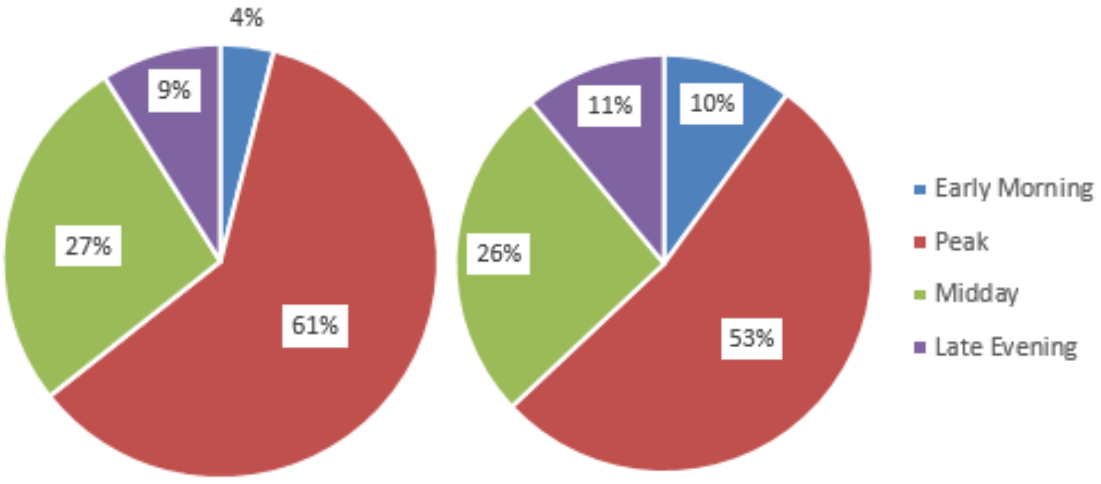


Figure 8-3. Comparison of Overall Corridor Crash Types: 2011 through 2013 and 2013 through 2015

2011 through 2013 **2013 through 2015**

The analysis shows that the mix of crash types is consistent between the two periods, indicating that the general crash causes/factors have not changed between the two analysis periods. Rear-end crashes remain the predominant crash type, followed by side-swipe crashes, for which congestion is typically attributed as the primary reason for these types of crashes. To substantiate that congestion was still a key factor in rear-end crashes for the latest 3-year period, a time of day comparison was made. Figure 8-4 demonstrates that the majority of rear-end crashes continue to occur during the peak and mid-day time periods.

Figure 8-4. Comparison of Rear-End Crashes – Time of Day: 2011 through 2013 and 2013 through 2015

2011 through 2013 **2013 through 2015**

8.3 Conclusion

Based on a review of the most current crash data, it is concluded that the crash trends and causes for the most current 3-year crash period are consistent with the prior year crash statistics that were evaluated for the I-290 Purpose and Need. Increases in crash rates during the most recent 3-year crash analysis period are attributed to an increase in overall I-290 congestion levels and duration, as indicated by the CMAP 2011 and 2015-2016 congestion scans.

1.0 Introduction

1.1 Purpose of the Technical Memorandum

The purpose of this memorandum is to summarize the I-290 travel modeling process and methodology, to present the assumptions used in the effort, and to provide the results of the validation of the base year scenario. This document will be organized as follows:

1. Introduction
    a. Background of the I-290 Model Update Process
    b. Opportunity & Need for I-290 Model Enhancement
2. Model Preparation
    a. Zone System
    b. Network
    c. Socioeconomic Data
3. Model Enhancements
    a. Trip Generation
    b. Trip Distribution
    c. Mode Choice
    d. Traffic Assignment
4. 2010 I-290 Model Validation Results
    a. Regional Level Traffic Validation (Six County)
    b. Peak Period Traffic Validation
    c. Peak Period Volume/Capacity Ratios
    d. I-290 Corridor Daily Traffic Validation

1.2 Background of the I-290 Travel Model Process

The I-290 travel model development and application is part of a larger preliminary engineering and environmental impact statement that includes alternatives evaluation, noise analysis, air quality analysis, geometric design studies, traffic and safety studies, and economic and financial analyses that require inputs from the travel model.

An initial feasibility study of a high occupancy vehicle (HOV) lane on I-290 Eisenhower Expressway was completed in 1998[i]. The feasibility study contained 1990 and 2010 future traffic estimates for an HOV lane and the general purpose lanes. Since the HOV lane feasibility study, the following has occurred:

- Regional travel demand model improvements implemented by the Chicago Metropolitan Agency for Planning (CMAP), formerly the Chicago Area Transportation Study (CATS).

- Preparation of 2020, 2030, and 2040 Long Range Transportation Plans for northeastern Illinois

- Conduct of CMAP 2007-2008 Travel Tracker Household Survey and new Census travel data.

- The rebuilding of the "Hillside Interchange" section of the I-290 Eisenhower Expressway.

1.3 Opportunity & Need for an I-290 Model Enhancement

Since the initial HOV feasibility study, additional considerations have come to light that affect the model application and planning assumptions. Regional socioeconomic forecasts of population, households, and employment have been updated during this period, and the forecasts horizon year is now 2040. The region's long-range transportation plan has similarly gone through several revisions and project traffic forecasts must take into account facilities and policies in the current GO TO 2040 Comprehensive Regional Plan[ii].

The CATS regional travel demand models were previously based on 1990 household travel survey,[iii] which was one of the basic sources of trip rates and distributions, along with the 1990 Census journey to work data[iv]. More current travel and socioeconomic data are now available. CMAP has recently completed a comprehensive household travel and activity survey for northeastern Illinois[v] that updates the 1990 effort. Data collection for the CMAP Travel Tracker survey took place between January 2007 and February 2008 with more than 10,500 households participating in the survey.

Additionally, the 2010 decennial census product provided other base data for the region. The long-form household sample portion of the decennial census, which collected journey to work and other detailed household and population characteristics, is no longer part of the 2010 and future decennial censuses. Long-form data are now continuously collected by the Census Bureau through the American Community Survey[vi] (ACS), which annually samples approximately three million households nationally. Although the annual sample of households for the ACS is far smaller than the number of households that previously received the long-form in the decennial census, roughly comparable quality data can be obtained by combining multiple years of the ACS.

The travel demand models used for the traffic forecasts in the initial feasibility made use of regional coded highway networks and region-wide traffic analysis zones maintained

by CMAP. These regional coded highway networks exclude most local streets. A further abstraction is the CMAP schematic coding of intersections and interchanges to reduce labor intensive data entry. Evaluation of the traffic estimates from these studies indicated that a more detailed analysis of corridor traffic was desirable both to improve the model's sensitivity to corridor improvements and to understand the effects of congested operating conditions.

The needs of the current I-290 Study, the availability of CMAP's model sets and expertise, and new sources of household and trip making data combined to provide the framework for the I-290 model adaptation and update. In keeping with the congruence with CMAP planning and travel modeling activities, the base year for the I-290 study is 2010. This memo reports on the establishment and validation of the 2010 base year. In general, model validation serves two key purposes:

- Establishes a model scenario in the current year (2010) that matches observed traffic conditions. The major observed elements are IDOT Average Annual Daily Traffic (AADT), peak period traffic and peak speeds. While the focus is the study corridor, the base year validation also shows that the travel model is replicating current traffic levels throughout the region. For example, in a validated I-290 model, interstate facilities throughout the region will have modeled traffic close to the observed values.

- Prepares a solid foundation for a future base year. Once a validated current year travel model is in place, it is understood that the socioeconomic inputs, model steps and parameters are working correctly and that future base and alternative scenarios will have an accurate starting point.

The 2010 validation has been completed. The 2040 base year was prepared and compared to the 2010. 2040 alternatives in the Study Area were then developed and tested. It is important to note that the alternatives evaluation focuses on relative differences, rather than absolute numbers; the 2040 alternatives are compared to the 2040 base.

1.4 Continuous I-290 Model Improvement

In the years between 2010 and 2015, the I-290 Travel Model received continuous enhancement. Much of this enhancement was related to evolving requirements for model components, such as tolling, HOV (High Occupancy Vehicle) and HOT (High Occupancy Toll) lanes model alternatives and reporting protocol. Other enhancements are due to the availability of new data, such as the 2010 and 2040 Market–Based socioeconomic forecasts as input to the I-290 model. In 2013-2014, the I-290 travel models were prepared using all enhancements available to the models. This report will present and explain the enhancements.

2.0 Model Preparation

2.1 Introduction

The I-290 travel model preparation involved two major areas. The first was the preparation of the input files, both geographic (network) and data related (socioeconomic data). The second key area was composed of changes to the four-step model structure. This section will address the preparation of the input files to the model. All preparation steps and four-step model changes were done to enhance the capability of the model to analyze I-290 scenarios.

The philosophy of the I-290 model can be summarized by the following points:

- **Fidelity** to the CMAP models – The goal of the current I-290 model update process is to adapt and utilize I-290 Study socioeconomic forecasts and travel demand model for the purpose of studying the traffic on the I-290 corridor between west of Mannheim Road to just west of the Jane Byrne Interchange.

- **Detailed I-290 Subarea** – Given that the Study Area encompasses the I-290 facility, but also the parallel roadways such as Roosevelt Road and Madison/ Washington Streets, it was necessary to build a detailed network within the Study Area. The CMAP representational highway network was enhanced by preparing a ground-truthed articulated network of I-290. This task involved a process called "conflation" in which the CMAP model highway segments and attribute information were transferred to a highly accurate Geographic Information System (GIS) data layer. As an example, the complex ramping configurations on the I-290 interchanges were added to the starting point CMAP network so that the true distance and intersection geometry could be captured. This detailed network editing included I-290 highway centerline conflation, ramp placement and directionality, and the confirmation of the number of mainline and slip lanes on the facility. The placement of centroid connector links was also revisited as part of the network editing.

- **Income and Auto Occupancy** – Where it is conceptually required, major new modules were added to the CMAP models. The most important one was the stratification of low and high income workers within the Home-Based Work (HBW) trip distribution and mode split models. The low/high income categories are retained through the trip table estimation and produce Single Occupancy Vehicle (SOV), High Occupancy Vehicle (HOV2 and HOV3+) home to work tables, each containing some low and some high income workers.

- **Focus on Efficiency and Comparability** – The regional model with all updates and revisions will be run for the 2010 base, 2040 No Build and 2040 "generalized" build

cases in the full model iteration mode to establish model outputs that are very highly converged.

- **Sensitivity Testing** – The overall reason for building the model is to test alternatives in the I-290 transportation corridor. Sensitivity tests were conducted including:

  – Identification of Regional Users – Select link analysis of representative link segments on I-290 and the parallel arterials by direction by time of day for truck and passenger vehicle were conducted.

  – Estimation of Transit Use – The 2040 RTP (conformity/fiscally constrained) transit network was used for the 2040 No Build case and was the starting point for transit use analysis. Transit measures will include mode split trip reporting of the regional impacts of potential major transit alternatives in the corridor.

  – Investigation of travel model Level of Service Assumptions – Investigation into the Volume Delay Functions for use in the model to represent each of the eight time periods in the model by facility was conducted.

2.2 Traffic Analysis Zones

The CMAP traffic analysis zone system was used directly in the I-290 corridor. Figure 2-1 shows this zone system with the Study Area highlighted. There are a total of 1,944 zones plus seventeen external points of entry located on major roadways at the border of the region where long distance and through traffic can enter and leave the region.

Figure 2-1. CMAP Traffic Analysis Zone System

2.3 I-290 Coded Highway Network

2.3.1 Background on Highway Coding

The travel model required highway network refinements in the expanded Study Area so that sufficient detail could be captured in the model traffic assignment result. These refinements added a local street network to the existing network so that it is possible to better evaluate traffic on the frontage roads and parallel local streets in the Study Area.

Links in the network are typically only coded between nodes that correspond to intersections and ramp junctions. While most intersections are accurately placed, ramp junction nodes are often located for ease of representation. Shape point nodes are rarely used to improve coded roadway alignments. As a result, maps of the coded network are not geographically accurate, which increases the effort required to interpret model results and prepare meaningful exhibits.

The modeling of 2040 alternatives, such as managed lanes within the Eisenhower Expressway corridor, increases the complexity of the network coding since these lanes must be restricted to certain classes of vehicles. They may also function differently depending on the time of day, with different peak and off-peak vehicle prohibitions or lane configurations, for example. These facilities also may serve a more limited set of

traffic movements than the general purpose lanes. The coded representation of special and general purpose lanes, as well as their points of access, must closely resemble the actual facility in order to ensure that the modeled version functions as designed.

As a first step, two tiers of corridor zones – one on either side of the expressway – were identified as areas warranting more detailed network coding. North and south boundaries for these two tiers of corridor zones are two arterial streets paralleling the expressway, Madison Street to the north and Roosevelt Road to the south. The east-west limits of the detailed coding extended from the Chicago central area to just west of Tri-State Tollway (I-294). Locations of local streets and frontage roads for the detailed network coding were obtained from the street network portion of the 2006 Census Topologically Integrated Geographic Encoding and Referencing system (TIGER) line files[vii]. Node numbers greater than the highest node numbers in the regional network were assigned to intersections in the TIGER network files. Network link files are customarily in a "from node" to "to node" format, unlike the TIGER network links. To create a network-like link file from the TIGER street segments, intersection node coordinates were matched against street segment endpoints and "from nodes" and "to nodes' transferred to the street segment file. The resulting network link file contained a link's defining node numbers and the distance along the link.

Nodes and links in the CMAP regional network within the detailed network area were deleted. TIGER source nodes and links were then combined with the remaining regional links and nodes to form I-290 project network files. Remaining cleanup of the network files required manual coding using transportation modeling software.

- The detailed TIGER network was stitched into the regional network at the boundaries of the detailed coding.
- Zone centroid nodes plus access links to connect centroids with the highway network were added for the new zones in the I-290 corridor.
- Eisenhower links and expressway-local street ramps were manually adjusted to more faithfully represent the actual facilities' alignments.
- Link data items from the regional network, not including distance, were copied to corresponding links in the detailed network.
- Additional data sources , the Illinois Roadway Information System[viii] and air photos, were consulted to code data items for additional links.

Figure 2-2 shows the detailed network within the zones on either side of the Eisenhower Expressway. The figure also shows zone boundaries and the locations of zone centroid nodes. It is apparent from the figure that even with the smaller zones, the number of points where traffic may enter and leave the network is still limited compared to the detail obtained from the TIGER files.

Table 2-1 summarizes the coding of the different variable fields in the network node and link records. Variable names that are preceded by the symbol @ are variables that must be coded in addition to the standard variables anticipated by the EMME/3[ix] travel demand modeling software. Assignment of vehicle trips to the coded highway network is covered in a later section. The EMME/3 macros were changed to allow highway segments to serve High Occupancy Vehicles (HOVs) alone in preparation for the alternative testing in the 2040 models. The link volume delay functions were revisited as part of the I-290 conversion although they did not differ from the original CMAP coding protocol. And finally, the CMAP Travel Tracker 2008 survey allowed for the re-estimation of the factors that allocate daily vehicle trips to time periods within a day. The issue of the volume delay function to be used for the High Occupancy Vehicle (HOV) and High Occupancy Toll (HOT) facilities will be addressed prior to the alternatives testing when travel times in the Study Area will be an important focus.

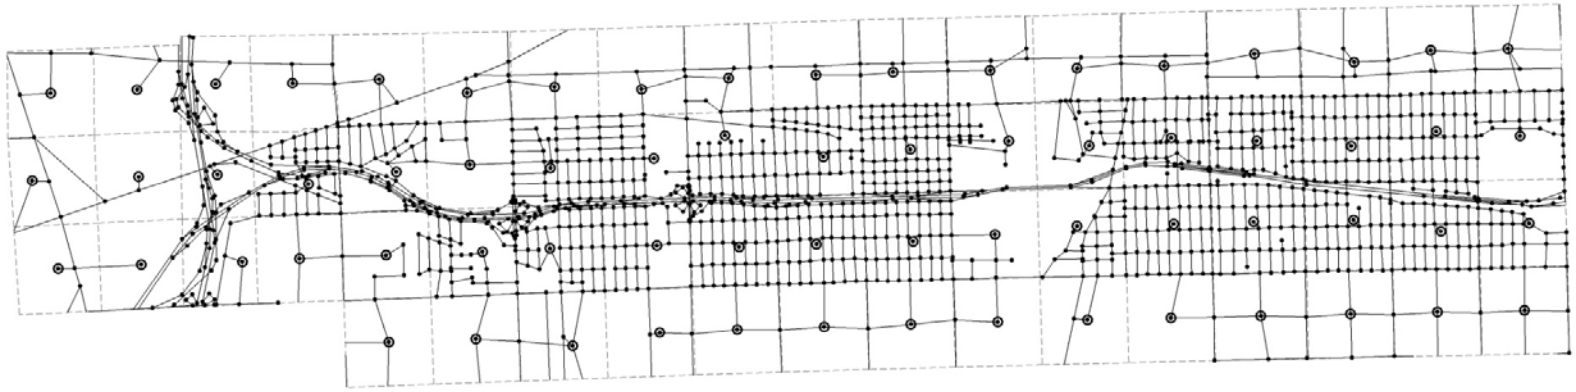

Table 2-1. Coded Variables in I-290 Network

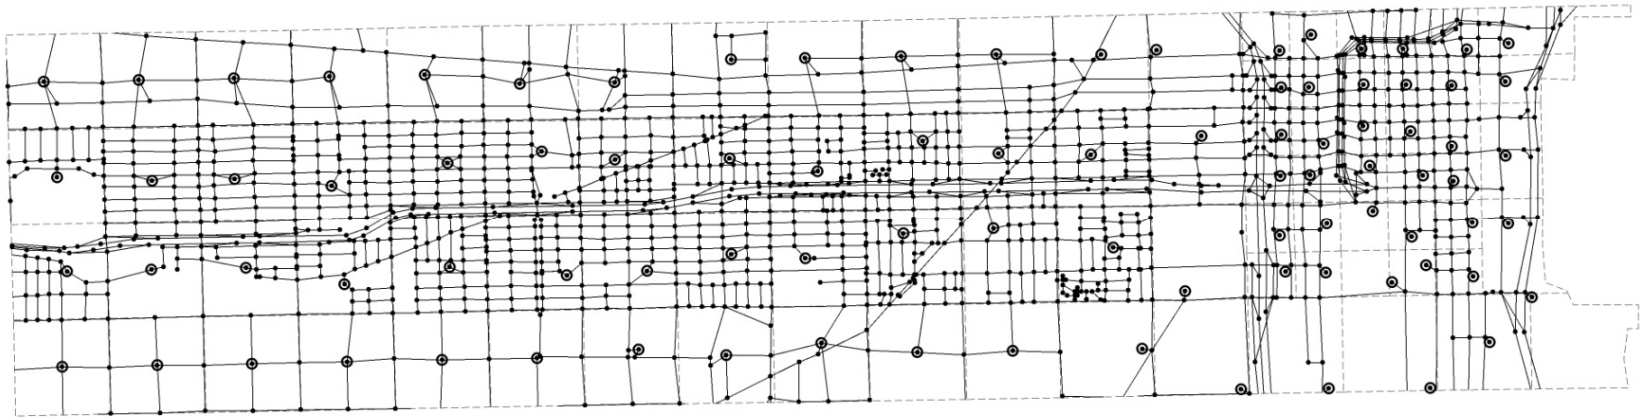
(I-290 Project Specific Coding in Boldface)



Node Variables	Description
@zone	**I-290 zone where node is located**
@atypej	Area type of I-290 zone
	1 = inside Chicago CBD (zones 1-47)
	2 = inside Chicago Central Area (zones 48-77)
	3 = inside remainder of Chicago
	4 = inside inner suburbs where the Chicago major and minor arterial street grid is continued
	5 = inside remainder of Chicago urbanized area
	6 = inside Indiana urbanized area
	7 = inside remaining Illinois suburban urbanized areas (Joliet, McHenry, etc.)
	8 = inside remaining Indiana suburban urbanized areas
	9 = inside remaining northeastern Illinois urban area
	10 = rural
	11=external area covered by Kenosha, Walworth, Racine, Boone, Winnebago, DeKalb, Ogle, Lee, LaSalle, Grundy, Kankakee, Porter, and LaPorte counties.
	12 = area of detailed network within I-290 corridor
	99 = points of entry into region
Link Variables	
mod	Modes permitted on link
	A = Generalized auto
	S = Single occupant auto
	H = High occupancy vehicle
	T = General truck
	b = B plate truck
	l = Light truck
	m = Medium truck
	h = heavy truck
lan	Number of driving lanes
vdf	1 = arterial street
	2 = freeway
	3 = freeway/expressway ramp from/to arterial street
	4 = expressway
	5 = freeway/expressway to freeway/expressway ramp
	6 = auto access to network
	7 = link where toll is paid
	8 = metered expressway entrance ramp
	9 = collector-distributor and local street links in I-290 corridor detailed network
typ	1 = default
	10 = POE connector
	88 = collector-distributor links in I-290 corridor detailed network
	99 = local street links in I-290 corridor detailed network
@speed	link free speed or speed limit from CATS/CMAP network
@parkl	number of parking lanes on link from CATS/CMAP network
@width	average lane width in feet

Figure 2-2. Detailed Network Coding in the I-290 Corridor

Eastern Portion from Austin Avenue (6000 West) to Lakefront

Western Portion from Eastern DuPage County to Central Avenue (5600 West)

Zone Border

2.3.2 Decision Rules for Highway Coding

The network coding prepared for the I-290 Study followed these guidelines:

- Provide adequate highway detail to capture movement on both I-290 and the parallel roadways. Include the capability to reflect interstate-to-interstate movements that are rational path choices for I-290 travelers.

- Provide network detail at one level below the desired analysis level of detail. Previous studies in the corridor have shown that network detail within a wide band of influence in the I-290 study corridor will be helpful in alternatives analysis.

- Build a highly detailed I-290 study network with all interchanges, merges and lane configurations matching the actual physical facility.

- Within the focused zone area, plus a one mile buffer, identify the locations for and code multiple centroid connectors.

- Prepare for a 2040 Baseline network. This network will not include any capacity enhancements on I-290, although it does include 2040 Regional Transportation Plan highway and major transit elements outside of the Study Area.

2.4 Socioeconomic Data

The socioeconomic data used for the I-290 study are Market-Based socioeconomic forecasts developed by The al Chalabi Group for the I-290 study.[x] Table 2-2 shows the totals for households and employment for 2010 that are based on 2010 Census data.

Table 2-2. Socioeconomic Forecast Totals for 2010

County	Households		Employment	
	# of Households	% of Regional	# of Workers	% of Regional
Cook	1,966,343	64%	3,125,691	64%
DuPage	337,132	11%	689,725	14%
Will	225,259	7%	252,316	5%
Lake	241,709	8%	428,851	9%
Kane	170,484	6%	257,348	5%
McHenry	109,200	4%	134,820	3%
Kendall	38,021	1%	29,806	1%
Six County Subtotal	**3,088,148**	**100%**	**4,918,557**	**100%**
All Other Counties*	754,313		754,839	
Grand Total	3,842,461		5,673,396	

Source: ACG I-290 Build & No Build Socioeconomic Report & Forecasting 06-2014

Table 2-2 shows over 3 million households and over 4.9 million workers for 2010 in the six county area. 64 percent of these households and employment lie in Cook County. DuPage County contains 11 percent of the regional households and 14 percent of the employment.

3.0 Travel Model Enhancements

3.1 Need for the Model Enhancements

The zonal and network disaggregation discussed in **Section 2** were conducted in parallel to the travel model enhancement work. The travel model enhancement was done at each level of the CMAP four-step model: (1) trip generation, (2) trip distribution, (3) mode choice, and (4) traffic assignment. Added to the core capabilities of the adapted CMAP model were the capability to model and analyze High Occupancy Vehicle (HOV) lanes, High Occupancy Toll (HOT) lanes, and toll lanes. Additionally, a battery of post-processing modules was built to provide full reporting capability for the I-290 custom model results. These included the means of summarizing all auto modes, truck results, and corridor specific summaries such as person through-put for auto and transit.

3.2 Household Person Trip Generation Model

The CMAP household trip generation model initially used for the I-290 work was obtained from CMAP in 2009. Only minor changes to this version of the model were completed as part of the first round of the I-290 project. The most significant enhancement was the option to create a file of estimated household vehicle ownership levels by the subzones that are used by the trip generation model.

For background, the 2009 updated CMAP household person trip generation model has the following features:

- Trip generation rates for persons residing in households are estimated with trip data from the 2007-2008 CMAP household travel survey.
- Model inputs can readily be updated with ongoing ACS data.
- A synthetic four dimension (adults-workers-children-income quartile) distribution of households into 224 categories is estimated for every trip generation sub-zone.
- Trip end estimates in detailed trip categories can be output including home-work trips by low and high income workers.
- Attraction allocation, household vehicle ownership, and non-motorized sub-models are revised and re-estimated with 2007-2008 household travel survey data.

The sequence of travel demand models for the I-290 project includes a mode choice model that allocates person trips into person trips by drive alone private vehicle, two persons ride-sharing, and three or more persons carpooling. The sub-mode choice model for private vehicles includes independent variables for the proportions of households within a zone at different levels of vehicle ownership. Since the household vehicle ownership sub-model in the CMAP trip generation model estimates these proportions, the same values of household vehicle ownership should be used in both trip generation and mode choice for internal consistency.

An option was incorporated into the trip generation code to retain the household vehicle ownership estimates for later use in mode choice. The fixed format for this file is listed in Table 3-1. Low income workers are defined as workers with below median regional earnings and high income workers have above median earnings.

Table 3-1. Household Vehicle Ownership File

Variable	Location
I-290 Zone	1-5
Households with One or More Low Income Workers	
Fraction of Households without Vehicles	6-17 (12.4)
Fraction of Households with One Vehicle	18-29 (12.4)
Fraction of Households with Two or More Vehicles	30-41 (12.4)
Households with One or More High Income Workers	
Fraction of Households without Vehicles	42-53 (12.4)
Fraction of Households with One Vehicle	54-65 (12.4)
Fraction of Households with Two or More Vehicles	66-77 (12.4)

A keyword was added to the program control file to optionally create the household vehicle ownership file. The **&PARAM** and **&END** statements identify the beginning and end of the **NAMELIST** input file that now includes the following keyword variables.

1. **TITLE**: An 80 character name identifying the model run enclosed in single quotes.

2. **SUBZONES**: Trip generation sub-zones in the Study Area.

3. **PUMA5**: Five percent sample Public Use Microdata Areas in the modeled Study Area.

4. **PUMA1**: One percent sample Public Use Microdata Areas in the modeled Study Area.

5. **ZONES**: Zones used in the remaining CMAP models for trip distribution (linking of trip ends into trips between zones), mode choice (allocation of trips to travel modes), and assignment (allocation of trips to highway and transit routes).

6. **COUNTIES**: Counties in the Study Area.

7. **PUMA_TG**: A true/false variable that defaults to false. When true the model's logic includes an optional subroutine that prepares an updated (future) four-way cross-tabulation of households within sub-zones. This new table is based upon (future) large area average household characteristics and the initial (base year) cross-tabulated household table.

8. **SAVE_FILE**: A true/false variable that defaults to false and causes all intermediate program files to be retained after the model run is completed.

9. **EXP_TTYPE**: A true/false variable that defaults to false. When true, all files and reports include forty-nine trip types based upon trip purposes in the CMAP household travel survey. When false, files and reports have the eleven trip types in the current CMAP trip generation.

10. **MODE_CHOICE**: A true/false variable that defaults to false. The optional household vehicle ownership file (Table 2) is created when keyword is true.

11. **IN_EMPFACT**: Employment in Indiana is multiplied by this factor, which defaults to 1.00. This variable and the following one for Wisconsin are included to offset possible systematic differences in employment definitions and estimation methods between CMAP and neighboring MPOs.

12. **WI_EMPFACT:** Employment in Wisconsin is factored by this value that defaults to 1.00.

In 2009-2010, Parsons Brinckerhoff staff was asked by CMAP to prepare enhancements to the Trip Generation program including:

- Updating the base year trip generation model inputs to 2010 with Census 2010 Summary File 1 small area population data and 2005-2009 ACS and ACS PUMS.

- Re-estimating differential trip generation rates for members of senior and younger households from the CMAP household travel survey.

- Revising trip generation model code to incorporate age of householder.

- Preparing a utility program that creates a database with discrete records enumerating households by size, number of workers, income level, vehicles available to household, and age of householder from intermediate trip generation work files.

- Revising group quarters trip generation procedure to include university/college dorms and military facilities.

- Adjusting bias coefficients in household vehicle ownership and non-motorized trip generation sub-models as needed to reproduce observed 2010 levels.

The trip generation updates were utilized in the Round 2 and Round 3 of the I-290 model runs.

3.3 Trip Distribution

3.3.1 Pre-Distribution Transit Access Parameters

Transit access parameters stored in two legacy trip distribution input files (M01.dat and DISTR.dat) were reviewed and updated for both 2010 and 2040. These file inputs were prepared using spatial analysis with a Geographic Information System (GIS) tool.

3.3.2 Pre-Distribution Travel Cost Model

The next model in the sequence of CMAP regional travel models estimates the highway and transit costs for trips between zones for use by the agency's trip distribution model. Costs are here calculated as in the CMAP mode choice model and the pre-distribution code is largely the same as the mode choice model code.

The overriding objective for revisiting this model in the I-290 project was to make all cost calculations in the model consistent with current, or near current, regional conditions. To this end, cost parameters that are model control variables and input files containing data used in the model's cost calculations were reviewed and updated.

The pre-distribution model reads data directly from an EMME/3 databank, a large data file that contains all network and zone data processed by the EMME/3 travel modeling software. A few minor changes in the code were required to reflect the naming of the databank as EMMEBANK by the most recent version of the EMME/3 software.

Home-Work Control Variables

Table 3-2 lists the control variables for trips between home productions and work attractions. These variables are read into the pre-distribution model through five namelist variable lists, lists of control variables contained between an &NAME identifier before the list (&PARAM, &OPTION, &PROCESS, &SYSTEM, and &TABNUM) and an &END at the end of the list. The table includes the variable values in the current CMAP

model setup for regional planning and the values used in the I-290 project plus a brief rationale for any adjustment of the CMAP values.

The coefficients in the mode choice model date from the original model estimation based on 1970 travel data. In particular, the coefficients for travel costs reflect 1970 dollar values. Since costs in the I-290 project are in current dollars, these coefficients needed to be adjusted. The Historical Consumer Price Index for all Urban Consumers[xi] indicates that a 1970 dollar would be worth $5.55 in current dollars and the cost coefficients were reduced accordingly.

Table 3-2. Control Variables In & PARAM Namelist for Home-Work Trips

Variable	Description	CMAP Regional Planning	Project	Reason for Change
ZONES	Highest zone number, must be less than or equal to EMMEBANK	1944	2233	Internal zones for I-290 project
CBDZON	CBD zone numbers (maximum of 200 zones)	1-77	1-77	I-290 project zones defined as Chicago central area
RNSEED	Random number seed (an integer value between 0 and 9999 with 0 implying a random value)	1934	1934	Arbitrary integer value set to allow comparison between model runs
COEFF1	Six coefficients in mode choice model to weight cost components for trips with destinations not in CBD	1. 0.0186 (Auto or transit line-haul in-vehicle time in minutes)	1. 0.0186	1. CMAP historical value
		2. 0.0072 (Auto line-haul costs or transit line-haul and access/egress costs in cents)	2. 0.00130	2. CMAP value factored by 0.18 (2008 to 1970 Urban Consumers' Price Index)
		3. 0.0584 (Auto walk time to/from parking or transit access/egress in-vehicle time in minutes)	3. 0.0584	3. CMAP historical value
		4. -2.000 (Transit bias)	4. 0.0	4. Transit bias not included in costs
		5. 0.0399 (Transit line-haul and access/egress out-of-vehicle time in minutes)	5. 0.0399	5. CMAP historical value
		6. 0.0811 (Half headway of first transit line-haul service boarded in minutes)	6. 0.0811	6. CMAP historical value
COEFF2	Six coefficients in mode choice model to weight cost components for trips with destinations in CBD	1. 0.0159 (Auto or transit line-haul in-vehicle time in minutes)	1. 0.0159	1. CMAP historical value
		2. 0.0085 (Auto line-haul costs or transit line-haul and access/egress costs in cents)	2. 0.00153	2. CMAP value factored by 0.18 (2008 to 1970 Urban Consumers' Price Index)
		3. 0.0486 (Auto walk time to/from parking or transit access/egress in-vehicle time in minutes)	3. 0.0486	3. CMAP historical value
		4. 0.0 (Transit bias)	4. 0.0	4. Transit bias not included in costs
		5. 0.0290 (Transit line-haul and access/egress out-of-vehicle time in minutes)	5. 0.0290	5. CMAP historical value
		6. 0.0173 (Half headway of first transit line-haul service boarded in minutes)	6. 0.0173	6. CMAP historical value

Table 3-2. Control Variables in &PARAM Namelist for Home-Work Trips (continued)

Control Variable	Description	CMAP Regional Planning	I-290 Project	Reason for Change
APC	Four daily parking costs for work locations in the region in cents	1. 400 (Chicago central area)	1. 800	1. The balance of the central area outside the zones covered by the CBD parking sub-model. Set to approximately half the on-street rate to reflect free employee parking.
		2. 100 (Balance of Chicago)	2. 100	2. Reflects mostly free employee parking outside the central area
		3. 100 (Dense suburban)	3. 200	3. Approximately half the on-street rate in business districts in dense suburban area
		4. 0 (Low density suburban)	4. 0	4. Generally free employee parking
WFA	Four average walking times from parked auto to workplace in minutes	1. 5 (Chicago central area)	1. 5	1. Default value for the balance of the central area outside the zones covered by the CBD parking sub-model.
		2. 3 (Balance of Chicago)	2. 3	
		3. 3 (Dense suburban)	3. 3	
		4. 3 (Low density suburban)	4. 3	
PRKZON	Zone numbers covered by CBD parking sub-model (maximum of 200 zones)	15-18,	2-7,	Determined by the availability of off-street parking rate data
		20-30,	9-30,	
		32-36,	32-36,	
		39, 40	39-41,	
			45, 47,	
			55-57	
ITER	Number of trips simulated between zone pairs to produce average cost values	10	100	Faster processing speeds allow far more trips to be simulated in acceptable times

Table 3-3. Control Variables in &PROCESS Namelist for Home-Work Trips

Control Variable	Description	CMAP Regional Planning	I-290 Project	Reason for Change
PZOI	Production/origin zones to be processed	1-1944	1-2233	More I-290 zones due to detailed zones in corridor
QZOI	Attraction/destination zones to be processed	1-1944	1-2233	

Table 3-4. Control Variables in &Option Namelist for Home-Work Trips

Control Variable	Description	CMAP Regional Planning	I-290 Project	Reason for Change
HW	Indicates home productions and work attractions are simulated	TRUE	TRUE	
HNW	Indicates home productions and non-work attractions are simulated	FALSE	FALSE	
OTH	Indicates origins and destinations without a home or work trip end are simulated	FALSE	FALSE	
ASM_AREA	Indicates parameters that control the simulation of distance from trip end to line-haul transit service are input by area type (Chicago central area, balance of Chicago, dense suburban sparse suburban)	FALSE	FALSE	
ASM_ZONES	Indicates parameters that control the simulation of distance from trip end to line-haul transit service are input by zone (DISTR input file)	FALSE (Note: regional defaults are used when both ASM_AREA and ASM_ZONES are false, see discussion of DISTR input file)	TRUE	New zone distance parameters estimated for I-290 zone system, current rail transit and commuter rail stations, existing CTA bus service, and PACE regional and feeder bus.
INCOST	Indicates that unit modal travel costs are input by area type and not set to program defaults	TRUE (Note: see discussion of M023 input file for values)	TRUE	Modal travel costs revised to approximate current values in M023 input file
TRACE	Indicates that extensive intermediate output is desired for program debugging	FALSE	FALSE	Used to check program calculations

Table 3-5. Control Variable in &SYSTEM Namelist for Home-Work Trips

Control Variable	Description	CMAP Regional Planning	I-290 Project	Reason for Change
SPDWLK	Average walking speed in tenths of a mile per hour	30	30	
SPEEDS	Four average auto speeds in miles per hour followed by four average bus speeds for use in the access/egress	1. 7 (Auto in Chicago central area)	1. 7	
		2. 15 (Auto in balance of Chicago)	2. 15	
		3. 20 (Auto in dense suburban)	3. 20	
		4. 30 (Auto in low density suburban)	4. 30	
		5. 5 (Bus in Chicago central area)	5. 5	
		6. 10 (Bus in balance of Chicago)	6. 10	
		7. 12 (Bus in dense suburban)	7. 12	
		8. 17 (Bus in low density suburban)	8. 17	
DRVOT	Value of time for auto drivers in cents	60	20	I-290 project value is one-half the 2008
AFC1	Auto fixed costs for driver in cents per trip	0	0	Auto fixed costs not used in cost estimation
AFC2	Auto fixed costs for auto passenger in cents per trip	0	0	Auto fixed costs not used in cost estimation
W2PNR	Walk time to station platform from park and ride lot in minutes	3	3	
DISCNT	Discount factor to bring costs to 1970 dollars,	0.3	1	Costs are expressed in current dollars

Table 3-6. Control Variables in &TABNUM Namelist for Home-Work Trips

Control Variable	Description	I-290 Project
TABLE_FMD	EMMEBANK input table number for first transit mode boarded	Table numbers depend upon data preparation in EMME software
TABLE_LMD	EMMEBANK input table number for last transit mode boarded	
TABLE_IVT	EMMEBANK input table number for transit in-vehicle time	
TABLE_OVT	EMMEBANK input table number for transit out-of-vehicle time	
TABLE_HWAY	EMMEBANK input table number for headway of first transit line boarded	
TABLE_PMD	EMMEBANK input table number for priority mode	
TABLE_FARE	EMMEBANK input table number for transit fares paid	
TABLE_HTIME	EMMEBANK input table number for highway travel time	
TABLE_HDIST	EMMEBANK input table number for highway distance traveled time	
TABLE_AUTIL	EMMEBANK output table number for auto general cost	
TABLE_TUTIL	EMMEBANK output table number for transit general cost	

3.4 Transit Networks and Model Approach

The Study Area features several important rail and bus transit services with the CTA's Blue Line (O'Hare-Forest Park) of the highest importance. Capturing the transit mode is integral to getting travel right in the I-290 corridor. To this end the CMAP transit models were expanded and enhanced. The following changes were made with the goal of validating the I-290 corridor for transit:

- Daily transit trips were stratified by trip purpose including two Home-Based Work income classifications: Home-Other and Non-Home Based.
- Transit skims were set up defining "first mode" and "priority mode" to inform the transit trip processing step below.
- Transit trip start and endpoint were coded with X-Y coordinates to utilize the EMME function that steps aways from "centroid" start and end point assumptions and instead uses point location. Walk and drive access were established for transit trips by transit mode. Metra, CTA rail and bus were established as the transit modes in the region.

- Transit assignment approach, including headway preparation, was established. The assigned lines can be summarized by line and are also used as input to a set of transit post processing/reporting programs. These programs include I-290 corridor transit person miles and transit screen lines.

The transit procedure was written in a set of EMME macros and in customized data processing scripts so that it is automated and repeatable. The results of this transit effort allow analysts to quickly show the difference on the CTA Blue Line as well as commuter rail and bus in the I-290 corridor given the addition of an HOV, HOT or toll lane scenario. Transit plays a key role in the I-290 study due to its presence in the median of the facility and also due to the interplay between transit and HOV. Transit users are typically more readily influenced by the availability of HOV/HOT than are auto drivers.

3.5 Mode Choice Updates

3.5.1 Project Approach

The CMAP mode choice model was partly recalibrated for the I-290 study to reflect current travel costs and mode shares in the region. The calibration process started with the model coefficients that were estimated some years before by CATS, CMAP's predecessor agency, and currently used for agency planning projects. The cost coefficients were next adjusted so that costs could be expressed in current dollars, rather than 1970 dollars, the date of the survey used for the original model estimation. The Consumer Price Index for all Urban Consumers indicated that one 1970 dollar equaled approximately $5.50 in 2008-2009 dollars.

The first round of calibration effort consisted of adjusting bias constants so that resulting mode shares estimated by the model matched observed mode shares. Home-work coefficients were calibrated to observed data in the 2000 Census Transportation Planning Package, while home-other and non-home model coefficients were calibrated to data from the CMAP-Northwestern Indiana Regional Planning Commission 2007-2008 household travel survey. This work fitted the model to reflect that there are very long work trips to the Chicago central area.

3.5.2 Descriptions of Model Coefficients

1. **COEFF1:** Six model coefficients that control binary auto-transit mode shares for trips (home-work, home-non-work, and non-home) to non-CBD destinations.

    a. **COEFF1 (1):** Zone to zone **i**n-vehicle time on line-haul modes in minutes.

    b. **COEFF1(2):** Zone to zone auto operating costs or zone to zone line-haul transit fares plus costs to access/egress transit service in cents.

c. **COEFF1 (3):** In-vehicle time to access/egress transit in minutes.

d. **COEFF1 (4):** Transit bias constant. Although a negative number due to the negative sign associated with the variable in the transit cost (negative utility) calculation, it can be interpreted as the added inherent cost of selecting transit.

e. **COEFF1(5):** Zone to zone out-of-vehicle time accrued from the initial transit boarding to final alighting plus the out-of-vehicle time to access/egress transit except for the time spent waiting for the initial boarding due to service frequency (one-half headway) in minutes.

f. **COEFF1 (6):** One-half headway of first transit line boarded in minutes.

2. **COEFF2:** Six model coefficients as described above that control binary auto-transit mode shares for trips to non-CBD destinations.

3. **HOV_BIAS:** Two bias constants used in the submodel to allocate home-work person trips by auto into drive alone, two person shared ride, and three or more person carpool auto submodes for trips to non-CBD destinations.

   a. **HOV_BIAS (1):** Three or more persons carpool bias. The inherent added cost of selecting the three or more person carpool mode versus the two person shared ride mode. .

   b. **HOV_BIAS (2):** Shared ride (two or more persons) bias versus. The inherent added cost of shared ride modes as opposed to driving alone.

4. **HOV_CBDBIAS:** Two bias constants as described above for trips to CBD destinations.

3.5.3 Mode Choice Coefficients for Different Model Applications

The model can be run in six different modes depending on the trip purpose, use of the HOV submodel to allocate auto trips into occupancy level submodes, and segmentation home-work trips by earnings level.

1. Home-work trips for all workers

   a. Auto-transit binary choice

   b. Auto-transit binary choice with HOV submodel allocation

2. Home-work trips segmented by workers' earnings

   a. Auto-transit binary choice with HOV submodel allocation for low earnings (below regional median earnings) workers

b. Auto-transit binary choice with HOV submodel allocation for high earnings (above regional median earnings) workers

3. Auto-transit binary choice for home-non-work trips

4. Auto-transit binary choice for non-home trips

The following coefficients were calibrated during the preparatory work for modeling an HOV lane treatment as part of the reconstruction of the Eisenhower (I-290) Expressway.

Table 3-7. I-290 Project Mode Choice Coefficients for Home-Work Trips

	Auto-Transit Binary Choice	Auto-Transit Binary Choice with HOV Submodel	Low Earnings Auto-Transit Binary Choice with HOV Submodel	High Earnings Auto-Transit Binary Choice with HOV Submodel

3.6 Mode Choice – High Occupancy Vehicle Integration

3.6.1 Non-Work High Occupancy Vehicle Mode Share Estimation

In 2012, the needs of the I-290 model required a re-estimation of the existing CMAP mode choice model to better estimate the auto submodes - single occupant, two persons, or three or more persons per vehicle – for home-work travel. This focus on commuters' behavior was reasonable due to the fact that most home-work travel takes place in the congested peak period and high occupancy highway facilities are particularly intended for commuters' use. Also, non-work trips are often too short to make use of these HOV facilities.

Non-work auto occupancy was currently estimated using observed regional average values, but more detailed estimates were needed since non-work travel is more likely to contribute to congestion. Peak period travel conditions have steadily lengthened and now encroach upon the times of the day when substantial non-work travel occurs. This is particularly the case in the early hours of the evening peak period when both workers and non-workers are returning home.

The enhancement to the CMAP mode choice model estimated home-other and non-home trip auto occupancy. Given the availability of data, it was anticipated that the model would feature independent variables that include the characteristics of the household and trip length.

As part of the mode development, the state of the practice for non-work auto occupancy models was reviewed. A non-work HOV mode share estimation was estimated. Finally the I-290 mode choice model was revised to incorporate a non-work auto occupancy submodel.

3.6.2 Toll and Non-Toll Mode Choice

In 2012 it was determined that the CMAP/I-290 mode choice model contained a set of options for evaluating the effect of tolls on mode choice. These features of the model had never been tested, calibrated or validated. These existing options in the model were evaluated to make them a useful part of the CMAP standard model procedure. Staff assembled the base year networks with current vehicle tolls, developed a set of model calibration traffic counts for toll and non-toll regional facilities, revised the EMME macros to prepare separate paths and skim files for toll and non-toll networks, then ran the current version of the I-290 model on the base year network.

Estimation work was then conducted to evaluate the model run and adjust model calibration coefficients as necessary to best match toll and non-toll traffic count data. The revised mode choice toll component was calibrated and used directly in the I-290 work to capture accurately household income and trip length characteristics which improve results for pricing alternatives such as HOV and HOT.

3.7 Traffic Assignment

The CMAP and I-290 models use the EMME/3 standard traffic assignment which is a user-optimal equilibrium assignment with linear approximation (Frank and Wolfe). It is based on the assumption that each traveler chooses the path (or route) perceived as being the best; if there is a shorter path than the one being used, the traveler will choose it. At the equilibrium, no one can improve their travel time by changing paths. With the standard traffic assignment, up to 12 classes can be assigned simultaneously. For each class there are multiple choices for saving and storing the assignment results. For the I-290 effort the class specific volumes generated from the multi-class assignment on links are saved in link segment extra attributes keyed to the vehicle class**.** Table 3-9 lists the seven vehicle classes for the study.

Table 3-9. Vehicle Classes for Traffic Assignment

Number	Link Mode	Description	Extra Attribute Name from Assignment
1	H	High Occupancy Vehicle (2)	@hov2
2	H	High Occupancy Vehicle (3+)	@hov3
3	S	Single Occupancy Vehicle	@vauto
4	b	"B" Plate truck	@vbplt
5	l	Light Truck	@vlght
6	m	Medium Truck	@vmed
7	h	Heavy Truck	@vhevy

The most recent EMME/3 path-based assignment was utilized with each of the seven vehicle classes cited in Table 3-9 assigned using multi-class procedure by time period. The overall assignment approach allowed integration and analysis of HOV and HOT for 2 or for 3+ persons per vehicle. The path-based assignment also facilitated the saving of assignment results and paths for each time period. These path files allow quick review and analysis of individual assignment runs and are valuable for trouble-shooting model results.

3.8 Computational Enhancements

3.8.1 Model "Batch" Processing

The recalibration and validation steps implemented in the I-290 model conversion required that the structure of the EMME/3 batch file be revisited and revised. The batch program is designed so that a scenario is prepared after which eight time periods summing to a 24-hour day are assigned in turn. A two databank structure was established for the I-290 work:

1. **Simulation Bank** – the EMME/3 databank that is alternative specific and which holds the base network, eight time of day networks, reports from the model runs, and the zonal data.
2. **Archive Bank** - An archive or "hold" databank, also alternative specific, that captures the current times and trips by purpose and mode in matrix form from each of the five full model iterations.

In the production stage is was determined that separate databanks, copied from the final archived bank for each scenario, were valuable for processing the Transportation System Plan (TSP) reporting as well as the transit results after the .

3.8.2 Parallel (Multi-threaded) Standard Traffic Assignment

Revision of the EMME/3 macro approach also allowed a software innovation to be introduced. INRO's EMME/3 assignment called Parallel Standard Traffic Assignment is a multi-threaded implementation of the Standard Traffic Assignment with Fixed Demand that makes use of multiprocessor systems when available. It remains an implementation of the linear approximation algorithm (Frank and Wolfe) equilibrium assignment, hence the same convergence properties as the Standard Traffic Assignment, with the distinction that computing times can be reduced significantly when run on systems with multiple processors. The user is able to select how many threads will be used in the assignment, with each thread corresponding to dedicated use of one processor. This allows users to choose how many processors to dedicate to the parallel traffic assignment and provides the opportunity to leave processors for other concurrent computing needs if desired[xii]. The I-290 model application integrates calls to the multi-threaded EMME/3 module thus enhancing run time and efficiency.

Additional computational enhancements were built during the I-290 process. These included "Hot Starts" streamlining, simultaneous execution of time of day scenario runs, and transit trip assembly and assignment. As the EMME provided updates, staff installed them and integrated the new capabilities of each updated version in the I-290 model.

3.9 Model Post Processing

A library of EMME macro scripts was prepared to serve the model runs with a reporting stream allowing error investigation ("trouble-shooting") and monitoring to take place. The batch processing approach was written so that both base and future years could be run with a minimum of reporting file setup changes. Post processing and reporting of the eight time of day periods and the six vehicle types originally included:

- Calculation of average daily vehicle traffic from the sum of single occupancy vehicles, high occupancy vehicles, and four classes of trucks over the eight time periods.

- Calculation of the daily Vehicle Miles Traveled (VMT) for both auto and truck.
- Calculation of the daily Vehicle Hours Traveled (VHT) for both auto and truck.
- Mode split report that facilitates the summary of trips by purpose by auto mode (SOV, HOV2 and HOV3+) and transit.

The evolution of the I-290 model has required expanded reporting protocol. Chief among the expanded reporting is:

- Person throughput for SOV, HOV and transit (three points in the corridor).
- Expanded speed and congestion reports in peak periods.
- Detailed truck reporting, including congested truck miles and hours.
- Refinement of Access to jobs reporting.
- Enhanced transit reporting by mode, cutpoint and Study Area.

4.0 2010 Validation of the I-290 Model

4.1 Introduction

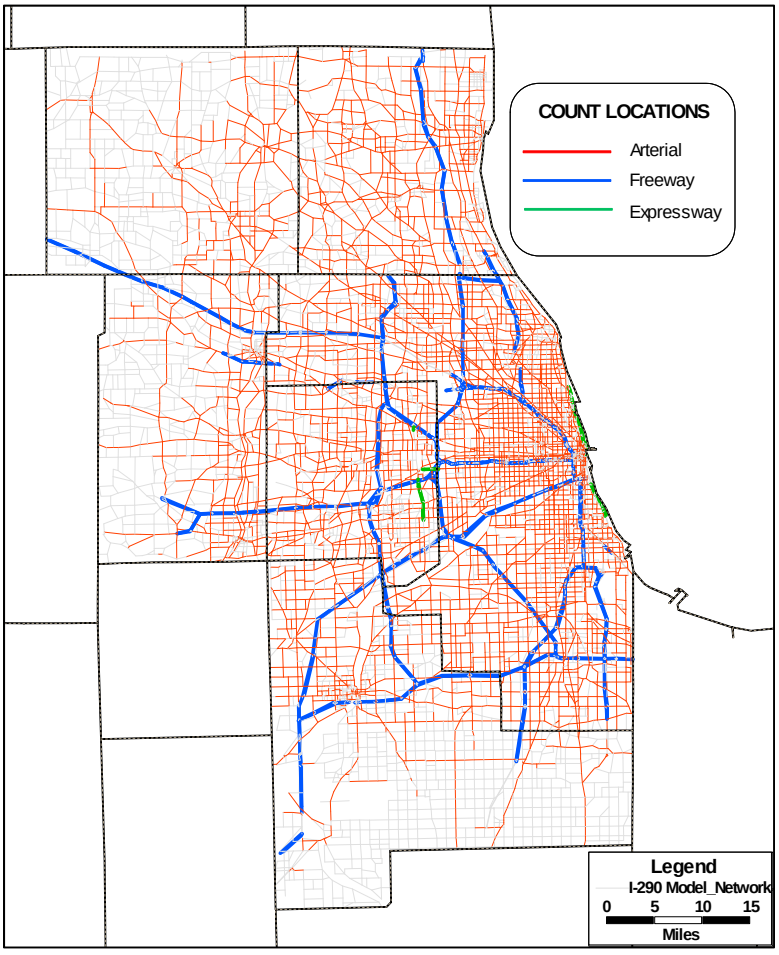
A review of the I-290 performance with the full set of revised 2010 inputs as well as the model enhancements was conducted. The intent of this section is to validate 2010 I-290 model for its use in 2040 alternatives analysis. The travel model validation topics reviewed were:

1. Regional Level Traffic Validation (Six-County)
2. Peak Period Traffic Validation
3. Volume/Capacity Ratios
4. I-290 Corridor Daily Traffic Validation

4.2 Regional Model Validation

The eight time periods established in the CMAP models are summed to a daily vehicle traffic total on each highway segment of the model. This estimated daily traffic can then be compared to observed traffic data (Average Annual Daily Traffic or AADT). There are eight time periods in the I-290 model, including an AM and PM peak. The peaks can also be compared to observed peak traffic, which is useful particularly in the I-290 corridor.

4.2.1 Observed Data



Observed data for the I-290 effort was obtained from CMAP with the ultimate source being the Illinois Department of Transportation[xiii] (IDOT). CMAP staff tabulates, geocodes, and updates the observed traffic data in EMME/3-ready format allowing the analyst to compare the counted links to the model output. Newly tabulated counts were available in 2015 for year 2010. For the I-290 project the count locations within the six county region were used. Over 10,400 link segments are counted in the CMAP model network, 62 percent of all link segments, as shown in Table 4-1. Of the arterial segments, 60 percent are counted. Of the freeway segments, 73 percent are counted. Figure 4-1 shows the locations of the CMAP observed data for the three main classes. Figure 4-2 shows a close-up of the I-290 corridor with count locations.

Table 4-1. Number of Count Locations by Class (Using VDF Function Group)

Link Type	Volume Delay Function	*Count Profile*		
		Counted Links	Total Links	% Counted
Arterial Street	1	8,901	14,732	60%
Freeway	2	732	997	73%
Freeway/expressway ramp from/to arterials	3	595	922	65%
Expressway	4	48	88	55%
Freeway/expressway to freeway/expressway ramp	5	106	147	72%
Link where toll is paid	7	83	109	76%
Total		**10,465**	**16,995**	**62%**

4.2.2 Regional Scale Validation Tests

As mentioned above, validation of the travel model traffic to observed conditions is an important part of establishing a base for alternatives testing. Validation has two levels:

- **Regional Validation** which shows that the model is working at reasonable levels throughout the entire metropolitan area and thus forms a stable platform for a study area such as the I-290.

- **Corridor Validation** which shows that the model is working at very close tolerances to the observed data in a study area and can replicate conditions for the daily as well as the peak periods in a study area.

Although absolute criteria for assessing the validity of all model systems cannot be precisely defined, a number of target values have been developed. Guidance on validation targets is provided by the Federal Highway Administration (FHWA)[xiv] as well as by state DOTs. Observed volumes should be checked by facility type both for the percent traffic difference and for the Root Mean Square Error (RMSE). Freeway and interstate segments should be within +/- 7 percent of the observed traffic. Less heavily traveled roadways have less stringent requirements on their fit to observed traffic. Given a reasonable regional validation result, the travel model is deemed a reliable tool for alternatives testing.

The following validation tests were performed on the I-290 Travel Model to test the daily traffic assignment:

- **All Links Observed and Modeled Traffic Volume Comparison** – This test, which compares the observed and the modeled traffic using observed and counted traffic, is presented by volume class.

- **All Links Percent Root Mean Square Error** – This test, which measures the difference between model volumes and observed traffic counts, is where the variability of the traffic counts is most evident. If the model fit were perfect, the percent root mean square error would be equal to zero. A Percent RMSE value of 35-50 is considered within normal limits. This test is also presented by volume class. Typically the higher volume ranges show lower PRMSE.

Table 4-2 presents the counted and modeled traffic stratified by volume class using one-way traffic. There are eleven volume classes; the lowest volume class covers all facilities with fewer than 10,000 AADT. The highest volume class is all facilities with 100,000 AADT or higher. Note that the percent difference between the observed and modeled ranges from -17 percent to 103 percent. This table shows that the smaller volume facilities do not perform particularly well; they show higher model traffic than observed, the result of including counts from numerous minor arterials in the model network. This difference is attributed to the fact that the arterials carry the traffic for many lower classification facilities which are not included in the model network. Note that the volume class with the poorest performance is composed of facilities carrying less than 10,000 ADT and that the ratio improves as the level of traffic measured grows. This differential is common in demand model results and is acceptable as long as the higher level roadways perform close to the observed levels. This table shows that higher volume facilities do generally operate within the travel model at very close to observed levels. This range of observed to estimated is -11 percent to +4 percent on facilities over 50,000 AADT. The Percent Root Mean Square Error shows that the variability of the model results is very small on these road segments. The total difference of all road segments over 10,000 AADT is 0 percent with a Percent RMSE of 35. PRMSE values in the 35-50 range are considered within the normal limits of MPO validation.

Table 4-2. Traffic Validation by Volume Class

Volume Range	AADT Range (one-way)	# of Records	Counted Traffic (AADT)	Modeled Traffic	Difference		Root Mean Square Error	Percent RMSE
					#	%		
1	0-10,000	17,635	69,716,375	141,354,381	71,638,006	103%	5,872	149
2	10,000-20,000	754	9,488,500	13,089,740	3,601,240	38%	10,440	83
3	20,000-30,000	214	5,213,000	4,586,896	(626,104)	-12%	13,697	56
4	30,000-40,000	130	4,453,700	4,353,668	(100,032)	-2%	15,984	47

5	40,000-50,000	105	4,769,350	3,980,848	(788,502)	-17%	19,796	44
6	50,000-60,000	89	4,957,450	4,899,383	(58,067)	-1%	13,677	25
7	60,000-70,000	114	7,447,200	7,193,090	(254,111)	-3%	13,530	21
8	70,000-80,000	103	7,770,150	6,918,280	(851,870)	-11%	14,618	19
9	80,000-90,000	91	7,766,450	7,216,112	(550,338)	-7%	13,762	16
10	90,000-100,000	64	6,026,750	5,705,078	(321,672)	-5%	12,869	14
11	over 100,000	47	5,329,100	5,539,495	210,395	4%	14,266	13
All		**19,347**	**132,939,125**	**204,843,595**	**71,904,470**	**54%**	**6,827**	**99**
Volume Range over 10,000 AADT		**1,711**	**63,221,650**	**63,482,588**	**260,938**	**0%**	**13,100**	**35**

Source: CMAP Highway Network Traffic Counts, Parsons Brinckerhoff, Inc. I-290 Model Run for 2010

In summary, regional model validation is a first step to determining if the travel model is a reasonable tool to use within a focused study area. Table 4-2 is consistent in the overestimation of traffic at the lower volume classes, which is expected. The regional numbers show very good results (PRMSE of 35) in the over 10,000 ADT facilities. This result is acceptable at a regional level, particularly if it can be shown that the model will operate at very close tolerances in the study area, for peak periods.

4.3 Peak Periods Traffic and Percentage of Daily

Since the peak periods are an important part of the traffic model for I-290 work, the AM and PM observed traffic to the model results were compared. Table 4-3 and Table 4-4 show the observed mainline traffic at six locations during the peak periods in the I-290 study corridor. Observed IDOT peak period definitions are as follows:

- Eastbound Traffic - one hour from 7 to 8 am and 4 to 5 pm
- Westbound traffic – one hour from 8 to 9 am and 4 to 5 pm

The I-290 traffic model peak hours were extracted and compared to the observed IDOT data.

Table 4-3. AM and PM Model and Observed Traffic on I-290 (Eastbound)

I-290 Facility		Observed (1 hour)		Modeled (1 hour)	
From	**To**	**AM Peak**	**PM Peak**	**AM Peak**	**PM Peak**
Mannheim	25th Avenue	5,340	5,240	6,490	6,530
25th Avenue	17th Avenue	5,430	5,330	6,400	6,315
9th Avenue	IL 171 (1st Avenue)	5,840	5,850	6,265	6,500
IL 171	Des Plaines Ave	6,240	6,510	6,010	6,170
Des Plaines	Harlem	6,100	6,240	5,850	5,715
Austin	Central	7,670	7,110	6,630	6,035
Laramie	Cicero	8,430	7,670	8,095	6,465

Source: IDOT 2010 Traffic Counts, Parsons Brinckerhoff, Inc. I-290 Model Run for 2010

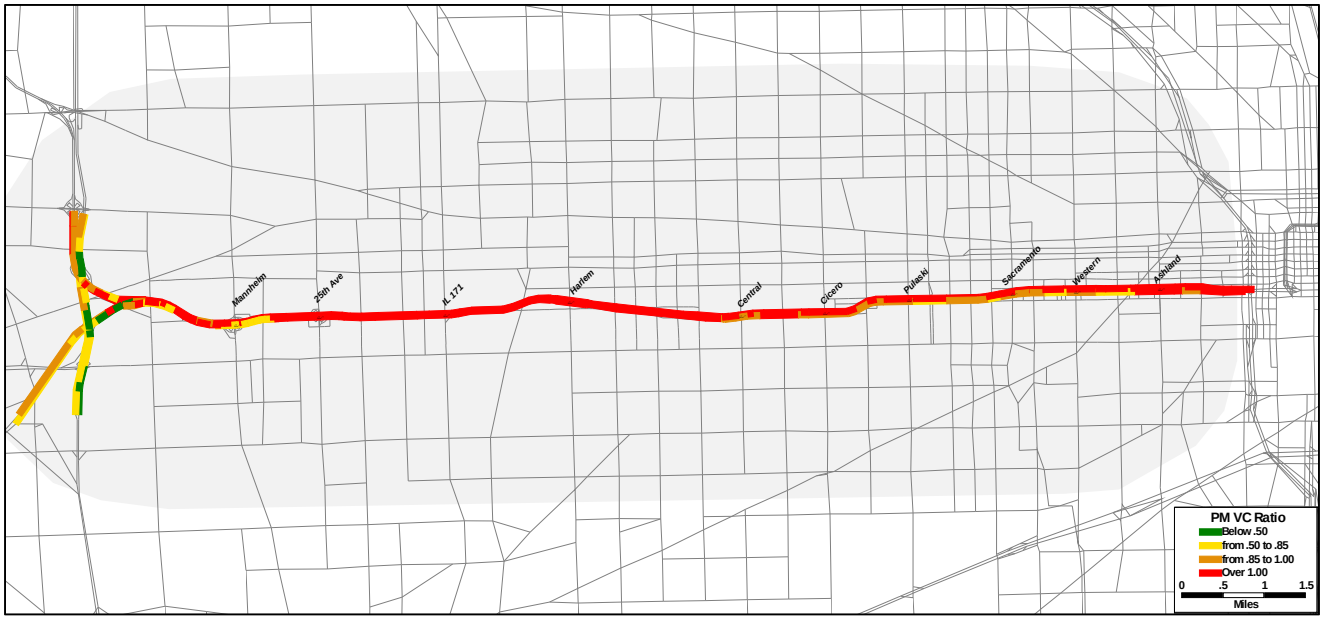
Table 4-4. AM and PM Model and Observed Traffic on I-290 (Westbound)

I-290 Facility		Observed (1 hour)		Modeled (1 hour)	
From	**To**	**AM Peak**	**PM Peak**	**AM Peak**	**PM Peak**
Mannheim	25th Avenue	7,130	6,790	6,225	6,360
25th Avenue	17th Avenue	6,980	6,700	6,220	6,445
9th Avenue	IL 171 91st Avenue)	6,570	6,560	6,315	6,405
IL 171	Des Plaines Ave	6,500	6,480	6,140	6,115
Des Plaines	Harlem	5,800	5,890	5,885	5,900
Austin	Central	5,740	6,410	6,205	6,790
Laramie	Cicero	6,100	6,650	6,585	8,235

Source: IDOT 2010 Traffic Counts, Parsons Brinckerhoff, Inc. I-290 Model Run for 2010

Table 4-3 and Table 4-4 show the following:

- Both observed and modeled traffic show very little directionality; both eastbound and westbound traffic flows are generally very close in magnitude in both the AM and PM peak.



- The volume of traffic produced by the I-290 model is commensurate to observed traffic levels on the I-290 facility for both the one-hour AM and PM peaks.

4.4 Peak Period Volume/Capacity Ratio

The volume to capacity ratio (V/C ratio) is defined as the ratio of traffic demand flow rate to capacity. In the CMAP models it may be calculated for each of the eight time periods and is calculated on each link segment of a traffic model. V/C is a planning tool used in this analysis to provide conceptual level views of congestion for the time periods

provided in the model. Each time period for the 2010 base was reviewed to demonstrate that the I-290 model was able to capture basic directionality and congestion via the V/C ratio. Figure 4-3 shows the V/C ratio in the PM peak for 2010. Note that I-290 shows PM congestion of over 1.00 in both directions.

Figure 4-3. Volume/Capacity Ratio for the PM Peak 2010

Source: Parsons Brinckerhoff, Inc. I-290 Model Run for 2010

4.5 I-290 Corridor

The last topic of validation is the performance of the I-290 daily traffic model in the study corridor. The performance of the model on a daily basis adds understanding of the overall validity of the model. Figure 4-4 is a snapshot of the daily model traffic for the I-290 2010 scenario. The summary attribute is total vehicles in vehicle equivalents. Note that the interstate facilities are heavily traveled, the daily facility directionality is balanced, and the traffic volumes, measured in vehicle equivalents, are in the range of 90,000 to 100,000 in each direction at most points in the I-290 study corridor.

Figure 4-4. 2010 I-290 Daily Traffic Estimate

Source: Parsons Brinckerhoff, Inc. I-290 Model Run for 2010

Table 4-5. I-290 Mainline Traffic Comparison (Observed vs. Modeled)

ID	I-290 Facility		AADT 2012	Model ADT 2010	Difference	
	From	To			#	%
1	W of Mannheim		187,700	208,174	20,474	11%
2	Mannheim	25th Ave	182,800	182,994	194	0%
3	E of 25th Avenue		182,200	182,882	682	0%
4	9th Avenue	IL 171	185,700	185,729	29	0%

15	Western	Damen	208,800	205,937	-2,863	-1%
16	Damen	Ashland	200,500	203,633	3,133	2%
17	Ashland	Racine	185,900	187,111	1,211	1%

	Total	**3,267,000**	**3,272,082**	**5,082**	**0%**

Source of AADT: IDOT Traffic Data, 2012, Parsons Brinckerhoff Model Run for 2010

Table 4-5 tabulates seventeen segments of the I-290 corridor comparing 2012 observed traffic counts to the results by segments in the study corridor from west of Mannheim to Racine. The observed data averages about 200,000 AADT throughout the corridor. Estimated (model ADT) difference values range from -5 percent to +5 percent different from the observed data, with the exception of the segment west of Mannheim. There is an overall 0 percent difference in the sum of the segments comparing estimated to observed.

4.6 Findings

It has been the intent of **Section 4** to present an overview of validation steps for the I-290 Travel Model demonstrating that it provides a reliable base replicating observed conditions at the regional and corridor level.

- The I-290 model enhancements steps which included major changes in trip rates by purpose, percentage of work trips of all trip purposes, trip distribution structure, average trip lengths, auto occupancy changes, and time of day percentages resulted in a model that replicated regional and I-290 corridor traffic. Based on a set of CMAP counts obtained from IDOT for 2012, the I-290 travel model is performing at a reasonable level compared to regional traffic flows. The ratio of observed to modeled traffic on regional interstates and freeways and the Percent Root Mean Square error are within normal limits for MPO validation.

- The AM and PM peak periods in the model produce traffic levels commensurate with the IDOT observed data.

- I-290 mainline traffic for 2010 averages slightly lower (0 percent) in the model than in the observed 2012 IDOT counts. Estimated (model ADT) difference values by segment range from -5 percent to +5 percent different from the observed data, with the exception of the segment west of Mannheim.

In summary, a detailed travel model customized for I-290 was developed, including constructing a detailed network. The use of recent household survey and other data to re-estimate selected parts of the CMAP models resulted in an updated model that was validated to 2010 then applied to the 2040 study year alternatives.

1.0 Introduction and Overview

The I-290 Study is among several recently-completed or in-progress transportation projects that have used a market-driven socio-economic forecast developed by ACG: The al Chalabi Group, Ltd. ACG's forecast methodology is similar to that which previously had been used by the regional planning agency, the Chicago Metropolitan Agency for Planning (CMAP), and its predecessor, the Northeastern Illinois Planning Commission (NIPC), until the development of the CMAP GO TO 2040 Comprehensive Regional Plan, in 2010. The CMAP GO TO 2040 Plan adopted a strict Policy-Based approach to forecasting.

This report documents the development of the Market-Driven forecasts that represent the I-290 No Build Scenario, which is described in Section 2.0. A comparison of the I-290 Market-Driven approach to the CMAP approach is presented in Section 3.0. This report then presents the I-290 Build forecast development in Section 4.0. An Epilogue is presented in Section 5.0 that describes the I-290 Forecasts in relation to the CMAP forecasts developed as part of the GO 2040 Comprehensive Regional Plan Update that was completed in 2014.

Year 2040 socio-economic forecasts were developed as part of the I-290 Study. Socio-economic forecasts, including population and employment forecasts, are used as input to the I-290 travel forecasting model. The I-290 travel forecasting model uses the socio-economic forecasts to estimate future traffic and transit usage for use in design, environmental, and financial analyses. The year 2040 was selected as the planning horizon for consistency with the region's metropolitan transportation plan. The metropolitan transportation plan is intended to guide public policy with respect to future infrastructure investment for the next 20+ years for the region. The metropolitan transportation plan is intended to identify an overall framework of major capital projects that are tested for air quality conformity and are within an assumed fiscally constrained scenario. The projects identified as part of the region's metropolitan transportation plan process, which include the proposed project, are consistent with plan goals and essentially represent placeholders that are subject to National Environmental Policy Act (NEPA) studies, including a rigorous analysis of alternatives. The metropolitan transportation plan does not, however, satisfy all of the NEPA planning requirements for implementing an infrastructure project.

As required by NEPA, a major infrastructure project such as I-290 is required at a project level of detail, to undergo:

- An analysis of a "No Build" alternative to define the transportation need. For the I-290 study, the "No Build" is defined as no major improvements in the Study Area; outside of the Study Area, the fiscally constrained major capital improvements contained in the GO TO 2040 Plan are assumed to be in place.
- An analysis of a range of reasonable Build alternatives. As documented in the ongoing I-290 study, a broad range of multimodal (highway/transit mode combinations) alternatives are being evaluated.

- A detailed assessment of the social, economic, and environmental impacts of a proposed action or project. An environmental impact statement (EIS) is being prepared for the proposed project.
- Consideration of environmental sequencing: avoidance, minimization and mitigation.
- Stakeholder involvement: coordination and consultation on every aspect of the NEPA process, including the identification of project needs, evaluation methodologies, and alternatives development and evaluation.

NEPA requires preparation of an EIS for major federal actions that may significantly affect the quality of the human environment. An EIS is a full disclosure document that details the process through which a transportation project is developed, includes consideration of a range of reasonable alternatives, analyzes the potential impacts resulting from the alternatives, and demonstrates compliance with other applicable environmental laws and executive orders. IDOT and FHWA are preparing an EIS for the I-290 Study.

An EIS requires a greater level of travel forecasting model detail than for a long range transportation plan, because of the need for environmental impact evaluation, as well as engineering design and financial analysis, including toll revenue forecasting. The socio-economic forecasts are the main input to the travel forecasting model, and should therefore reflect current available land use and socio-economic conditions, historic trends for the Study Area, and pending development and redevelopment proposals, particularly those that will exceed regulatory limits on density or other factors.[1] The I-290 socio-economic forecasts, which are market driven, are consistent with these requirements.

The No Build Scenario excludes all major capital projects in the Study Area to determine No Build conditions. The No Build Alternative serves as a benchmark against which the transportation needs are defined and the Build Alternatives are compared. To analyze the No Build Alternative, as well as the Build Alternatives for the proposed project, corresponding 2040 socio-economic forecasts are required.

Section II presents the Market-Driven No Build socio-economic forecasts developed for the proposed project. The ACG Market-Driven forecasts (i.e. No Build) were prepared in 2011 through 2013 in close collaboration with CMAP. Over this period, ACG: The al Chalabi Group, Ltd. conferred with CMAP staff in its development of a Market-Driven socio-economic forecast. Because it was intended for use in multiple projects, forecasts were prepared for the extended (21-County, three-state) Chicago Metropolitan Area. This Market-Driven forecast accepts and incorporates the 2040 total population (and corresponding household and employment) forecasts for the CMAP region; but, it differs in the distribution of those forecasts. The collaboration with CMAP staff was intended to establish the ground rules for developing an

[1] Interim Guidance on the Application of Travel and Land Use Forecasting in NEPA, Federal Highway Administration, March 2010.

alternative, but complementary, forecast for the seven-county CMAP portion of the region. These ground rules, as set by CMAP staff[2], are:

- Articulate alternative assumptions.
- Show the math.
- Produce standard outputs (required for CMAP regional travel models).

This report describes those steps, as initially employed by ACG/Parsons Brinckerhoff, Inc., in the No Build scenario for the Project Corridor, whose direct impact area includes portions of the CMAP planning region. As the CMAP transportation demand model covers 21 counties in Illinois, Indiana and Wisconsin; and as these forecasts were intended for use in multiple projects, the ACG Market-Driven forecasts were generated for the entire 21-Counties CMAP modeling area. The CMAP population forecast was accepted as a control total.

The Market-Driven socio-economic forecasts, by subzone, for the I-290 No Build Alternative scenario, as well as various build alternatives scenarios, were generated by ACG: The al Chalabi Group, Ltd., in accordance with the provisions of a subcontract with Parsons Brinckerhoff, Inc., dated July 20, 2011. The ACG subzone forecasts were based on ACG-generated Market-Driven (trends) township forecasts. The distribution of the township forecasts to subzones considered, among other factors, the distribution of the NIPC/CMAP 2030 forecasts developed under the agency's quasi Market-Driven (trends) methodology; forecasts developed for Kankakee County; forecasts prepared for Northwest Indiana counties, and forecasts prepared for the Rockford metropolitan area.

The Market-Driven forecasts were also based on 2010 Census data, 90 years of historic population and employment data for the region, current and previous regional socioeconomic forecasts, land availability for development, population holding capacity, demographic data and trends (household size, migration patterns, etc.), local land use policies, and independent Woods & Poole economic forecasts. The I-290 market-based forecasts take into account the recognizable and well-documented pattern of growth of an urban area outward from a central core, incorporating existing older towns and creating new centers at nodes of high accessibility.

As prescribed by NEPA, the I-290 market-driven No Build socio-economic forecast takes into account the transportation improvements that are committed (included in the region's Transportation Improvement Program). The No Build socio-economic forecasts also excludes all major capital projects within the Study Area (no I-290 capacity improvements or CTA Blue Line Extension), while taking into account the fiscally constrained major capital projects outside of the Study Area.

The I-290 No Build socio-economic forecasts were used in development of the project's Purpose and Need. This forecast, which is "alternatives neutral" was also used for the evaluation and

[2] "CMAP Forecast Principles for data users and forecast developers", Chicago Metropolitan Agency for Planning, April 2011.

screening of preliminary alternatives in Round 1 Single Mode Alternatives Evaluation and Round 2 Combination Mode Alternatives Evaluation described in Sections 2.3 and 2.4 of the DEIS. Rounds 1 and 2 included 30 alternatives, which made individual forecasting for each alternative impractical.

Section 3.0 describes the differences between the CMAP Policy-Based forecasting approach and the I-290 Market-Driven approach, and why the Market-Driven approach was selected for use in the I-290 Study. CMAP's approach for the GO TO 2040 Plan was to integrate land use and transportation policy that resulted in a "policy-based plan (dealing with the investments and high-level choices that shape our region) as opposed to a land use plan (dealing with specific types of development in specific locations)."[3] Policy-based forecasts are designed to re-direct growth to achieve the desired outcome. The scenario-driven, policy-based socio-economic forecasts reflect the plan's desired outcome (i.e. the Preferred Scenario) and assume that the recommended policies will be in place by 2040 in order to achieve these. The Preferred Scenario promotes infill and reinvestment as the primary policy drivers and integrates the socioeconomic and land use assumptions with a fiscally constrained set of transportation improvements intended to support regional planning goals.

As background, the method used by CMAP to develop the 2040 population and employment forecasts was a radical departure from previous forecasting practices in the region. Prior to the GO TO 2040 Plan, the socio-economic forecasting practice in northeastern Illinois was based on municipal and county consultation, historic trends, local land use policies, local development proposals, available land for development, and regional and county level control totals, in a "market-based" approach. This prior socio-economic and land use methodology and forecast was adopted as the planning baseline for the region and used for major project development and for the long range transportation plan.

Due to the following considerations, the CMAP GO TO 2040 Plan socio-economic forecasts were not used for the NEPA process for the I-290 Study:

- While CMAP's socio-economic forecasts represent its "preferred regional scenario" for development, the agency recognizes that the implementation of its vision relies on a multitude of decisions made at different levels of local, state and federal government. CMAP does not have authority to implement local land use plans. The authority over local land use resides with local government. Local zoning ordinances often do not allow the type of high density redevelopment proposed in the CMAP GO TO 2040 Plan, so that the redevelopment in these fully-developed areas is not likely, given current local policies and prevailing market conditions.
- At the time the proposed project was initiating its socio-economic forecast development, 2010 Census results had just been released. However, CMAP chose not to update its GO TO 2040 socio-economic forecasts when the 2010 Census results became available, instead

[3] CMAP GO TO 2040 Comprehensive Regional Plan, October 2010, page 26.

basing its forecasts on 2009 estimates of the 2010 results.[4] Significantly, the actual 2010 Census showed a substantially lower population (nearly 200,000 persons) in the City of Chicago than the 2009 estimate used by CMAP. CMAP updated their socio-economic forecasts in 2014 to reflect the 2010 Census results as part of the GO TO 2040 Plan Update.

- The CMAP 2040 policy-based socio-economic forecasts were completed prior to identifying the fiscally constrained major capital transportation projects. Following the adoption of its GO TO 2040 Plan, which contained its recommended fiscally constrained major capital transportation projects, including the proposed project, CMAP opted not to revise its socio-economic forecasts. The implied assumption was that the policy-based forecasts, which reflected the desired development, would be the same regardless of which major transportation projects were included in the plan. Although the CMAP 2040 Preferred Scenario represents a Build scenario, it is not necessarily reflective of the effects of all individual major capital transportation projects.
- CMAP also prepared a "Reference Scenario" as a baseline during the early stages of the development of the GO TO 2040 Plan. Because the policy direction of GO TO 2040 had not yet been established, the Reference Scenario assumed continuation of current socio-economic and land use trends and no additional transportation improvements by 2040. The Reference Scenario, which is essentially a "no plan" scenario, does not reflect a No Build scenario, as it does not assume any major capital projects outside of the Study Area for the entire planning period.
- Recognizing that all of the intended policy-based results may not materialize, CMAP anticipated and supported the need for major project alternative socioeconomic forecasts as outlined in CMAP's Forecasting Principles.[5] CMAP staff concurred with the methodology utilized for developing the I-290 forecasts.[6]

In summary, IDOT concluded that a strict policy-based forecast, such as CMAP's 2040 socio-economic forecast, was not appropriate for evaluating specific transportation facilities, because it is aspirational in nature, does not directly address population and employment differences between No Build and Build scenarios, and relies on assumptions of redevelopment in mature areas. IDOT determined that a refined market-based forecast, similar to the type of forecasts historically prepared by CMAP, was required in order to provide the most appropriate traffic forecasts for use in the design, environmental analysis, and potential toll revenue forecasting for transportation improvements for the Study Area. In addition, with the potential for tolling options for the project, any potential toll and revenue evaluations needed to finance a project will require investment-grade forecasts. Lenders and bonding agencies are typically reluctant to assume that goal-based, policy-driven recommendations will be entirely effective in the face of

[4] CMAP itself explains that "[t]he 2010 estimates used as the base for the 2040 forecast were internally-derived and not based on 2010 Census data, which were not available during the GO TO 2040 process." https://www.cmap.illinois.gov/data/demographics/population-forecast.

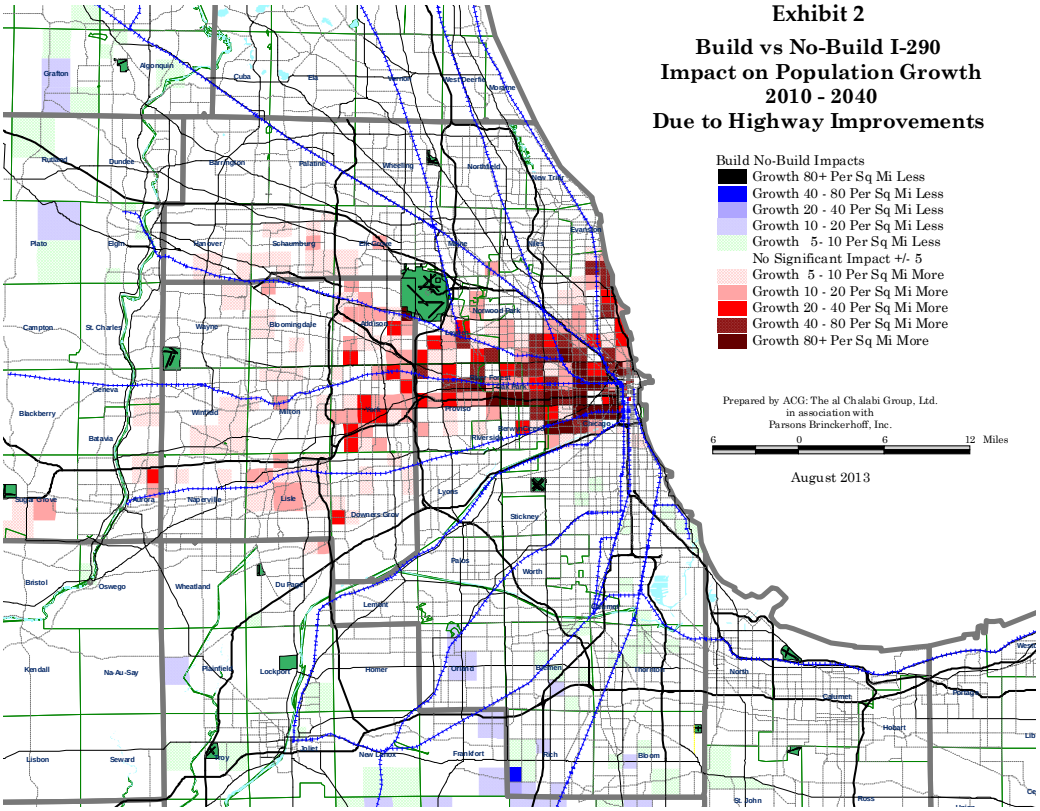
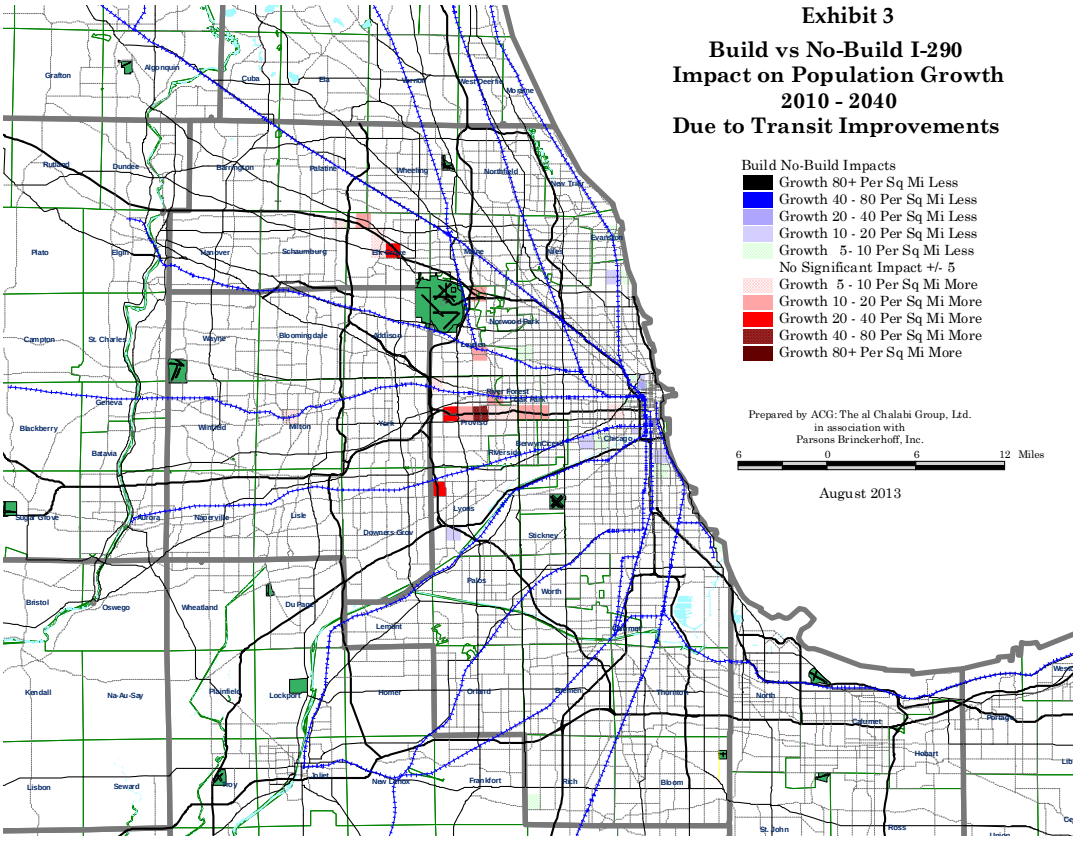
laissez-faire market economics. The Illinois Tollway has developed a similar market-based socio-economic forecast approach for use in their toll revenue studies.

Section IV describes the development of the I-290 Build Scenario, which was used in the Round 3 DEIS Alternatives evaluation (described in Section 2.5 of the DEIS). The Build Alternatives for the I-290 DEIS are combinations of highway and transit improvements, including managed lanes, the CTA Blue Line Extension (or similar high capacity transit facility), and other transit, roadway, and non-motorized improvements.



The introduction of Build Alternative transportation improvements in the Study Area results in changes in regional accessibility, which directly effects population, household and employment forecasts. The improvement of access to developable or redevelopable sites increases the development potential of those sites, attracting development (residential, commercial/ industrial, institutional) that may have occurred elsewhere in the region. Exhibit 1 graphically depicts the improved highway travel times resulting in the Build Alternative versus the No Build Alternative. As seen in this graphic, there are highway travel time improvements in the City of Chicago, suburban Cook County, and DuPage County resulting from the Build Alternative.



Because the I-290 Build scenario includes both highway and transit improvements, it was determined that composite accessibility effects should be used to measure changes in

accessibility for the Build scenario. The percent change in accessibility was applied to changes in household and employment forecasts (2010-2040) to generate the impact of the Build transportation improvement. It should be noted that the sum total of positive impacts (more growth) is set to equal the sum total of negative impacts (lesser growth). The implication of this assumption is that total overall regional growth (within the transportation modeling region) is unchanged – i.e. transportation improvements result in the redistribution of socio-economic activities rather than generating additional regional growth. This assumption has been imposed, by IDOT and Federal agencies, on Build/No Build analyses to discourage the generation of exaggerated benefits for any given project. It is true that some major transportation projects do result in an increase in the accessibility of the region, as a whole; such projects may imply additional growth for the region. However, the Build/No Build analysis guidelines do not allow for changing the regional growth totals. The Build/No Build analysis is intended to measure only the redistribution impacts of the project.

Exhibits 2 and 3 show the impact of the Highway Component of the I-290 Build Alternative on the redistribution of 2010-2040 population and employment growth, whiles Exhibits 4 and 5 show the impact of the Transit Component of the I-290 Build Alternatives. These figures show that the Highway Component of the I-290 Build Scenario has a greater impact on population and employment growth than the Transit Component of the Build Scenario due to the greater improvement in accessibility from the highway improvements.

Due to Transit Improvements

A comparison of the resulting Study Area 2040 population and employment forecasts is shown in Table 1. As seen in this table, the Study Area population and employment forecasts for the No Build versus Build Scenario show less than one percent change. This is due to the existing built-out urban conditions in the Study Area and that the I-290 Study reflects improvements to an existing facility that already provides accessibility to the Study Area.

Table 1. Comparison of 2040 I-290 Study No Build and Build Forecasts

Forecast	2040 No Build	2040 Build	Change
Population	649,215	651,912	0.4%
Employment	309,334	310,967	0.5%

Given the less than one percent difference in population and employment between the No Build and Build Scenarios, it was determined that a single Build Scenario could be used for the four DEIS Build Alternatives. The four DEIS Build Alternatives have nearly identical physical transportation improvements, with the primary difference among alternatives being operational – how the fourth lane in each direction is managed and if there is tolling. The HOV 2+ Alternative was used to develop the highway and transit travel times for use in determining the composite accessibility for the 2040 Build Scenario, because it represents a middle ground or operation control in terms of lane management.

Section 5.0 reflects the updated CMAP 2040 socio-economic forecasts developed for the GO TO 2040 Plan Update (2014). The updated CMAP forecasts are closer, but still higher, than the I-290 forecasts for the City of Chicago (+1.8%), Suburban Cook County (+4.8%), and DuPage County (+8), which are the main travel markets for the I-290 Corridor.

A comparison of the Study Area 2040 population and employment forecasts was performed, as shown in Table 2. As seen in this table, the Study Area population forecasts for CMAP and the I-290 EIS are within one percent of each other.

Table 2. Comparison of 2040 Study Area Socio-Economic Forecasts

Forecast	2040 Population	2040 Employment
CMAP Updated Forecast	645,950	256,590*
I-290 No Build Forecast	649,215	309,334**
I-290 Build Forecast	651,912	310,967**

* IDES employment definition ** BEA employment definition

2.0 Market-Driven Socio-Economic Forecasts - "No-Build" Scenario

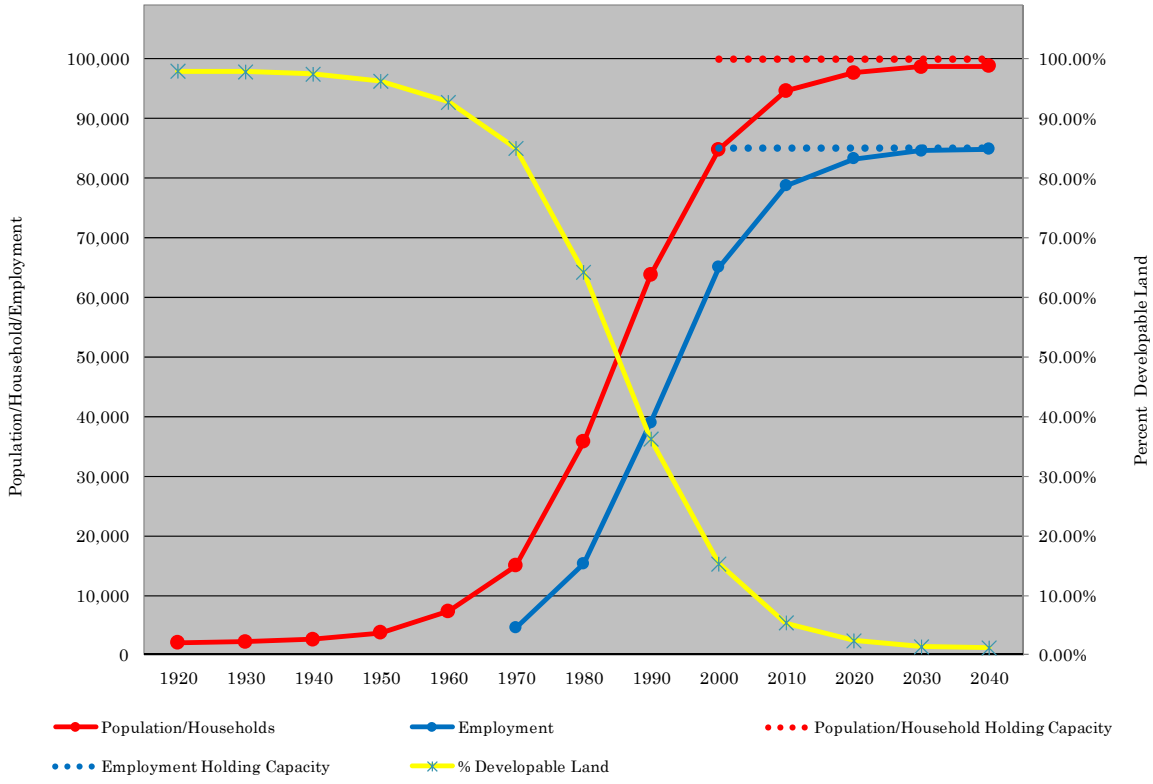
A. Transportation Network Assumptions

The 2040 Market-Driven No Build baseline socio-economic forecasts reflect 2040 conditions assuming no I-290 Eisenhower Expressway improvements (no additional lanes on I-290) and no high capacity transit extension to the west of the CTA Blue Line Forest Park Branch (no Blue Line extension) within the Study Area. The 2040 No Build baseline socio-economic forecasts do assume the implementation of fiscally constrained major capital transportation projects included in the metropolitan transportation plan for the region outside of the Study Area, and the Transportation Improvement Program for the region.

Since the adoption of the metropolitan transportation plan in 2010 by the MPO Policy Committee, the Jane Byrne Interchange (formerly the Circle Interchange) and the Illiana Corridor were amended into the metropolitan transportation plan in 2013. The metropolitan transportation plan was updated and adopted by the MPO Policy Committee in 2014 and included these two major capital projects. The I-290 socio-economic forecasts were based on the metropolitan transportation plan (2010) and did not account for the two projects. The Jane Byrne Interchange project is improving the existing interchange by adding capacity to existing ramp connections, with no substantive access changes. Given the small change in population and employment for the Study Area in the 2040 Build condition versus the No Build for the proposed project, which also maintains existing access, but provides a substantial increase in mainline capacity, the ramp capacity improvements at the Jane Byrne Interchange would have a negligible effect on population and employment since the project is of a smaller scale with regards to increased capacity. The Illiana Corridor is approximately 40 miles south of the I-290 Corridor and serves an entirely different travel market, including long distance inter-state truck trips. The regional population and employment changes may be greater for the Illiana Corridor, as it is a proposed new toll road, but the effects on accessibility will typically diminish as you move away from the facility. With the I-290 Corridor 40 miles away from the Illiana Corridor, changes in population and employment with respect to the proposed project would be relatively minor.

B. Population, Households and Employment Forecasts - General Approach

Population, households, and employment are the three most-important variables used in the socio-economic forecasts for transportation planning. To understand the growth dynamics of these three variables, it was necessary to review the development history of the region and to identify the factors that caused its spatial growth and development. National and regional economic factors: transportation networks (rail, port, expressway and airport), infrastructure



development, and land availability were identified, early, as being critical. Forecasts by CMAP, supplemented by Woods & Poole Economics, were accepted as regional control totals. Local land use plans and regional land use policies were analyzed to establish the township holding capacities for population, households, and jobs. The township was the major planning unit; its totals aggregated to the County; and its details examined at the quarter-square mile level.

From these preliminary analyses, a Standard S-Curve (or logistics curve) was used to describe historic growth, take-off development, and maturity at the township level; an S-Curve describing land availability and holding capacities describes its inverse. The theoretical basis of the Market-Driven forecasts is as follows:

- Township population, household and employment growth progress through several phases:
  - Initial farming base
  - Take-off phase
  - Growth period
  - Maturity/stability
  - Opportunities for redevelopment
- Development follows a logistics function shaped by:
  - Location
  - Time/technology
  - Density/plan/zoning
  - Available land

A representation of this function – a Standard Logistics S-Curve – is shown in Exhibit 6, below. It should be noted, that the use of the S-Curve to explain population and/or household growth and forecasts, within physically-defined boundaries, dates back to the mid-nineteenth century. This formulation has gained popular acceptance, recently, among planners. However, before accepting and applying it to generate Market-Driven forecasts, it had to be tested against long-term trends, at the township level, in Northeastern Illinois – for which historic demographic, economic and land use data are available.

Exhibit 6
The Standard Logistics S-Curve

C. Population and Employment Forecasts – Defining the Methodology

The process of metropolitan area development and suburbanization are fairly well-known and understood. The growth of an urban area – outward from a central core, incorporating existing older towns, and creating new centers at nodes of high accessibility – follows a generally-recognizable and well-documented pattern.

This process and its general pattern are tempered by four major factors:

- Technology at the time growth is occurring – in terms of transportation, manufacturing and construction.
- The underlying economy of the nation and region, plus impacts of a global economy.
- Societal preferences for, and ability to afford, densities and amenities in both residential and commercial developments.
- The siting and construction of major growth magnets – airports, universities, research facilities, corporate headquarters/campuses, regional commercial/office/medical centers, logistics centers.

There are additional demographic trends which are major factors in prompting density changes. These include:

- Family or household size
- Household income levels
- Jobs per household
- Ethnic characteristics and immigrant levels

The process and the first three factors, above, are addressed directly in this study. The fourth is addressed, indirectly, at the township level, and through past immigrant (international and domestic) trends at the county/sub-county levels. All four factors affect density levels utilizing or passing through existing structures, as well as creating demand for new.

Whatever the rate of change or density of development, growth within a county, a township, or a smaller unit ultimately reaches a point at which it can no longer continue unimpeded. The ACG research estimates that this is the point at which: available, vacant land, at the county level, has fallen to approximately three-to-five percent; and land, at the individual township level, has declined to one-to-three percent.

D. Historical Growth of the Region and its Influence on Long-Range Development

As previously stated, a region's growth follows generally-recognizable patterns. Documenting the Greater Chicago Region's historic growth, therefore, was a crucial element in this analysis. Exhibits 7 through 15 show the population change, by township, for each decade, starting in 1920 and ending in 2010. The outward growth of the region; the influence of transportation facilities; and the phases of growth relative to regional job centers and economic conditions can be clearly identified.

It should be noted, that Exhibit 15 reflects the final results of the 2010 Census. Prior to this report, the U.S. Bureau of the Census had been releasing annual population estimates, by township, since the prior decennial Census. The actual 2010 Census population differed from the 2009 estimate, including:

- Substantial decrease in the City of Chicago, where growth was anticipated and expected during the last few years of the decade;
- Higher growth in the region's fringe; and
- Lower growth in the maturing townships, except for those receiving immigrant groups.

E. Market-Driven Socio-Economic Forecasts by Township – Calibration and Forecasts

The maps in the preceding section, documenting the population change by township per decade, represent one method for visualizing the outward growth of the region, the cessation of growth once land is fully developed, and the impact of local and national economic trends (cycles) on development.

A second method is to present the population, households, and/or employment trends, forecasts and S-Curve graphs for a cross-section set of townships extending from the edges of the City of Chicago outward. Seven sample townships along the Region's east-west central highway axis (Eisenhower Expressway (I-290) and Ronald Reagan Memorial Tollway) represent a typical cross-section and time-line of the Region's growth. These townships are Proviso, in Cook County; York, Lisle and Naperville, in DuPage County; and Aurora, Sugar Grove and Kaneville, in Kane County. Exhibit 16 shows the locations of these townships within the Chicago Region. Each of these townships represents a different development take-off and maturity year, generally (one exception) at a later date proceeding from east to west. Slightly different graphs, showing similar data for Community Area Groupings within the City of Chicago, along the Project Corridor, also are presented in the next section of this section.

Exhibits 17 through 23 (shown within their township descriptions) show the population, households and available land trends (through 2010) and the Market-Driven forecasts (post-2010) for the above-referenced townships. Also shown on these graphs, are the population and household (same as occupied housing units) holding capacities. Two sets of trends and three sets of forecasts are shown. The solid lines (red for population and blue for households) represent the mathematically-generated S-Curve hypothetical trends and forecasts. The dashed (also red and blue) lines represent actual past trends (through 2010) and the 2010-2040 Market-Driven forecasts generated for the I-290 Study. The large solid dots (brown for population and dark blue for households) represent the CMAP data (2010) and its two forecasts for 2030 and 2040. The S-Curve equation and its input data are:

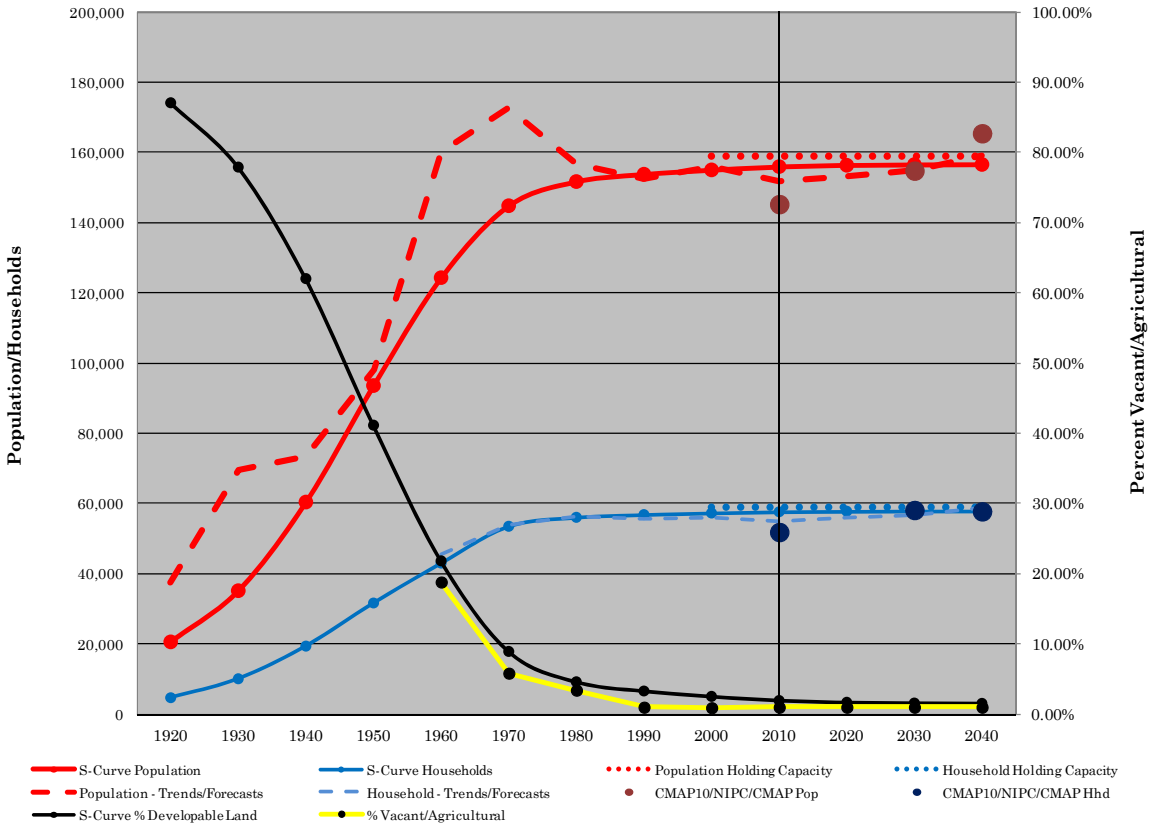
Forecasted Household/Population/Employment =
Holding Capacity/(1+EXP(–alpha*(Year–Year0))).
Where:
alpha = (LN(1/Value1–1) – (LN(1/Value 2–1))/(T2–T1)
Year0 = (LN(1/Value1–1)/alpha+T1)
and
T1 = take-off year (at which point acceleration is pronounced) (e.g. 1948)
T2 = approaching maturity year (e.g. 2005)
Value 1 = % of peak household/population/employment at take-off year

Value 2 = % of peak household/population/employment at approaching maturity

The black lines, in these graphs, represent the S-Curve hypothetical land available for development, measured as percent of total township land, as shown on the right axis. The yellow lines represent the actual, through 2010, and the I-290 EIS (Market-Driven) forecasts beyond 2010; both are measured as percent of total land. The source of land available for development are from the Chicago Regional Plan Association (1956), and NIPC/CMAP land use survey (through 2005 with ACG extrapolation to 2010). The 2010 CMAP land use inventory was not completed until after the I-290 EIS forecasts were finalized, so was not included in this socio-economic forecast analysis.

Exhibit 17 shows the trends and forecasts for Proviso Township. Proviso Township is the first, nearly full-sized township (full-sized is 36 square miles) west of Chicago. The take-off year for residential development and population growth occurred in approximately 1920. Employment take-off occurred later that decade. By 1970, less than 10 percent of total land was available for development, an indication of approaching maturity. By 1980, only three percent of total land was available for development; this is an indication of full development beyond which redevelopment becomes the norm. It should be noted that, at the township level and applying Market-Driven assumptions, redevelopment seldom results in increased population or household densities. The household S-Curve replicates the historic trends very well; whereas, the population S-Curve underestimates the population during the period of the mid-1950's through the 1970's. This was a period of high birth rates (birth of the baby boomers) resulting in the large average household size. The better performance of the S-Curve equations in predicting household trends is the reason for shifting from using S-Curves to predict population to one of predicting households and deriving population from households.

Exhibit 17: Proviso Township - West Suburban Cook County



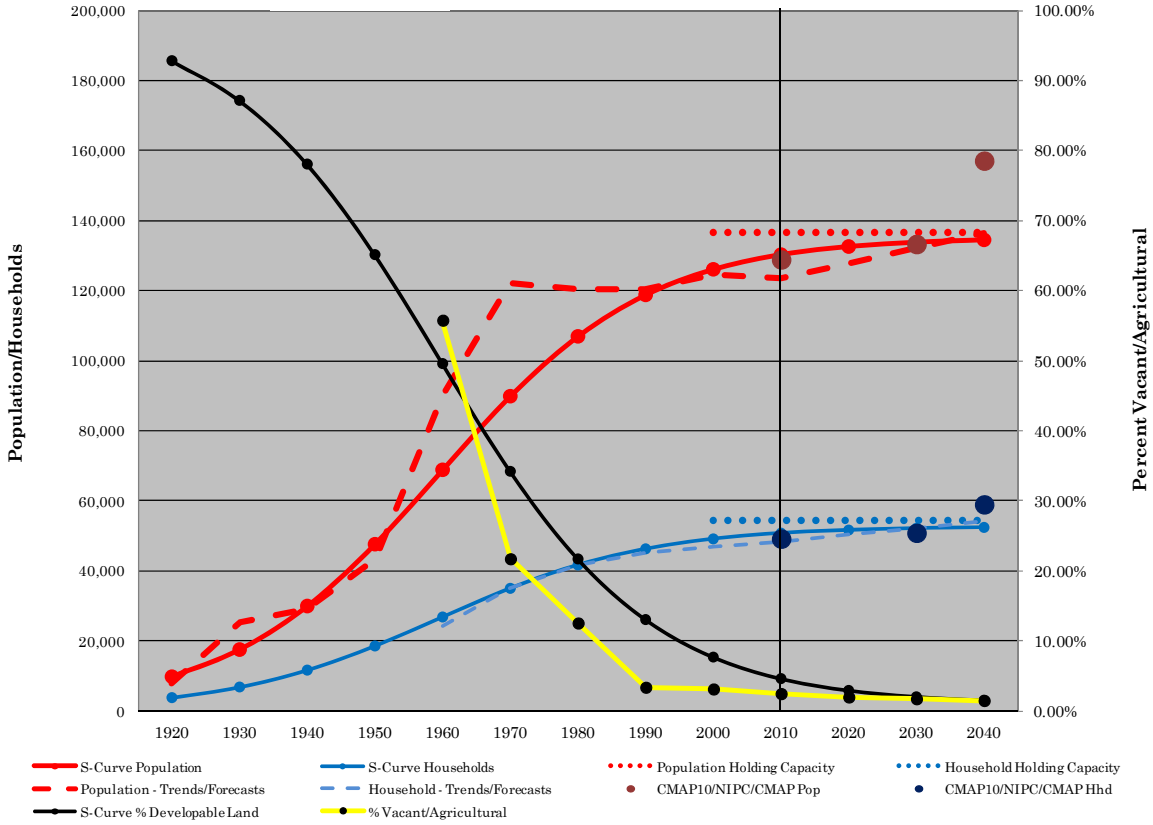


Exhibit 18 shows the population and household trends for York Township, DuPage County[7]. The intersection of the Tri-State Tollway (I-294) and the Ronald Reagan Memorial Tollway (I-88) occur on the eastern edges of this township. This intersection, which was part of the initial Illinois Tollway system put into service in 1959, caused York Township to become one of the most-important regional centers within the Chicago MSA. The northern section of I-355 (Veteran Memorial Tollway), opened in 1989, is located along the western edges of the township, further enhancing its accessibility. York Township started its population and residential development take-off in the mid-1930's and approached its residential maturity by the mid-to-late-1980's. York Township's historic household and population trends and their relationship to the S-Curve equations are similar to those observed for Proviso Township. The household predictions are uniformly accurate; whereas, the population S-Curve underestimates the population during the high birth rates and consequent large household size experienced in the 1950's and 1960's.

Exhibit 18: York Township - DuPage County

The York Township take-off for employment (Exhibit 18A) occurred in the 1960's, shortly after completion of the initial Illinois Tollway system. The township employment began approaching

[7] For the sake of clarity and readability, employment trends were shown on separate graphs; an example (York Township) is shown as Exhibit 13A.

its employment maturity by 2000. The recent Great Recession caused many of York Township's employers to reduce their number of employees. Most of the employment in York Township is office or retail-based and is assumed to return to pre-recession level and expand to occupy available holding capacity by 2040. It is worth noting that York Township, due to its excellent accessibility to the rest of the Chicago MSA, has more jobs and a larger employment holding capacity than population and household holding capacities. York Township's population and household growth patterns anticipated those of its employment growth. Once again, the population/household patterns reflect the baby boom experience of the 1950's and 1960's.

Exhibit 18A: York Township - DuPage County

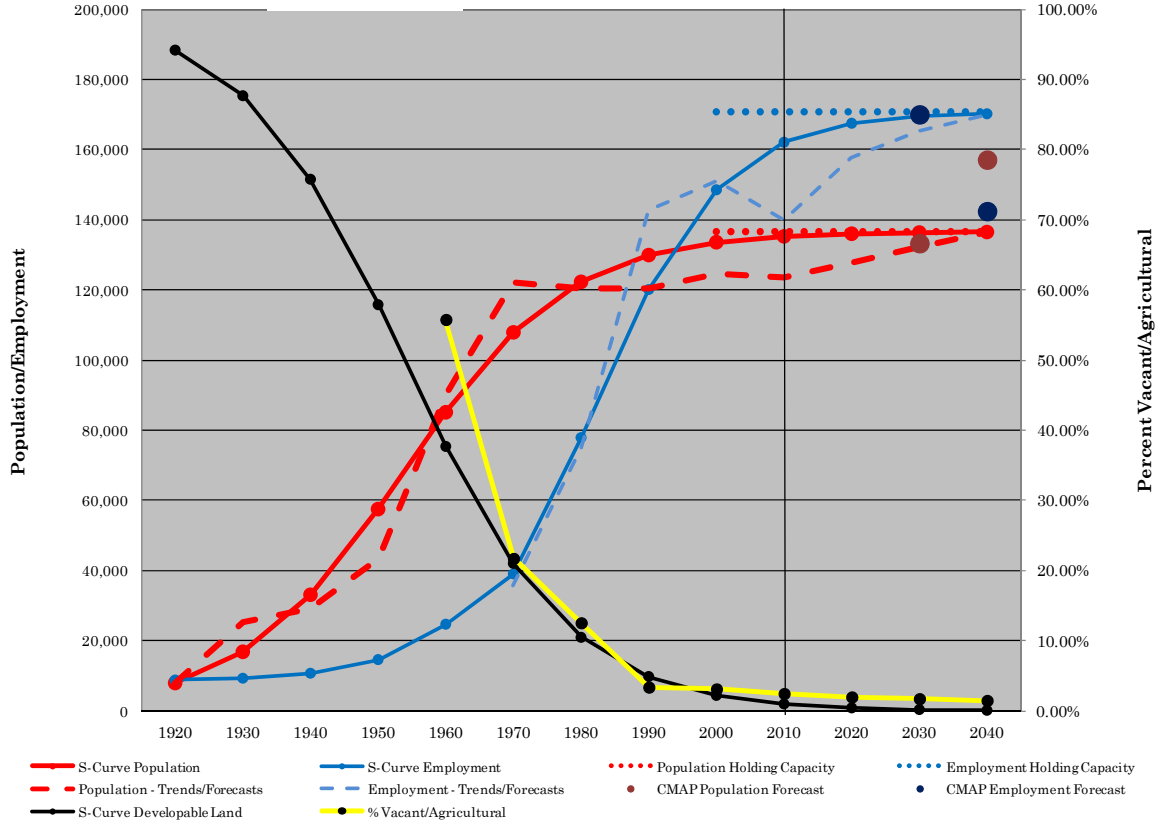

Exhibit 19 shows the population and household trends and forecasts for Lisle Township, DuPage County. The residential take-off for this township occurred in the early 1960's and approached maturity by the mid-2000's. Again, the household S-Curve is a better predictor than the population S-Curve. The difference is not as stark as those observed in York and Proviso Townships because most of the growth of this township occurred shortly after the birth of the Baby Boomers.

Exhibit 19: Lisle Township - DuPage County

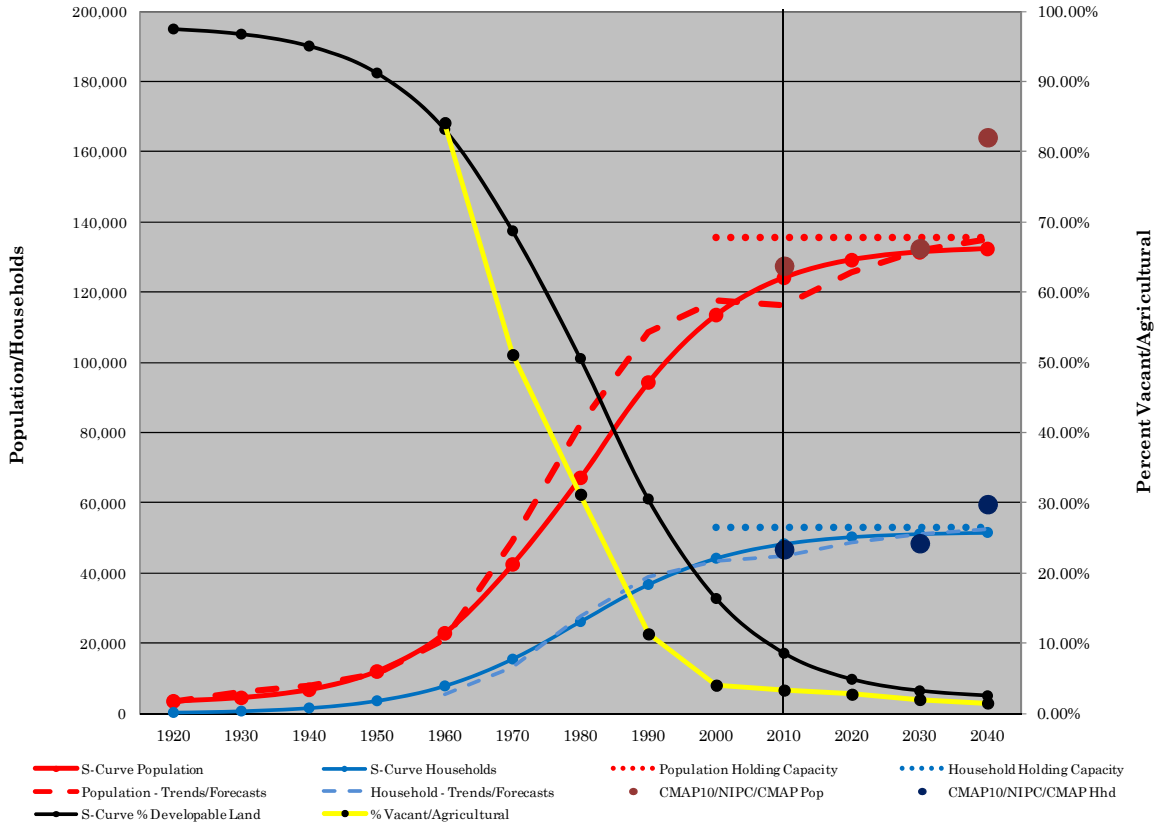

Exhibit 20 shows the trends and forecasts for Naperville Township. The residential and population take-off occurred during the early-1980's – almost two decades after Lisle. Maturity is forecasted to be approached by the mid-2010's. Both the household and population S-Curves are good predictors of past growth as most of this township growth had occurred after the large average household size associated with the Baby Boomers.

Exhibit 20: Naperville Township - DuPage County

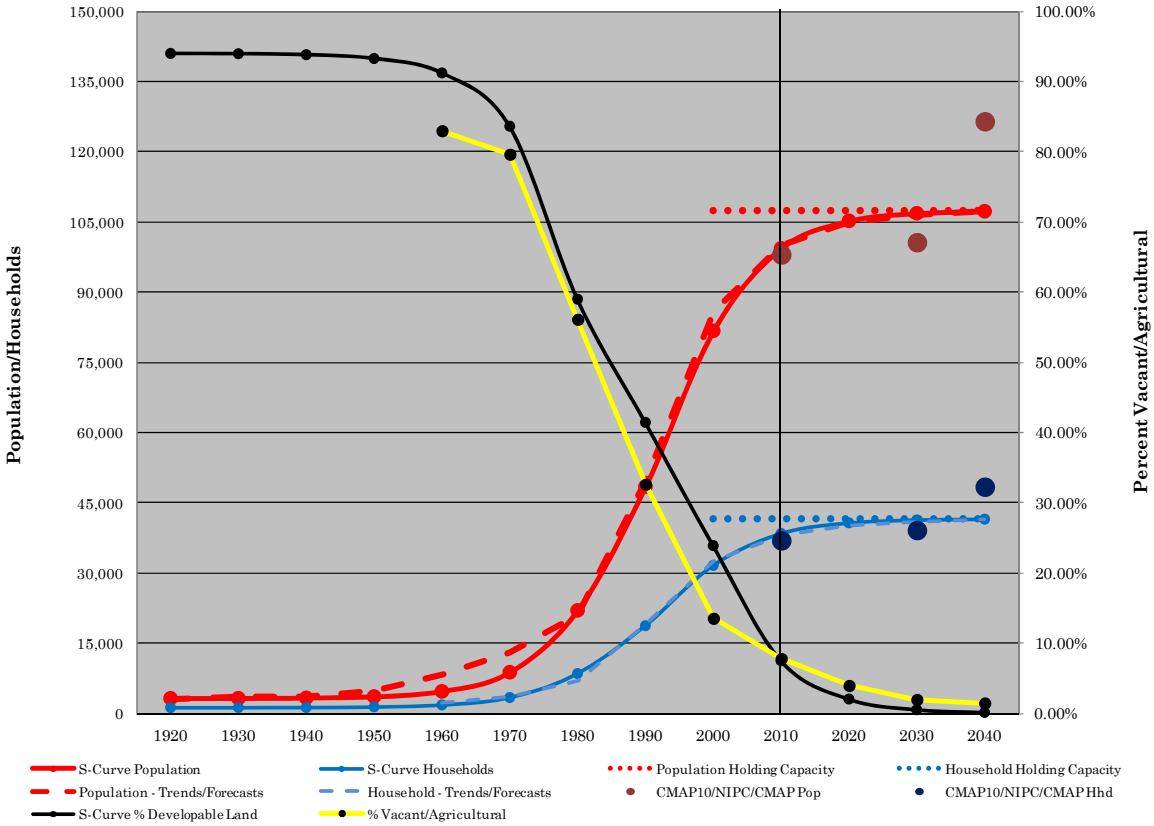

Exhibit 21 presents the growth trends and forecasts for Aurora Township. This township is one of four unique townships within the CMAP Region. Each of these four townships include one of four satellite cities (Aurora, Elgin, Joliet, and Waukegan). Each of these satellite cities was a pre-railroad city, established in the first half of the 19th Century and located approximately 45 miles from Chicago, which was established at approximately the same time. These satellite towns grew and developed as industrial centers, independent of Chicago. Each of these towns reached a mature, stable population and employment by the 1960's, at which time they remained separated from Chicago by large tracts of agricultural land and operating farms. In the 1990's, the suburban edges of a developing Chicago reached them. Since they still contained agricultural and vacant land, development was relatively reasonable; and these townships started growing again. Aurora Township's growth is shown as a double S-Curve. The mathematical equation is slightly more complex; but the hypothetical curves are presented for population and household growth. However, the hypothetical prediction of the percent of land available for development, which is the inverse of the sum of the population and employment S-Curves, is not shown as a double curve.

Exhibit 21: Aurora Township - Kane County

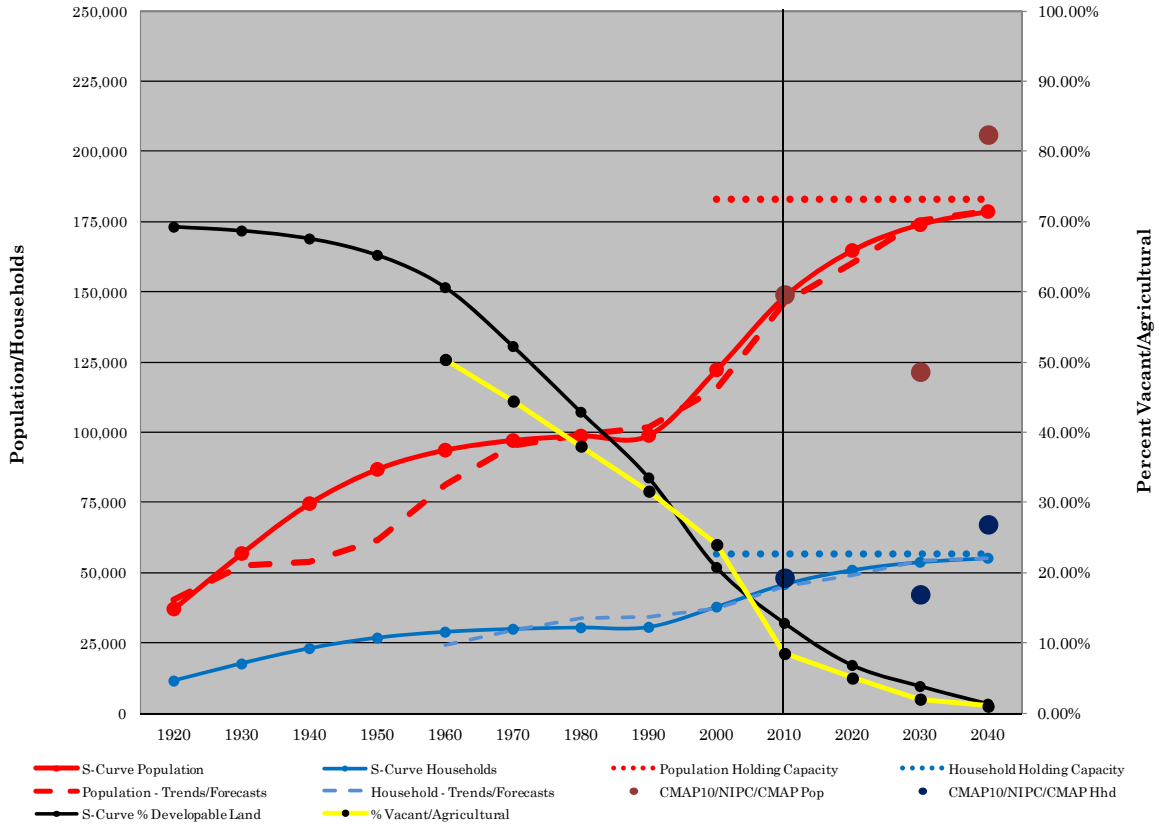

Exhibit 22 shows the growth trends and forecasts for Sugar Grove Township. Development take-off started in the mid-2000's and is forecasted to approach maturity by 2050. As the townships in DuPage reach full development, and developable land is no longer available there, urban growth will push outward. Sugar Grove Township is one of those outward townships that, currently, is starting to experience growth. Growth during the coming decade will be slower than predicted by the hypothetical S-curve because its early years will reflect the impact of the recent recession, and its slower-than-historical return to normalcy.

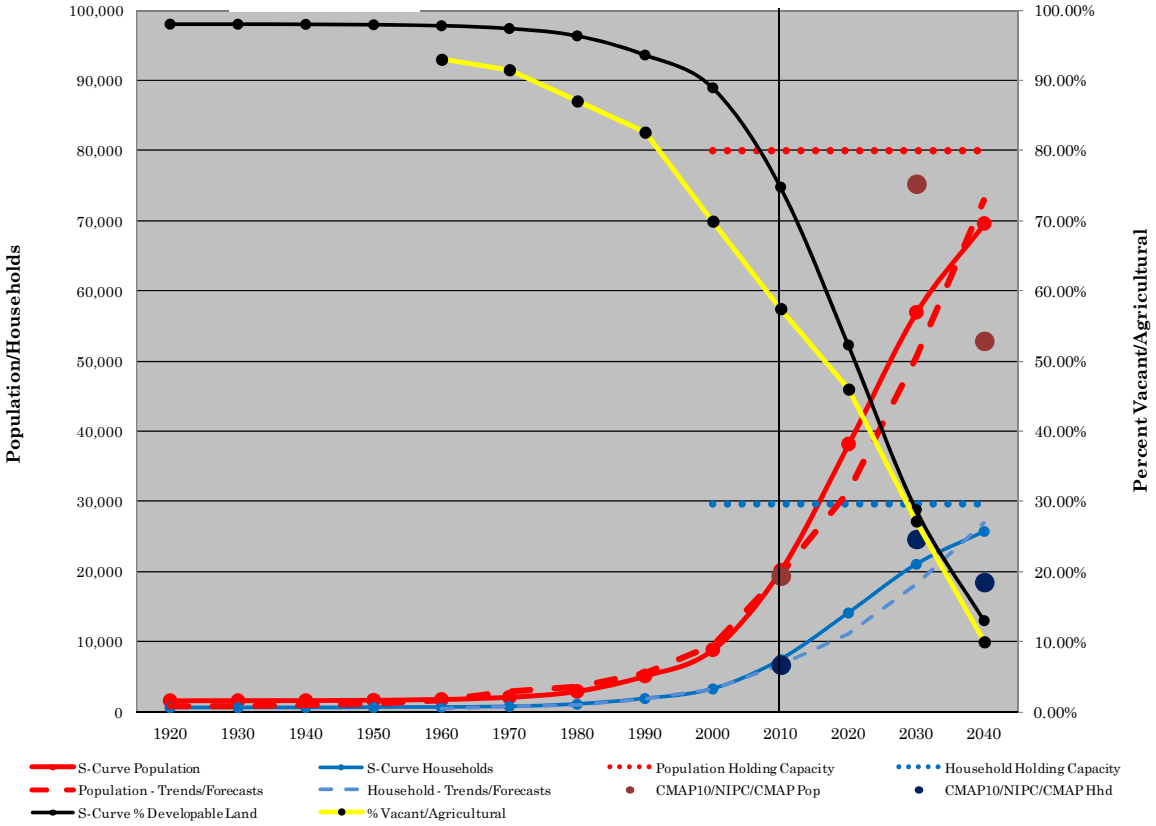
Exhibit 23 shows Kaneville Township; this township is the west-most township along the I-88 corridor within the CMAP Region. Development take-off is forecasted to start by the mid-2030's and tentatively is assumed to reach maturity by 2070. The township west of Kaneville is Pierce Township, in DeKalb County; this township is forecast to remain an agricultural township throughout the entire forecast period, 2010-2040. The population of Pierce Township declined from 638 in 1920 to 454 in 2010 and is forecasted to remain at approximately 450 through 2040.

Exhibit 22: Sugar Grove Township - Kane County



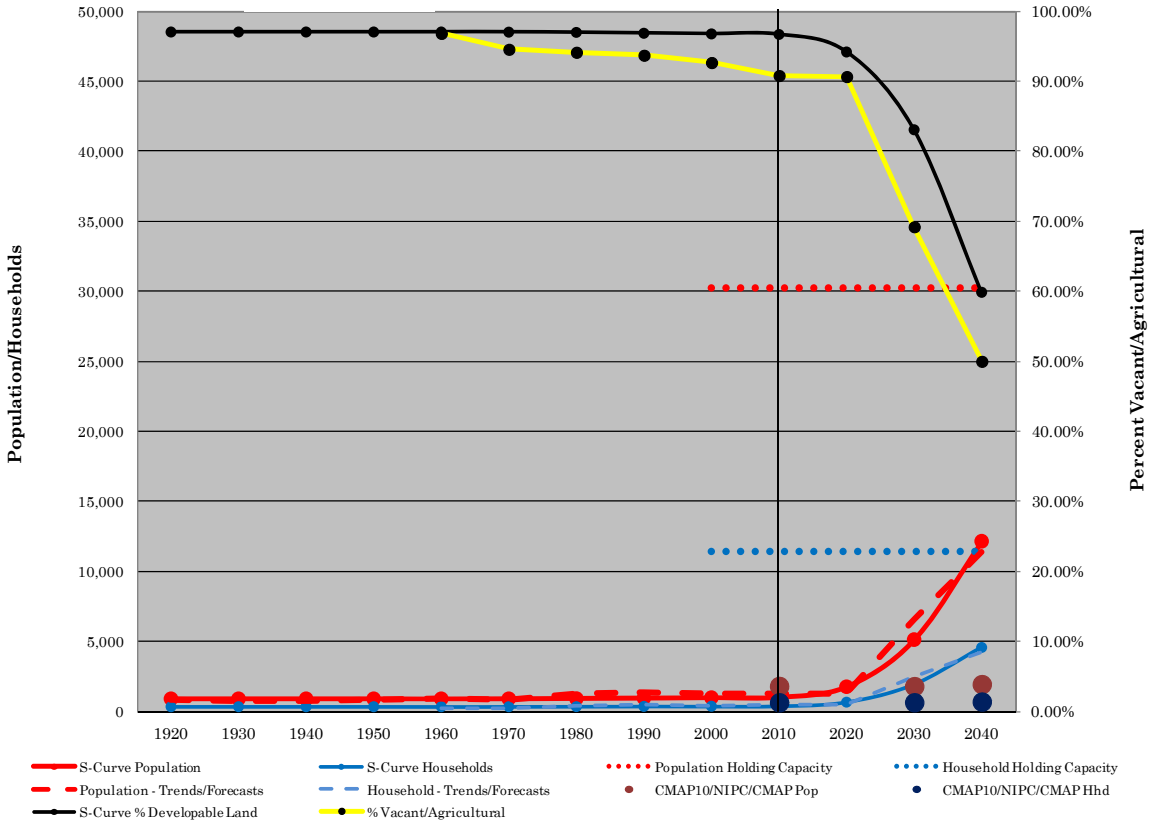


Exhibit 23: Kaneville Township - Kane County

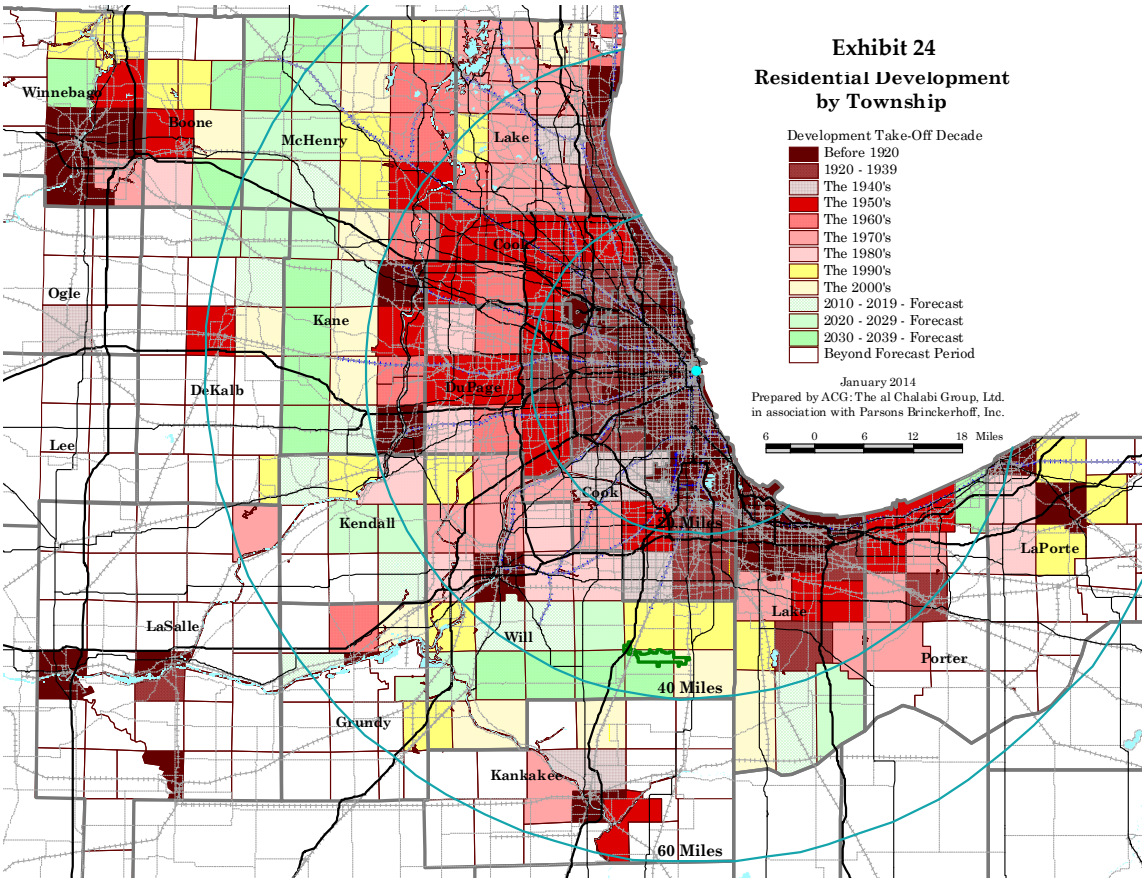


Graphs similar to those presented here, have been prepared for each of the 118 townships (several of the 124 political townships were combined to better approximate the 36-square mile surveyor townships) in the CMAP Region and the 168 townships, in Illinois and Indiana, that are within the CMAP transportation modeling area, but outside CMAP. The 168 external townships lack land use data. However, most of these are agricultural townships and are forecasted to remain so throughout the forecast period. For the few external townships where land use data are needed to calculate holding capacities, web-available satellite photographs were used to approximate land use data. For all townships, the population and employment forecasts, as generated by ACG, are influenced by available local, county and regional plans and forecasts; tempered by the S-Curve graphs; and constrained by the regional population forecasts initially generated by CMAP and accepted for the I-290 EIS.

Exhibit 24 shows the Take-Off Year of Residential Development for each Township, as implied by the S-Curve equation data for the previously-illustrated townships and each of the 300-plus townships in the Greater Chicago Region. It illustrates and verifies the historic expansion and maturation of the region; whose development was located:

- First, along the Lake Michigan shore; in the region's satellite cities (Waukegan, Elgin, Aurora and Joliet), and in further-out, independent cities (Rockford, Ottawa, Kankakee and Michigan City).
- Second, along early interurban commuter rail and historic highways (e.g. U.S. 30 and US 41).
- Third, along major expressways constructed in the 1950s and 1960s and in post-WWII suburban areas.
- Fourth, reflecting the impact of O'Hare International Airport, in pulling development from its historic concentric focus, as it competes with the Central Area of Chicago as the region's dominant economic focus.
- Fifth, the expanding edges of the region.
- Sixth, growth of satellite cities toward the expanding urban edge.

This map clearly shows: the constraints imposed, in the 1930's and 1940's, of Post-Depression economics and World War II (there was no significant growth in the 1930's); the exuberance of post-WWII (1950's) expressway building and low-rate mortgages; the economic impact of Central Chicago, the attraction of the lakefront, and the impact of their access to one another on the region's early development; the economic attraction (in the 1960's, 1970's and 1980's) of O'Hare as national and international businesses grew and required access to clients and as professionals required access to the airport; and the continual search for affordable housing, amenities, and good schools close to job opportunities.

F. Market-Driven Socio-Economic Forecasts by Community Area in the City of Chicago

The City of Chicago is classified as a single township, a township that reached full development by the early 1930's. The population of the City peaked, in 1950, at 3.621 million and, with one exception (in 2000), declined each subsequent decade, reaching a low of 2.695 million in 2010. The occupied household units remained relatively stable; it fluctuated in a narrow band of 1.080 million, in 1950; peaking at 1.155 million, in 1960; declining, thereafter, to a low of 1.025 million, in 1990; and rising to 1.046 million, in 2010. Whereas, between 1950 and 2010, the City of Chicago's population experienced a decline of 25.6 percent, its households decreased by only 3.1 percent over the same period.

The above-cited gross changes in the City of Chicago have camouflaged many serious changes that occurred in the City's communities and sub-areas. Almost all of the changes were the product of redevelopment; as vacant land, available for development, stayed at approximately five percent through the period, 1960-2010. Given these facts, it became evident that it was necessary to subdivide this single township into sub-areas and prepare individual population, household and employment forecasts for each. Furthermore, the use of the S-Curve for replicating past trends and generating future forecasts proved unreasonable, as all sub-areas

within the City of Chicago are fully-matured communities. Accordingly, a more detailed approach, cognizant of the development history and potential of each community, was necessary. This led to the analysis of community areas.

The City of Chicago is composed of 76 Community Areas (77, if the Old Uptown is divided into New Uptown #03 and Edgewater #77). The structure of these Community Areas dates back to the 1930's; and there is a wealth of historic data on the social, geographic, demographic and economic characteristics of each. These 76 Community Areas are aggregated into 12 Community Area Groups (CAG), which are relatively homogenous, by location, physical layout, structures, socio-economics, land use and history. Three of these CAG straddle the I-290 Corridor within the City of Chicago. These three CAG's are (from the Lake westward):

- Central Lakefront composed of Community Areas: 8-Near North Side, 32-The Loop, and 33-Near South Side.
- Near West composed of Community Areas: 24-West Town, 28-Near West Side, and 31-Lower West Side.
- West composed of Community Areas: 23-Humboldt Park, 25-Austin, 26-West Garfield Park, 27-East Garfield Park, 29-North Lawndale, and 30-South Lawndale.

Two approaches were used in forecasting population, households and employment for the City of Chicago. The first, was generated for the City as one township. This 2040 forecast, with a population of 3,000,000, was reported in the 2012 forecasts incorporated into the initial I-290 "No-Build" forecasts. These initial forecasts were further refined through the preparation of forecasts for each of the twelve Community Area Groupings. These refined forecasts are detailed in the report, Comparison of Historic Data and ACG/CMAP Forecasts to 2040 of Population and Housing for the City of Chicago and its Community Areas, prepared for the Illinois Department of Transportation, by ACG: The al Chalabi Group, Ltd, in association with Parsons Brinckerhoff, Inc., in February 2013.

The above forecasts reflect a continuation of the trends of the past few decades, interrupted by the recent Great Recession, which affected both the job and housing markets. Chicago, currently, is resuming these long-term trends, which have resulted in a gradual and unremitting improvement of housing stock and a spreading gentrification of neighborhoods from the Central Area and the Lakefront, outward. Additional trends include:

1. **Combining/Enlarging Housing Units –** This growing phenomenon is flourishing in both single-family neighborhoods and in high-rise condominiums. There has been an on-going trend to combine units in major condominium towers, as homeowners/buyers seek to modernize and enlarge their residences. For example, the Hancock Center and high-rises along the north lakefront show percentage reductions in units (through combination) and residents that closely parallel the city's decline in population over a similar period of time (1990-2010).

   There is a similar trend to replace older, smaller, single-family housing with much larger units, often on several city lots. These units, often referred to as McMansions, line many of the tonier streets of Lincoln Park and Lakeview. Large single-family residences – previously

converted into apartments – have been renovated and returned to single-family use. There also has been major adaptive reuse of industrial and office buildings into lofts and residences, often conferring considerable square footage to individual units.

2. **Abandonment and Demolition –** Over the past twenty years, there has been significant demolition of high-rise public housing, with little replacement. Families often were relocated to nearby suburbs, with the assistance of housing vouchers. In some of the better-served areas, privately-funded market or 80/20 development has occurred – all at a significantly lower density. While vacant land still remains, access is often compromised by elevated rail or highway structures. The result is both reduced housing units and lower density.

3. **Impacts of the Recession on Housing –** Adding to the former abandonment and demolitions, described above, is the very substantial abandonment and foreclosure brought about by the recent Great Recession. Chicago was, and still is, hard hit by this economic challenge, with a foreclosure rate estimated at approximately 3.3 percent of housing units, more than double that of the national average, as of late 2012. At the same time, the foreclosure rate in the State of Illinois was the highest in the U.S.

4. **Available Vacant Land –** In addition to the above-cited vacant land, there are major parcels of land (former U.S. Steel, central railroad land, Chicago River banks, the former Michael Reese Hospital, former Taylor Homes, etc.) which have been or are currently undergoing planning. Most plans show gradual development over the next 20 to 30 years. Development of these parcels has been taken into consideration in this forecast. The result is a slightly larger number of housing units, in 2040, than those forecast by CMAP.

5. **Infill Development –** As a result of older urban renewal programs and the civil disruptions of the 1960's and 1970's, many neighborhoods were confronted with gaps created by demolitions, fires, or abandonments. The treatment of these infill spaces has been very different. In the lakefront communities – Lincoln Park, Lakeview, South Loop, Hyde Park, Near North – and communities radiating outward from the Loop – Near West, Logan Square, Ukrainian Village, etc. – the infill spaces have been filled with new structures. In the still-struggling areas of Lawndale and the South and Far Central communities, they have not. But, infill has simply replaced units that were once there; while at a greater value, they remain at their former or lower densities. It should be noted that infill occurs only when the general area is served or upgraded by a major economic asset, such as a medical center, university campus, regional retail, or access to the Chicago Central Area.

6. **Second-Home Development –** A fairly recent phenomenon is the development of second homes in the City of Chicago – for suburbanites who want a small pied-à-terre in the City to enjoy its lively cultural and entertainment offerings; and for those who enjoy residences in two or more regions across the country or beyond. In some Central Area high rises, second homes now represent five percent or more of the units. Second homes for global citizens have not developed in Chicago at levels comparable to those in London, Paris, New York

and Miami. However, such development is possible, in the near future, given the marketing and emergence of Chicago as a "Global City".

7. **In-Migration, Out-Migration and Household Size –** Immigrants to the United States have, traditionally, been attracted to its large cities. As such, Chicago has accommodated a full range of immigrants. In most instances – as it is currently – this has meant larger-than-average family size, gradually transitioning into that of the average of the surrounding urban area. The current influx of immigrants to Chicago is Hispanic. The impact of their location into the neighborhoods of the North Central, North and South Central and Midway areas, has resulted in higher densities. These densities are the result of both larger family size and smaller housing units. As this population is assimilated, it is assumed that both family size and housing choice will approach those of the general population. The housing stock in these areas is – for the most part – single-family bungalows on small lots and low-rise apartments.

   A recent immigration trend is to skip over the central city, in a major urban area, in favor of a mature suburb, for an initial settlement. This pattern currently is apparent in the Chicago Metro Area. Furthermore, the immigrant group is more likely to leave the urban core for the suburbs fairly quickly, if these urban neighborhoods gentrify, become more expensive, and attract smaller households.

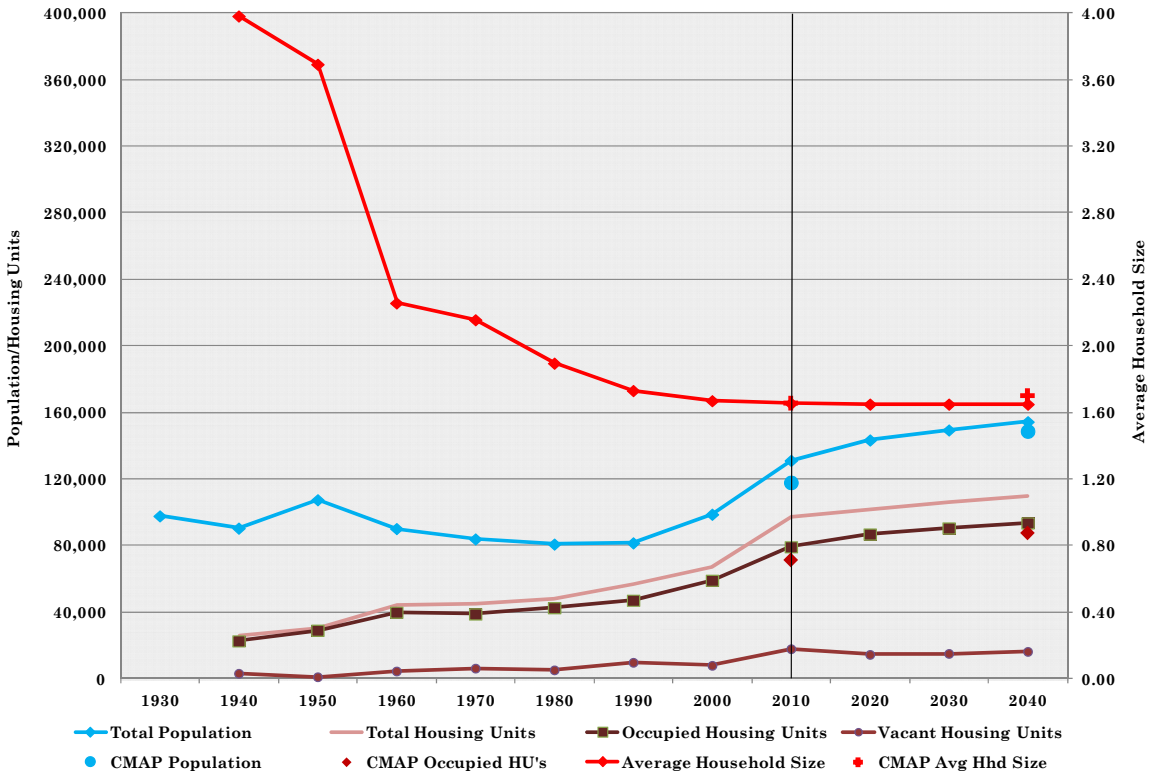
8. **Expansion of Institutions –** As the Chicago economy has undergone major structural changes, its universities, institutions and hospital/medical facilities have been major beneficiaries. And, with change, has come significant development, primarily of a high-density campus nature. The City's prime hospitals – Northwestern, University of Chicago, Rush, University of Illinois, Stroger, etc. – have expanded into their surrounding residential areas; and they are expected to continue expanding. The University of Chicago, with its medical facilities, has always been a key player in the development/redevelopment of Hyde Park, from the time of its earliest urban renewal programs. The University of Illinois Chicago was the direct result of urban renewal on the Near West Side; and, while its expansion has greatly changed its neighborhood, in some instances, it has reinforced historic preservation. Loyola and DePaul Universities are expanding their campuses on the edges of Lincoln Park and Edgewater. These are vibrant developments that benefit the surrounding areas with a wide array of jobs and local improvements; and their expansions are expected to be publicly assisted or encouraged.

To illustrate the impacts of these trends, the forecast for the three Community Area (CA) Grouping straddling the Project Corridor are presented and discussed below:

Exhibit 25 shows the population and housing trends and forecasts for the Central Lakefront Community Areas. This grouping is composed of three CA's: Loop, Near North Side and Near South Side. Considerable housing construction has occurred in this area during the last two decades. The Great Recession occurred before many major projects were completed, resulting in a vacant housing overhang. Most of this overhang has been absorbed; however relatively high

vacancy rates will continue due to the prevalence of second homes. Second homes are classified as vacant by the U.S. Bureau of the Census. Construction has resumed, but as condominium units will continue to combine to form larger units, the increase in housing units is forecasted to be less than the units constructed. Finally, average household size has already declined to almost 1.6 and is not forecasted to decline below that level.

Exhibit 25: Population and Housing Trends and Forecasts: 1930-2040
City of Chicago – Central Lakefront Community Areas



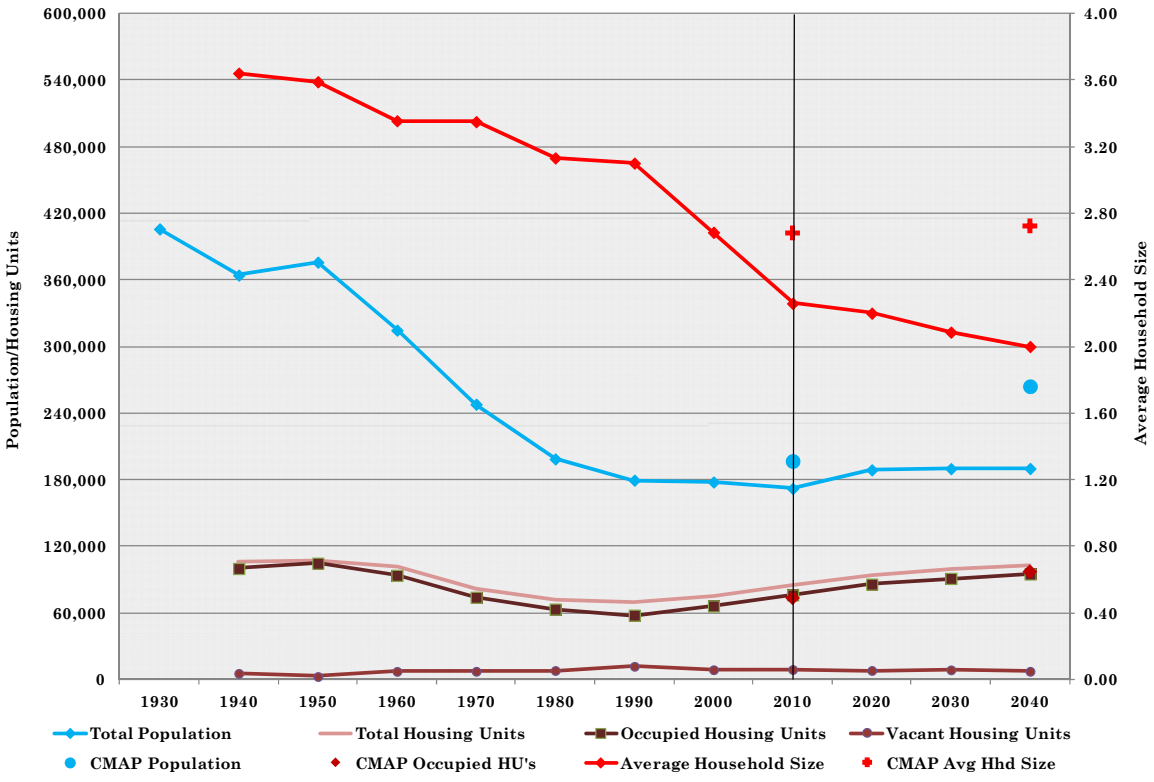


Exhibit 26 shows the past trends and forecasts for the Near West Community Area Group. This area is bounded by the Chicago River (east), California (West), North Avenue (North) and I-55 (South). The Near West benefits from the spillover development from the Central Area, which produced Presidential Towers. This area is also home to the University of Illinois Chicago, the Rush/County Medical Center and the Chicago Stadium. The older communities in this area are being revitalized, including Pilsen, with its arts and restaurants, as well as Ukrainian Village and Noble Square.

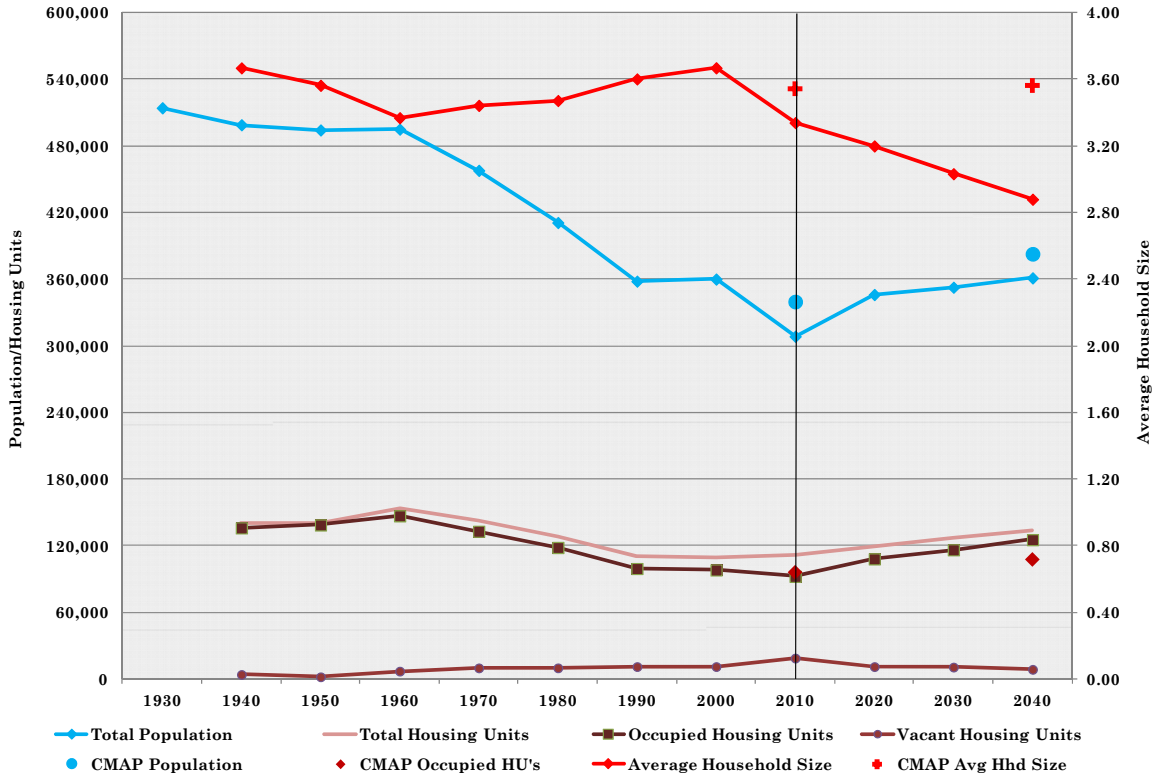

Exhibit 26: Population and Housing Trends and Forecasts: 1930-2040
City of Chicago – Near West Community Areas

Both population and average household size in these communities have been declining for decades. But, occupied housing units (i.e. households) are currently more than they were in 1970. The ACG Market-Driven forecasts to 2040 show total population increasing from 172,082 to 190,077. This is much lower than the CMAP Policy-Based forecast of 264,215, which was based, in part, on a much higher average household size and a 2010 population estimate which was nearly 25,000 higher than the Census. CMAP forecasts of Average Household Size are shown as red crosses on Exhibits 20 through 22. Household forecasts for 2040, however, are almost the same – 95,038 by ACG and 97,005 by CMAP.

Exhibit 27 shows the trends and forecasts for the West Community Areas Grouping. This area is located at the Western edge of the City of Chicago between Irving Park and the I-55. Much of this general area has been affected by highly-charged factors of racial change; the over-arching impact of the 1968 riots; and the loss of major industries – Sunbeam, Sears, Zenith, Brach, etc. There have been several attempts at revitalization: Shaw Development at Homer Square and retail revitalization at Little Village (South Lawndale). However, the needs of this greater area continue to be substantial, particularly housing and jobs.

Exhibit 27: Population and Housing Trends and Forecasts: 1930-2040
City of Chicago – West Community Areas

Total population for this West CAG has been declining since 1930. This is in spite of the fact that household size has remained approximately the same through 2000; it has started to decline post-2000. The population decline is due to the very substantial loss of housing units. Population has declined from 514,326 in 1930 to 308,605 in 2010; total housing units declined from 153,967, in 1960, to 111,202 in 2010. The ACG 2040 forecast for households is slightly higher than the CMAP forecast. However, the CMAP population forecast is higher due to CMAP's assumption that the 2040 average household size will stay approximately the same as that of 2000 (3.60). ACG's assumption is that the average household size will continue to decline (post-2000) reaching 2.80 by 2040.

Appendix A is a table presenting, by suburban township and City of Chicago Community Area Grouping (CAG), the 2010 base year data and 2040 Market-Driven total population, households, and total employment. These Market-Driven forecasts represent the I-290 No-Build Scenario. The socio-economic variables, required as input into the transportation demand model (I-290 No-Build Scenario) were derived from these township and CAG control totals.

G. Statistical Verification of the S-Curve Forecasting Methodology

As noted earlier, graphs similar to those presented as Exhibits 12-18 (preceding section) were prepared for each of 118 suburban townships (or combined townships). These graphs offer a visual verification of the strong correlation between the S-Curve equations and historical data. To quantify the statistical relationship between the S-Curve predictions and actual observed data, ACG plotted these two sets against each other. The actual Census population for each of the 118 townships for each decade was plotted against S-Curve predictions for that township and year. As the period 1920-2010 implied ten Censuses, there are 1,180 population observations to compare. The statistical observations for households were 708, as they cover the shorter period 1960-2010 (six-Censuses). The observations for employment are 545, as they cover the period 1970-2010 and do not include townships in Kendall County, as comparable employment data are not available for years prior to 2000. All the above numbers of observations are large enough to enable robust statistical analysis.

Table 3 presents the R-squared for the correlations between actual and S-Curve predictions for population, household and employment. The R-squared for all three variables are extremely good, as they approach 1.0, which indicates a perfect fit of the data. The R-squared are consistently high for the longer (1920-2010) period, as they are for the shorter (1960-2010, 1970-2010). It is the household statistic, however, that fares best, albeit slightly; at 0.991 (1960-2010) and 0.992 (1970-2010); these are almost perfect correlations between forecast and actual growth. As noted earlier, land availability controls housing construction and, therefore, households. As hypothesized earlier, it is logical to expect better predictions of households than population, using the S-Curve methodology.

Table 3. Actual Versus S-Curve Predictions

Factor	Period	Observations	R^2
Population	1920-2010	1,180	0.975
Population	1960-2010	708	0.977
Households	1960-2010	708	0.991
Employment	1970-2010	545	0.971
Population	1970-2010	545	0.979
Households	1970-2010	545	0.992

Exhibits 28 and 29 show the plots of actual population versus S-Curve-predicted population for the period 1920-2010 and 1960-2010, respectively. The 28 significant outliers in the latter graph were reviewed. Of these, the S-Curve under-estimated the population of 17, 14 of which were mature, or nearing-maturity, townships in 1960 or 1970. The high birth rates, followed by large average household size, caused these 14 observations to be underestimated. Of the 11 outliers where the S-Curve over-estimated the population, five were Berwyn and Cicero, in 1970, 1980 and 1990. During this period, these two mature townships included many older householders; but had not yet gone through a generational shift. The generational shift for these two townships occurred in the following decade or two and their actual populations approached S-

Curve-predicted. Another five over-estimated outliers are mature townships in 2010 which are on the verge of generational shift.

Exhibit 28: Actual Population vs. S-Curve Predicted: 1920-2010

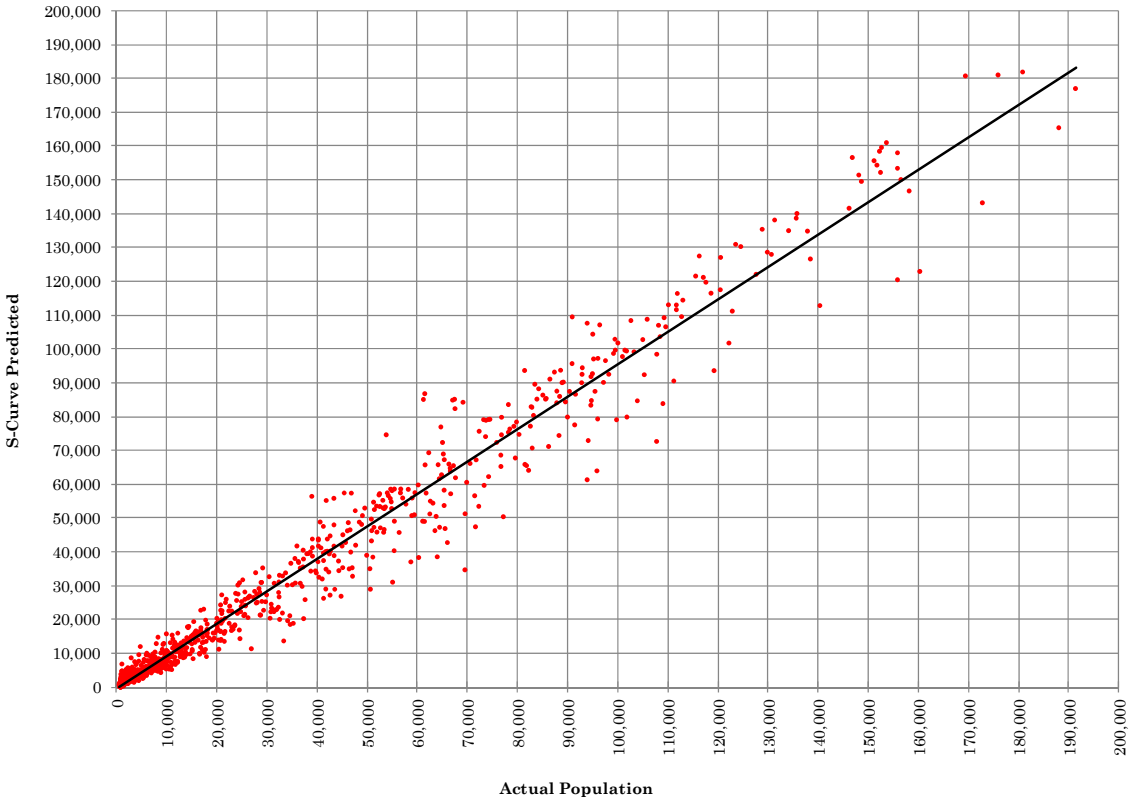

Exhibit 29: Actual Population vs. S-Curve Predicted: 1960-2010

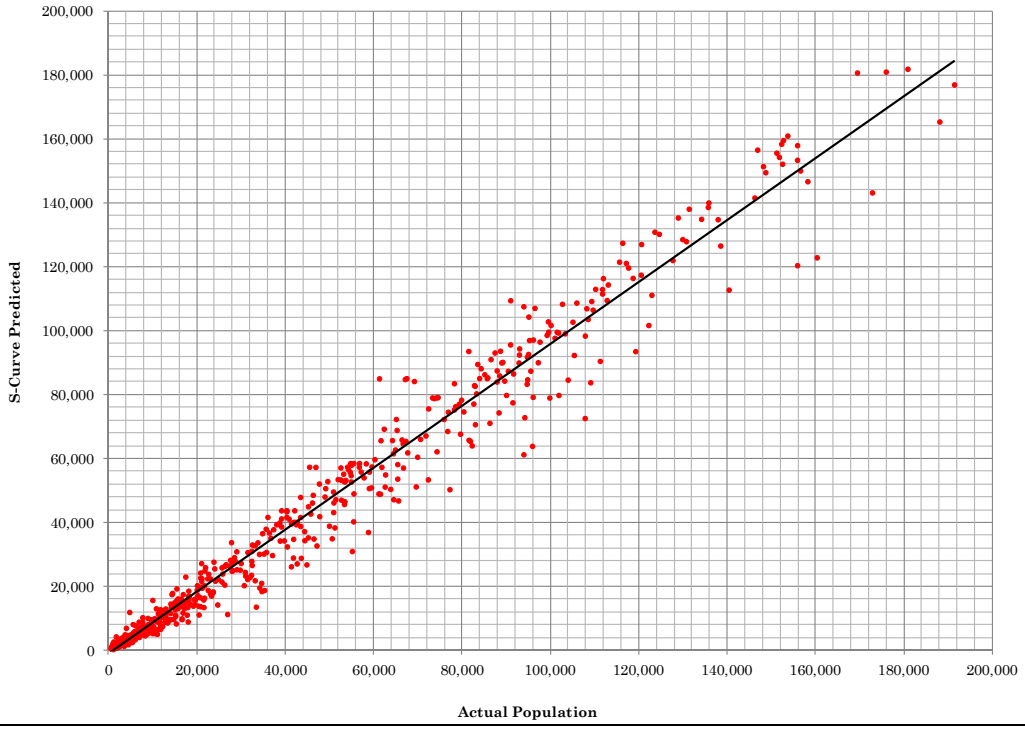

Exhibit 30 shows the plot for actual households versus S-Curve-predicted households for 1960-2010. The graph contains virtually no significant outliers and these few outliers are random. It is for this reason, that ACG considers households to be the most-reliable and accurate forecast factor for regional growth – at township or similar size geographic units using the S-Curve methodology.

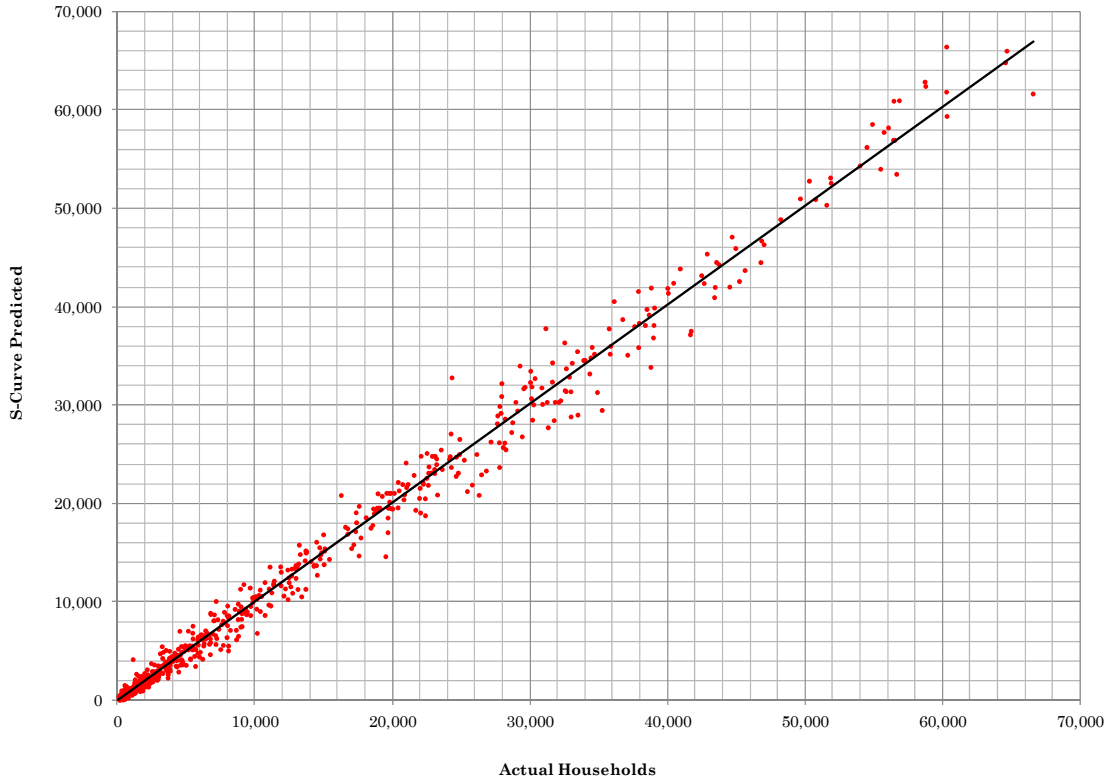
Exhibit 30: Actual Households vs. S-Curve Predicted: 1960-2010



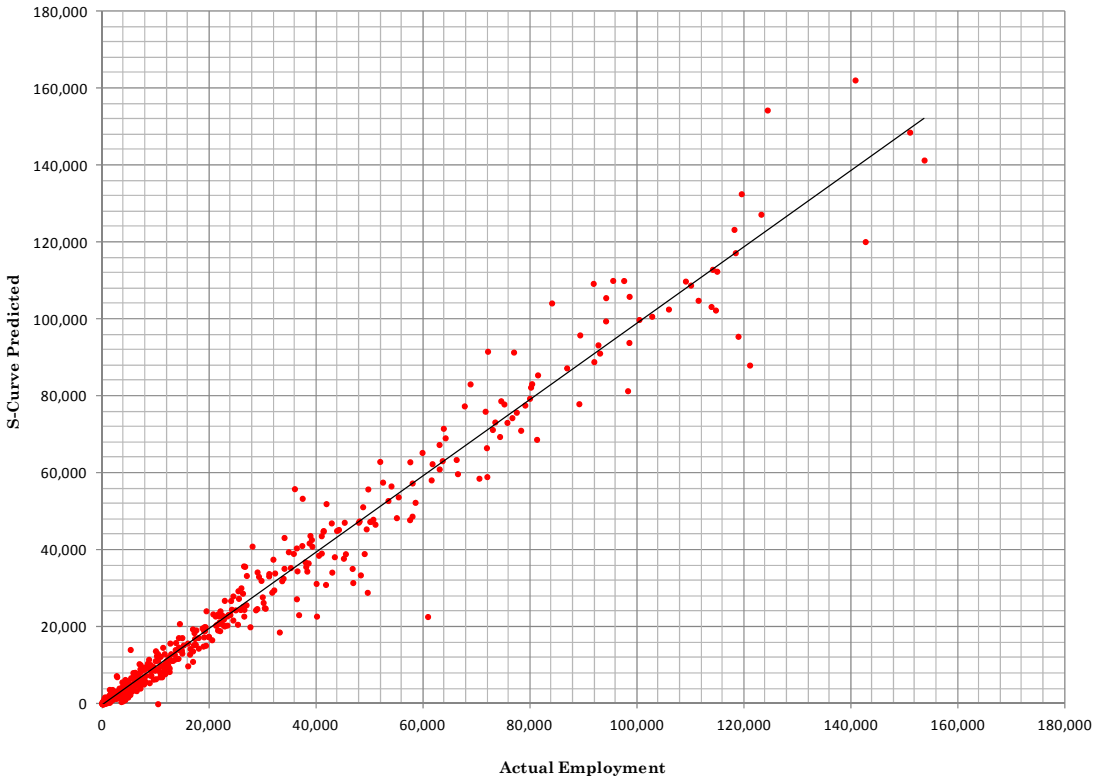


Exhibit 31 shows the graph for actual employment versus S-Curve-predicted employment for 1970-2010. Its R-squared, of 0.971, is the lowest, among the variables tested, but is still robust. Most of the outliers, above the predicted line, are mature townships with high employment (e.g. 2010 York, 2010 Elk Grove, 2010 Aurora) which suffered significant employment losses due to the Great recession. Most of the outliers, below the prediction line, are townships during their very fast growth periods (e.g. 1980 Elk Grove, 1990 Schaumburg).

Exhibit 31: Actual Employment vs. S-Curve Predicted: 1970-2010

3.0 The CMAP/NIPC Socio-Economic Forecasts: Historic and Comparison with I-290 Market-Driven Forecasts

A. Background

The Chicago Metropolitan Agency for Planning (CMAP) and its predecessor agency, Northeastern Illinois Planning Commission (NIPC) have been generating socio-economic forecasts as input into transportation planning since the mid-1960's. The methodology for generating these socio-economic forecasts evolved, reflecting improvements in the state of the profession, changes in federal regulations, and Federal court decisions relating to EIS studies.

Starting in the mid 1990's and extending to 2010, the NIPC and CMAP socio-economic forecasts included the following characteristics:

- Incorporated commonly-accepted planning principles – e.g. encouraging residential infill and adaptive reuse of sound structures; encouraging high-density development near high-accessibility transportation nodes and transit stations; avoiding development in environmentally-sensitive areas; providing and/or protecting adequate spaces for public facilities (schools, parks, local streets, etc.)
- Recognized and reflected the market forces that influence and shape urban development in the Chicago Region.
- Developed planning objectives in cooperation with local and county planners and officials, ensuring adherence to local regulations and ordinances.
- Included two sets of socio-economic forecasts: one, reflecting a "No-Plan" scenario; and, a second, developed following the adoption of the Regional Transportation Plan (RTP) and referred to as the "Plan" or "Plan-Build" scenario.

The last comprehensive socio-economic forecasts, developed in accordance with the above principles, was that generated by NIPC for the 2030 RTP following the release of the 2000 Census results. That set of socio-economic forecasts was updated in 2006 and used by CMAP for the update of its 2030 RTP. Those forecasts remained the official CMAP forecasts until the GO TO 2040: Comprehensive Regional Plan, published late in 2010.

The CMAP 2040 socio-economic forecast represented a major departure from prior CMAP/NIPC forecasting methodology. It is a "wholesale shift to scenario-based evaluation and its intentional reliance on forecasts that reflect implementation of preferred regional planning strategies. The current official CMAP forecasts are for the year 2040 and reflect the expected outcome of the preferred regional scenario adopted by the CMAP Board."[8]

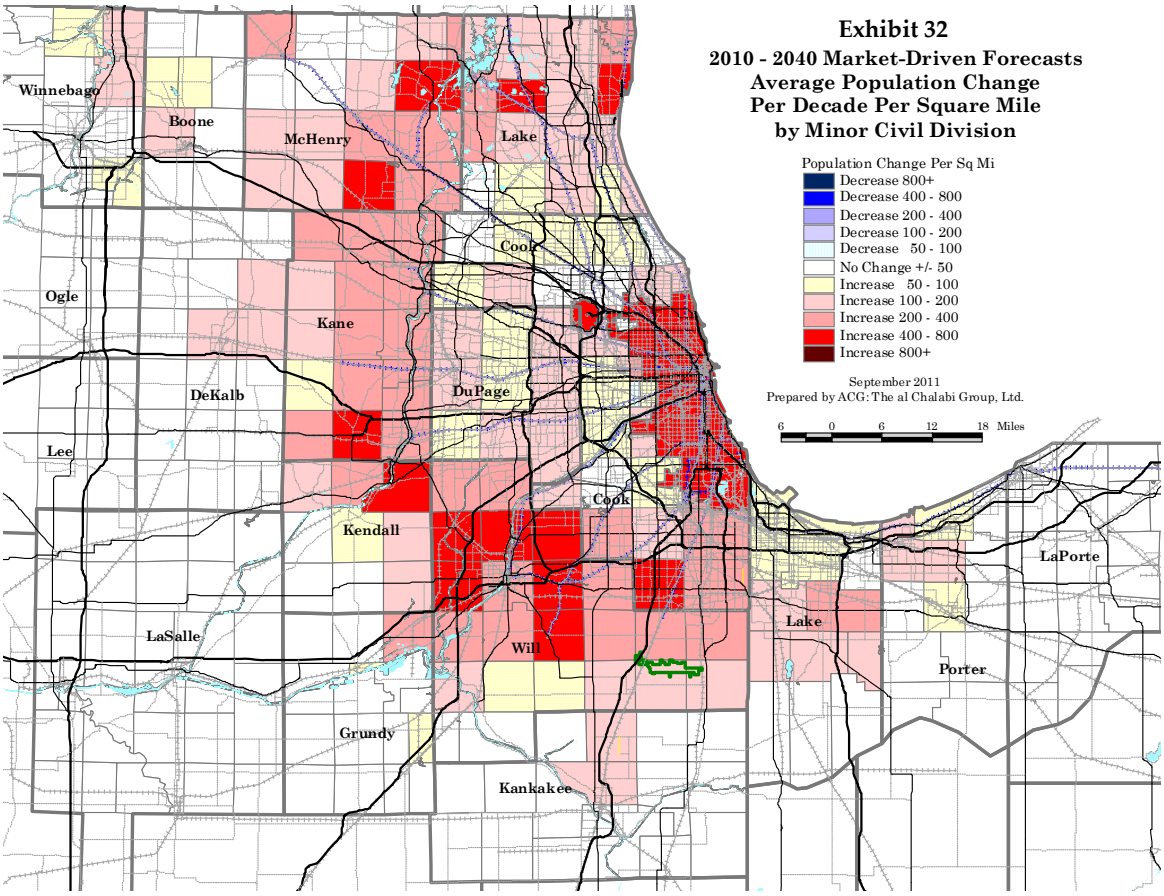
Recognizing that all intended Policy-Based results may not materialize, CMAP opted not to adopt its forecasts as the official forecasts to be used for infrastructure planning studies. The

[8] "CMAP Forecast Principles", Internal Memorandum, April 2011.

CMAP staff noted that such planning studies would be permitted to develop their own forecasts, provided that such forecasts use reasonable methodologies and acknowledge their differences from the CMAP forecasts. The CMAP principles for generating the alternative forecasts were discussed in Section 1.0.

The differences between the NIPC/CMAP 2030 and the CMAP 2040 forecasts are, themselves, the result of two different approaches to forecasting. The first includes market-driven forecast principles and also reflecting local plans and preferences; whereas, the second represents a policy-based forecast channeling development within the policies prescribed in the GO TO 2040: Comprehensive Regional Plan.

CMAP initially generated a "Reference Scenario" forecast for 2040; it assumed current trends for the socio-economic forecasts and no transportation project, a "No-Plan" scenario. The CMAP 2040 Policy-Based forecasts were developed as part of the "Preferred Scenario" development, which was completed prior to identifying the major transportation project or finalizing the Transportation Plan. Following the adoption of its GO TO 2040 Plan, CMAP opted not to revise its forecasts. The implied assumption was that the Policy-Based forecasts, which reflected the desired development, would be the same regardless of which major transportation projects were adopted and/or implemented.



As is stated in the Introduction, the 2040 Forecast, prepared by the PB/ACG team for the I-290 No Build Scenario, are more closely related to extrapolations of the NIPC/CMAP 2030 forecast than to the CMAP 2040 forecasts, as both (NIPC and ACG) share the same market approach to forecasting and consider local zoning and prevailing densities as the basis for estimating the holding capacities of townships.

B. Comparing the I-290 Market-Driven No-Build Forecast with the CMAP Policy-Based Forecast (2010)

Exhibit 32 shows the total population change between 2010 and 2040 of the Market-Driven forecast for the I-290 Study. The data is presented as change per decade per square mile, by township, to provide a more-consistent basis for comparison with prior exhibits. The general picture is of a central city (Chicago) remaining vibrant and growing; a south portion of the region growing to levels previously experienced in the north and west sections of the metropolitan area; substantial growth, creating higher densities, at the region's edges; and an inner suburban area with moderate growth.

Exhibit 33 shows the CMAP Policy-Based forecast distribution of population for 2010-2040. Under this scenario, the City of Chicago and the North Shore lakefront provide a major part of the region's growth. These areas and close-in counties (DuPage, North Cook) are allocated growth which would appear to require substantial increases in density. For this density increase to materialize would require considerable replacement of existing stock, since many areas already are developed to mature levels. The City of Chicago grows to 3,303,768 by 2040. This

increase, of 608,170 persons, is nearly double the increase of the Market-Driven forecast. There are major population increases in the close-in townships of Will, McHenry, Kane and Kendall counties; but, growth beyond these areas is limited or contained. Exhibit 34 shows the difference in forecasts of the two population forecast alternatives.

Table 4 compares these two forecasts for population and employment for 18 counties and the four Cook sub-county areas in the Illinois/Indiana parts of the extended Chicago region.

The most significant reason for the differences in township population forecasts, between the I-290 Market-Driven (I-290 No Build) and the CMAP Policy-Based forecasts, relates to the above-referenced differing density assumptions for the fully-developed inner suburbs. Most of the housing stock in these inner suburbs, designated for redevelopment by CMAP, is in excellent condition and has high market value. Furthermore, local zoning ordinances, in most of these areas, do not allow for such high-density redevelopment. Accordingly, substantial redevelopment of these fully-developed inner suburbs is not likely, given current local policies and prevailing market conditions.

However, there are other reasons for the differences between the above two population forecasts. The CMAP forecasts were completed prior to the release of the 2010 Census. The initial 2010 population estimates, by CMAP, for many of these fully-developed townships were higher than those shown in the 2010 Census. Once the Census results were released, CMAP lowered its 2010 base year data, but not its 2040 forecasts. Furthermore, the 2010 Census results revealed smaller households than initially assumed by CMAP. Within the City of Chicago, both forecasts (I-290 Market-Driven and CMAP Policy-Based) have similar household forecasts for 2040, but population forecasts which are significantly different; the difference is due mainly to differing household size. CMAP's average household sizes are closer to 2000 data than the 2010 Census.

* Dated March 15, 2010 and used for the I-290 transportation modeling of the I-290 "No-Build" Scenario.

There are two reasons for the differences between the I-290 Market-Driven and CMAP Policy-Based employment forecasts. The first and more-important reason relates to the definitions and sources of employment data. The primary source for the CMAP/NIPC employment data is the Illinois Department of Employment Security (IDES). The IDES employment data has been historically used by CMAP/NIPC because of the detailed place of work information. CMAP/NIPC compiled its employment data by geo-coding the IDES addresses to quarter-sections and aggregating the employment data to townships and municipalities. Corrections were also made for corporate headquarters reporting. The IDES data does not include employment not covered by unemployment insurance.

The source of the I-290 Market-Driven employment data and forecasts is the Bureau of Economic Analysis (BEA), of the U.S. Department of Commerce, which publishes employment data, by county. The BEA employment data is the most-complete measure of all full-time and part-time jobs by place of work. Unlike the IDES employment data, it includes all proprietors, agricultural workers, household workers and miscellaneous workers (including those paid in cash). The BEA employment is almost identical to that produced by the National Income and Product Accounts (i.e. data used in Input/Output models); and in the Woods & Poole Economics forecasts used by many regions and states, including Illinois. BEA employment data are available, by County, for a period dating back to 1969. Recently, several commercial resources have started making this data available by township; and ACG has obtained such data for 1990, 2000 and 2010. ACG checked this data against official BEA data, by county, and undertook minor adjustments to ensure compatibility with county data. BEA employment estimates, by township, were generated by ACG using NIPC IDES data and BEA county control totals. Differences between IDES and BEA employment is increasing as both the number of self-employed and the cash economy continue to increase. Since the employment estimates are used as input to the travel forecasting model to estimate work trips, the BEA's more comprehensive employment estimate provides a more representative starting point for travel forecasting.

The second reason for the differences in employment forecasts (I-290 vs. CMAP) is due to differences in market trends vs. CMAP policies. Market trends allow for townships with high concentrations of jobs to continue to grow provided expansion space is available and locational advantages are still present. One of the CMAP policy goals is to balance jobs with nearby residences (workers). Accordingly, job growth in high job townships (e.g. York Township) is discouraged and reduced from historic trends even if vacant space is available.

C. Why Use the Market-Driven Forecasts for the I-290 EIS Study?

The Federal Highway Administration (FHWA) has issued guidelines on the application of travel and land use forecasting for NEPA/EIS studies[9]. Among the FHWA requirements:

[9] Interior Guidance on the Application of Travel and Land Use Forecasting in NEPA", Federal Highway Administration, March 2010.

- Recent available data should be used – not using 2010 Census data would jeopardize the validity of the EIS forecasts, which was not included in the CMAP GO TO 2040 forecasts (2010).
- "Understanding existing conditions and trends." The Market-Driven forecasts and their S-Curve Model reflect, almost exactly, the growth of the Region during the past 90 years (documented by ten decennial Censuses). The Policy-Based forecasts represent a new methodology that does not cite or explain past trends; furthermore, its intention is to change past trends.
- Inventory land with development potential: This step identifies undeveloped and underdeveloped open land and, in combination with environmental restrictions and zoning regulations, quantifies land available to absorb growth. The Market-Driven forecasts use this principle to determine the household, population and employment holding capacities of each township. The Policy-Based forecasts are not constrained by such factors.
- Assign population and employment to specific locations: This step uses land availability, the cost of development, and the attractiveness of various areas to estimate the amount and type of growth that will occur in each zone. Again the Market-Driven forecasts and their S-Curve models reflect this FHWA requirement.

The CMAP staff recognized, initially, the special requirements of FHWA for NEPA/EIS studies. This recognition was one of the reasons why the CMAP staff allowed (and even encouraged) the development of alternative forecasts for project-specific studies. The CMAP staff established guidelines for preparing these alternative forecasts. The I-290 Team adhered to these CMAP guidelines in developing the Market-Driven socio-economic forecasts.

Also, the CMAP GO TO 2040 forecasts scenarios did not include a No Build scenario consistent with NEPA requirements for use in project level analysis. CMAP had developed a "Reference Scenario" as a baseline to evaluate over 100 proposed major capital improvements. Because the policy direction of the GO TO 2040 Plan had not yet been established, the Reference Scenario assumed no action, based on the continuation of current socioeconomic and land use trends and no additional transportation infrastructure in 2040. Thus, no major capital projects were assumed and the socio-economic forecasts were based on a straight extrapolation of previous 2030 forecasts. This CMAP Reference Scenario essentially represents a no plan scenario.

4.0 The I-290 Build Socio-Economic Forecasts

A. Overview

The general methodology employed in the Build/No-Build analysis recognizes the important interrelationships between transportation systems and urban development (i.e., accessibility influences locational decisions which, in turn, influence accessibility). In selecting a location for an activity (e.g. industrial plant, office building, residence) the decision-maker considers the accessibility of the various potential sites to concentrations of various activities (e.g. labor force, job concentrations, schools, recreational activities). This fact is general knowledge to every market analyst, real estate broker and developer; and is used in conducting their day-to-day business. It also is understood that improving the access of developable or redevelopable sites increases the development potential of those sites, attracting development (residential, commercial/industrial, institutional) that may have occurred elsewhere in the region.

The general method employed, in this analysis, compares the existing accessibility with that provided by the proposed improvements. The I-290 Phase 1 Study uses as its baseline (2010-2040) forecasts, the Market-Driven No Build forecasts prepared by ACG and whose methodology and results were described, previously, in Section 2.0 of this report.

The Market-Driven No Build baseline forecasts reflect 2040 conditions assuming no I-290 Eisenhower Expressway improvements (no additional lanes on I-290) and no Blue Line Forest Park Branch transit extension. The No Build baseline forecasts, however, do assume the implementation of other major capital transportation projects included in the approved, financially-constrained, metropolitan transportation plan for the region (outside of the Study Area), and the Transportation Improvement Program for the region.

B. Build Forecast Methodology

There are many factors influencing the distribution of households, population and employment within a metropolitan region. Among these factors are:

- Availability and cost of developable land.
- Quality of education.
- Availability and quality of other urban services, e.g. water, sewers, public safety, open space.
- Quality of the landscape, e.g.: terrain, tree coverage, scenery and waterfront.
- Accessibility considerations, especially between jobs and labor.

The introduction of new transportation facilities and/or services changes the accessibility of an area and directly impacts population, household and employment forecasts. The I-290 analysis retains the accessibility measures and methodology for determining them that were used, previously, in the studies cited in the Overview. This methodology compares the changes in

highway travel times, only. This methodology is used for generating the socio-economic forecasts for the first of the I-290 Build Scenarios – the highway improvement only.

Because the second of the I-290 Build Scenarios includes both highway and transit (Blue Line) extension, it was determined that Composite Accessibility impacts must be used to measure changes in accessibility and developmental impacts for this scenario. To ensure that the results of this composite forecast are reasonable, they are compared with those of the Highway-Only Accessibility analysis, which technique has been accepted in prior EIS analyses, and which may be construed as the state of the profession. Two composite measures of accessibility were prepared, evaluated and compared to the Highway travel time measures; these two measures are "General Cost" and Travel Time Equivalent". The latter measure (travel time equivalent) was selected for the combined highway/transit improvement as its highway component better-approximated the travel time impact of the highway-only improvements.

The percent change in accessibility is applied to changes in household and employment forecasts (2010-2040) to generate the impact of the transportation improvement. It should be noted, that the sum total of positive impacts (more growth) is set to equal the sum total of negative impacts (lesser growth). The implication of this assumption is that the total regional growth (within the transportation modeled region) is unchanged – i.e. transportation improvements cause redistribution of socio-economic activities rather than generating additional regional growth. This assumption has been imposed, by IDOT and Federal agencies, on Build/No Build analyses to discourage the generation of exaggerated benefits for any given project. It is true that some major transportation projects do cause an increase in the accessibility of the region, as a whole; such projects may imply additional growth for the region. However, the Build/No Build analysis guidelines do not allow for changing the regional growth totals. The Build/No Build analysis is intended to measure only the redistribution impacts of the project.

C. Measuring Accessibility

Each Transportation Analysis Zone (TAZ) has an accessibility index which measures the travel impedances between that TAZ and other TAZ's within a region. The introduction of a new transportation facility changes this accessibility. TAZ's which improve their accessibility to jobs or labor force become more attractive for residential or industrial/commercial developments, respectively. The reverse also is true. The first operational issue is to generate indexes for measuring accessibility to jobs and labor force. These generated indexes:

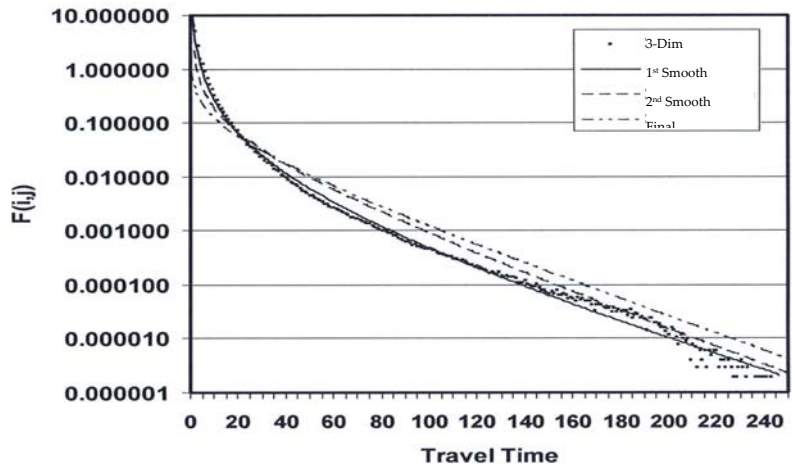
- have a theoretical basis
- can be calibrated using historical data
- can be forecasted using acceptable models

In selecting jobs, workers put more emphasis (weight) on jobs closer to their residences than on jobs farther away. The varying weights are the functions of the inter-zonal impedances in a

gravity-type trip distribution model. The method for calibrating this function is described in Appendix B – Travel Time Impedance Estimation.

Exhibit 35, below, shows these weights, $F_{i,j}$s, as functions of travel time. The sum product of these weights and the travel times from a given origination zone to all destinations generates an accessibility index for the origination zone for a specified transportation network. The percent change in the accessibility index for a zone, given two alternative transportation methods, provides the basis for calculating the household or employment forecast differential of these two alternatives. This method for measuring changes in accessibility is used for the highway-only improvement.

Exhibit 35: Final Weight – $F_{i,j}$s



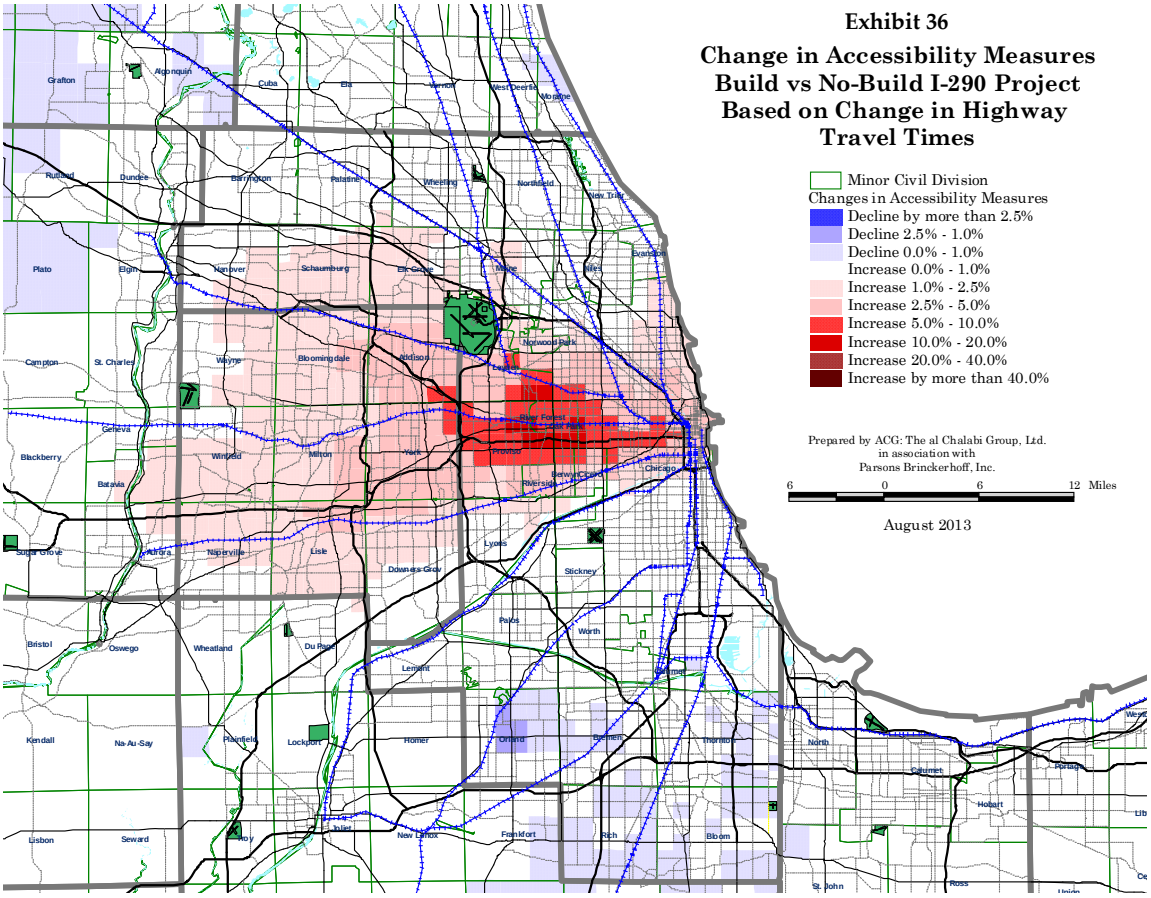


Exhibit 36 shows the percent change in accessibility measures, by TAZ, between the I-290 Build and No Build highway-only improvement scenarios. As anticipated, the TAZ's for the Build Alternative that experience the most increases are those in the vicinity of the I-290 improvements, followed by those along the balance of the corridor and radiating from there along existing expressways. TAZ's which experience relative decline in accessibility are those farther out and away from the proposed improvement.

For the combined highway and transit improvement, the percent changes in accessibility measures, as derived from the travel time equivalent for each of the highway and transit modes, are calculated for each TAZ. These changes in accessibility are adjusted to reflect the modal share for each TAZ. Such adjustments are necessary to eliminate distortions caused by changes in transit accessibility in TAZ's with little or no transit usage.

D. Impact of Changes in Accessibility Indexes on Residential Development (Household and Population)

Improving access to jobs makes a TAZ/township more attractive for residential development, assuming all other factors influencing development are held constant. Applying the changes in the accessibility measures, discussed in the preceding section, to the 2010-2040 forecasted baseline growth in households, yielded an initial redistribution of households representing the impact of building the proposed project. Following this initial redistribution, two levels of adjustments were made.

- **Setting a ceiling** – The holding capacity (households) for each TAZ is calculated using such criteria as prevailing densities and available developable land. Households in excess of these capacities are redistributed to nearby zones experiencing increases in accessibility to jobs – a large number of TAZ's required this adjustment.
- **Balancing the accessibility-induced adjustments –** The sum of the induced growth in households and population, as adjusted by the preceding two steps, is balanced by reduction in growth elsewhere in the Chicago CMSA. The magnitude of the reduction in growth, is determined by the change in the accessibility index in each TAZ.

As stated earlier, balancing the increases with decreases in forecasted growth is a policy assumption of the Build/No Build impact analysis model. Not undertaking such balancing implies more growth in the Chicago CMSA at the expense of other regions within the U.S. There is no basis for assuming such transfers among regions in the absence of a nationwide, single transportation modeling effort. It should be noted that, in the case of the I-290, impact analysis, the accessibility of the Region, as a whole, increases slightly. Accordingly, the increase in household and population forecasts, prior to the balancing process, do exceed the reductions. To achieve the desired balance, areas whose accessibility improved more than the regional average attracted additional residential development from the areas whose accessibility declined or increased at levels below the regional average.

Exhibit 37 shows the impact of the Highway Improvement Component of the proposed project on the redistribution of population, by TAZ. Population impacts of the I-290 are derived by multiplying the household impacts by the average household size, by TAZ. The TAZ's receiving most of the additional growth in population are those experiencing significant changes in accessibility. TAZ's experiencing lesser growth are the TAZ's experiencing reduction in accessibility or increases below the regional average, but which are forecasted to experience considerable 2010-2040 growth in households under the Baseline Alternative. It should be noted, that no TAZ would experience an actual decline in households during the period 2010-2040.

Exhibit 38 shows the impact of the Transit Improvement Component of the I-290 Study on the redistribution of 2010-2040 population. The combined impacts of both the Highway and Transit Components, by County/Cook Subdivisions, are shown on Table 5. This table shows these impacts, by county and sub-area of Cook, for the Seven County (CMAP) area total and for 14 total or partial external counties of the region.

E. Impact of Changes in Accessibility Indexes on Employment Distribution

Whereas improving a TAZ's accessibility to jobs makes it more attractive for residential development, the opposite also is true. Improved accessibility to residential concentrations implies better access to labor and consumption, making the area more attractive to industrial and commercial development. In the case of the I-290 Study, the improved accessibility provided by it makes these two factors equally responsible for growth.

The methodology for determining the impact of changes in accessibility indexes on employment distribution is the same as that used for residential re-distribution. Once the distribution of additional growth in employment was completed, a balancing process was undertaken, similar to that described for studying the residential impacts, as discussed earlier. Again, the total 2040 employment forecast for the transportation modeling region is assumed to remain unchanged.

Exhibit 39 shows the impact of the Highway Component of the I-290 Build Alternative on the redistribution of employment. The TAZ's that are forecasted to receive additional growth (above the baseline forecast) in employment are concentrated. Most of the TAZ's with positive impact (more growth in employment) is concentrated within the employment centers located along the I-290 alignment or along expressways or arterials connecting to I-290. Most of the TAZ's with negative (lesser) growth are located at a distance from I-290. It should be noted, again, that no TAZ is forecasted to experience a loss of employment as a result of the proposed project, only reduction in the forecasted growth. However, there are TAZ's forecasted to lose employment as a result of other factors; and these losses are reflected in the baseline forecasts. The overall impact of the proposed project is to attract both population and employment to the center of the Chicago Region.

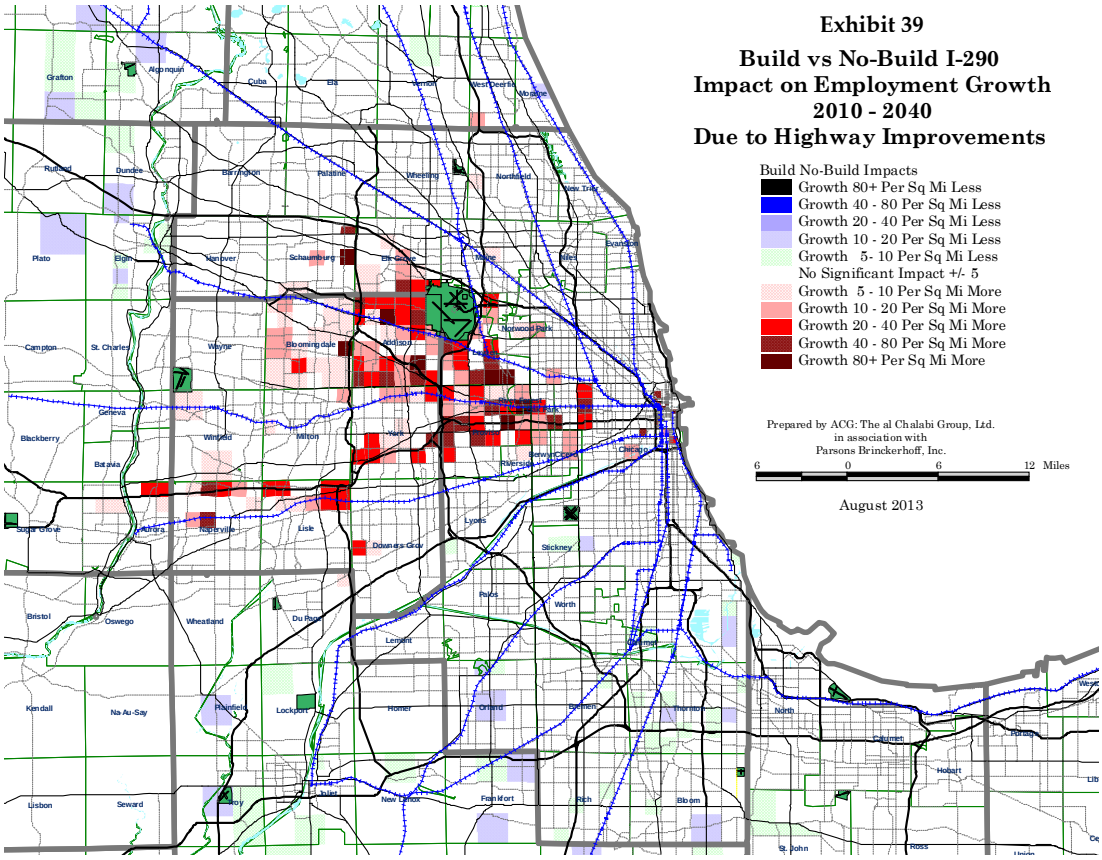

Exhibit 40 shows the impact of the Transit Improvement Component of the I-290 Study on the redistribution of employment growth. The transit improvement consists of the extension of the CTA Blue Line to Mannheim Road and the introduction of express bus service connecting to the Blue Line extension. The positive employment impacts occur at the location of the new stations and the termini of the express bus service.

Table 6 shows the combined employment impacts of both the highway and transit components of the proposed project. These impacts are shown for the seven-county CMAP region and 14 external counties.

F. Socio-Economic Forecast Files as Delivered to Parsons Brinckerhoff Inc., as Input into the Transportation Modeling Process

In the summer of 2013, ACG prepared and submitted to PB, three sets of socio-economic forecasts for 2040. The first of these sets represented the I-290 No Build Scenario; the methodology and principles guiding the preparation of this set are detailed in Section 2.0 of this report. The second set represented the I-290 Build scenario assuming the implementation of

only the highway component of the I-290 Study. The third set represented the I-290 Build Scenario assuming the implementation of both the highway and transit components of the proposed project. The two Build forecasts were prepared in accordance with the methodology described in the preceding section of this section.

Each of these three socio-economic files contained the 2010 (base year) and 2040 (forecast) values of 11 variables for each of 16,676 transportation sub-zones in the 21-County CMAP transportation modeling area. With few exceptions, the sub-zone size varied from quarter-section (1/4 square mile), within the CMAP region, to township in some external counties. The variables are required input into the CMAP transportation modeling package used by PB to estimate future transportation demand and evaluate current and future performance of the region's transportation system and facilities with and without the proposed I-290 improvements. The 11 variables, for each sub-zone, of the socio-economic forecasts files are:

- Number of households
- Adults per household
- Workers per household
- Children per household
- Children 12-15 years old as percent of all children
- Average household income as ratio of regional average
- Workers in non-institutionalized group quarters
- Non-workers in non-institutionalized group quarters
- Population in institutionalized group quarters
- Total employment
- Retail employment

In generating the above variables, other variables had to be generated either as input or as reasonable checks. Examples of these additional variables include: number of adults, children, workers; average household size; average household income; and total population.

5.0 Epilogue

Almost a year following the completion of the No Build and Build forecasts for the I-290 Phase 1 Study, CMAP started the process of revising its 2040 socio-economic forecasts to reflect the 2010 Census and its 2010 land use survey results. These CMAP revisions are incorporated into their GO TO 2040 Comprehensive Regional Plan Update that was adopted in October 2014.

The updated CMAP forecasts are closer, but still higher, than the I-290 forecasts for the City of Chicago (+1.8%), Suburban Cook County (+4.8%), and DuPage County (+8), which are the main travel markets for the I-290 Corridor.

A comparison of the Study Area 2040 population and employment forecasts was also performed, as shown in Table 7. As seen in this table, the Study Area population forecasts for CMAP and the I-290 EIS are within one percent of each other. For employment, it should be noted that there are definitional differences. The I-290 EIS forecasts use the U.S. Bureau of Economic Analysis (BEA) definition of employment, while CMAP uses the Illinois Department of Employment Security (IDES) definition of employment. The BEA based employment estimate is higher than the IDES based estimate because the BEA defines employment to include the cash economy and self-employed. Therefore, the BEA definition of employment provides a more comprehensive definition of employment.

Table 7. Comparison of 2040 Study Area CMAP and I-290 No Build and Build Population and Employment Forecasts

Forecast	2040 Population	2040 Employment

I-290 Phase 1 Study Travel Time Impedance Estimation

Travel Time Impedance Estimation

The following paragraphs describe the procedure to estimate a travel time based impedance function based on northeastern Illinois-northwestern Indiana work trip data. This function is the inter-zonal impedance in a gravity type trip distribution model. The calibrated function was provided to the subconsultant responsible for the development forecasts for the project.

To estimate this function, a gravity model was calibrated to Census Transportation Planning Package (CTPP) Part III journey to work flow tables produced from Census 2000 long-form questionnaires. The estimation procedure is an iterative approach frequently used to calibrate gravity type trip distribution models to observed travel time distributions. Impedances are initially estimated, then used in a gravity model to distribute trips. The travel time distribution for these trips is compared against an observed travel time distribution and the impedances factored by the ratio of observed to distributed trips in a travel time interval. Trips are repeatedly distributed by the model and the impedances factored iteratively until reasonable agreement between the observed and distributed trips travel time distribution is achieved.

General Trip Distribution Gravity Model

The general formulation of the trip distribution gravity model consists of the following equation that relates the number of trips between zones to the travel impedance between zones.

$$T_{i,j} = a_i b_j F_{i,j}$$

In this equation: $T_{i,j}$ equals the number of trips between zone i and zone j; a_i and b_j are balancing coefficients that depend on trip productions and trip attractions respectively, and; $F_{i,j}$ is the inter-zonal impedance between zones i and j.

In a doubly constrained gravity model the trips distributed from a zone must equal the trip productions in the zone (P_i), and the trips received by a zone must equal the zone's trip attractions (A_j).

1. $$P_i = a_i \sum_j b_j F_{i,j}$$

2. $$A_j = b_j \sum_i a_i F_{i,j}$$

These three sets of simultaneous equations (the trip distribution and the two constraints) can then be readily solved using two-dimensional matrix balancing when the inter-zonal impedances $F_{i,j}$ s are known.

For gravity type trip distribution models, the most widely used mathematical relationship between the inter-zonal impedance and travel time is the Gamma function. This function has

three parameters (◎, ◎ and ◎) that permit a number of different forms for these impedance-travel time relationships, from negative exponential to near normal.

$$F_{i,j} = \alpha\, t_{i,j}^{\beta}\, e^{\gamma t_{i,j}}$$

Steps in the $F_{i,j}$ Estimation Algorithm

Several matrices must be prepared before the algorithm to estimate Fi,j can be implemented.

1. A zone to zone matrix of travel time categories is prepared. In this case, the base year I-290 peak period highway travel times are first rounded to integer minutes. All travel times greater than 250 minutes are set to 250. Intra-zonal travel times are assumed to equal two-thirds the travel time to the nearest neighbor zone. No travel times are less than one minute.
2. The auto driver, carpool, taxi, and motorcycle journey to work flows from the northeastern Illinois and northwestern Indiana CTPPs are tabulated into a table of flows between I-290 zones.
3. Zone level trip productions and attractions are summed from the CTPP trip table.
4. The travel time frequency distribution (the number of trips at travel times between 1 and 250) is tabulated from the CTPP trip table and I-290 zone to zone peak highway times.

Initial $F_{i,j}$ Estimate. An initial estimate of the $F_{i,j}$s were developed using the three-dimensional balancing module available in the EMME/2 transportation planning software. In this approach, a third constraint is specified for the modeled trip table that requires the distributed trips to match a specified travel time distribution.

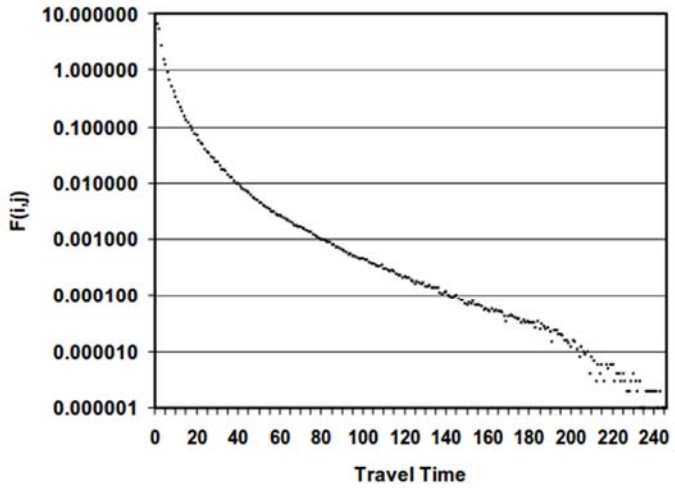
The general gravity model distribution is rewritten as:

$$T_{i,j} = a_i b_j f_{t_{i,j}} m_{i,j}$$

The $ft_{i,j}$ is the balancing coefficient for the travel time t required to move between zone i and zone j, while $m_{i,j}$ is an initial matrix to be balanced. All other quantities are as defined previously.

As described above, the $F_{i,j}$s are iteratively estimated as in a typical gravity model calibration and the initial starting estimate of the $F_{i,j}$s need only be a crude approximation. However, the best initial estimates of $F_{i,j}$ are obtained when the matrix to be balanced has cells equal to one where interchanges exist in the calibration trip table and zero for pairs of zones without movements.

The three constraints on the distributed trips are as follows:



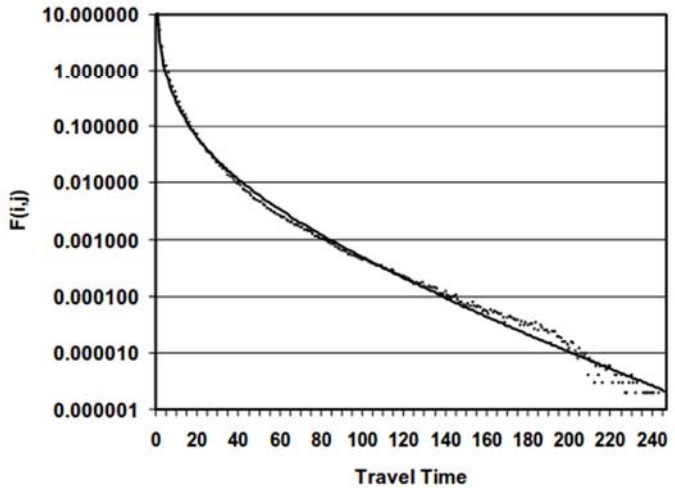
1. $P_i = a_i \sum_j b_j f_{t_{i,j}} m_{i,j}$

2. $A_j = b_j \sum_i a_i f_{t_{i,j}} m_{i,j}$

3. $P_t = \sum_{(i,j) \text{ with } t_{i,j}=t} a_i b_j f_{t_{i,j}} m_{i,j}$

The first two constraints are the same as in a doubly constrained gravity model, requiring trips sent to equal productions and trips received to equal attractions. The third constraint states that the summed distributed trips for all zone pairs at travel time t must equal the number of trips specified in the travel time frequency distribution at travel time t. The four sets of simultaneous equations are again solved iteratively by the three-dimensional balancing algorithm in EMME/2.

FIGURE 1 Initial Estimated $F_{i,j}$s from Three-Dimensional Balancing



The resulting balancing coefficients ($ft_{i,j}$s) for the third travel time distribution constraint are initial estimates of the $F_{i,j}$s. Figure 1 is a plot of these estimated $F_{i,j}$s for the estimation.

Smoothing of $F_{i,j}$ Values. A Gamma impedance function is next fit to the above $F_{i,j}$ data points. Least squares regression is used to fit the natural log of the Gamma function values to the above $F_{i,j}$ data points, smoothing the $F_{i,j}$ values to a continuous function of travel time. The function estimated by the least squares regression is:

$$Ln(F_{i,j}) = Ln(\alpha) + \beta Ln(t_{i,j}) + \gamma\, t_{i,j}$$

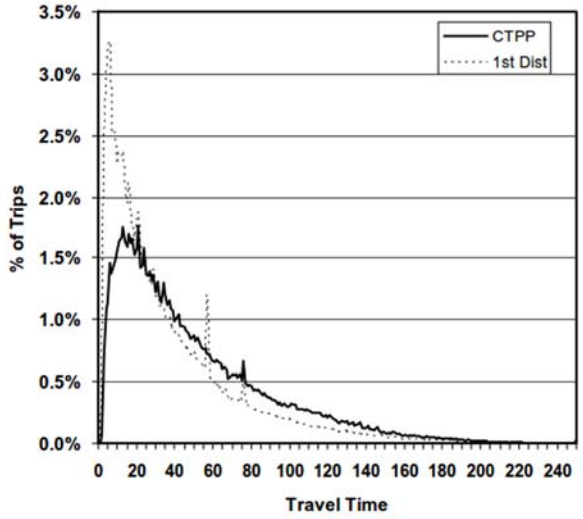
FIGURE 2 First Smoothed $F_{i,j}$s

The resulting regression equation is plotted against the initial $F_{i,j}$ data points in Figure 2. The values for the three Gamma function parameters α, β, and γ estimated by the regression are 25.3, -1.8 and -0.03.

First Trip Distribution. Base year person auto work trips were distributed using a gravity model with the smoothed $F_{i,j}$s. The travel time distributions for the CTPP highway commute trips and the I-290 auto work trip distribution are shown in Figure 3. There are clearly too many short distributed trips compared to the CTPP travel time distribution.

Factoring and Second Smoothed $F_{i,j}$s. The $F_{i,j}$s were adjusted by the ratio of observed to distributed trips for each minute travel time category. Since the CTPP and the I-290 trip tables have different totals the ratio was calculated from the proportions of trips at a given travel time. The Gamma impedance function was then re-estimated using the factored $F_{i,j}$s as data points, and these second smoothed $F_{i,j}$s are shown in Figure 4. The new values estimated for α, β, and γ are 2.4, -1.0 and -0.03. Note that these parameters are such that the $F_{i,j}$s are reduced for short trips and increased for longer trips, which is consistent with the differences in the observed and distributed trip travel time distributions.

FIGURE 3 Travel Time Distribution for CTPP and First Distributed Trips



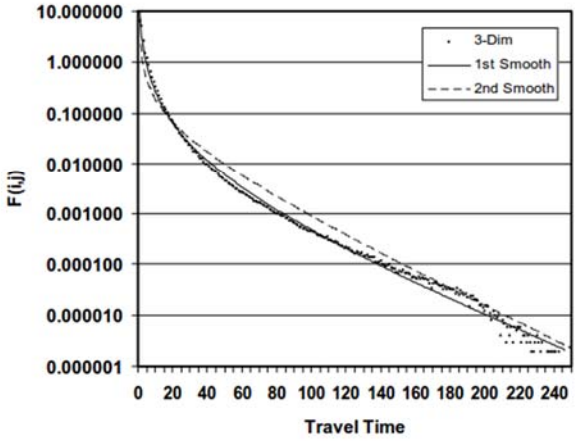


FIGURE 4 Second Smoothed $F_{i,j}$s

Second Trip Distribution. Trips were redistributed with the revised Gamma impedance function and the revised travel time frequency distribution is shown in Figure 5. Reasonable agreement between the two travel time frequency distributions is achieved after two iterations.

Factoring and Final Smoothed $F_{i,j}$s. The factoring and smoothing of the $F_{i,j}$s was carried out a third and final time. The results are shown in Figure 6 for the final estimates of the values for the three parameters α, β, and γ which are 0.9, -0.7 and -0.03.

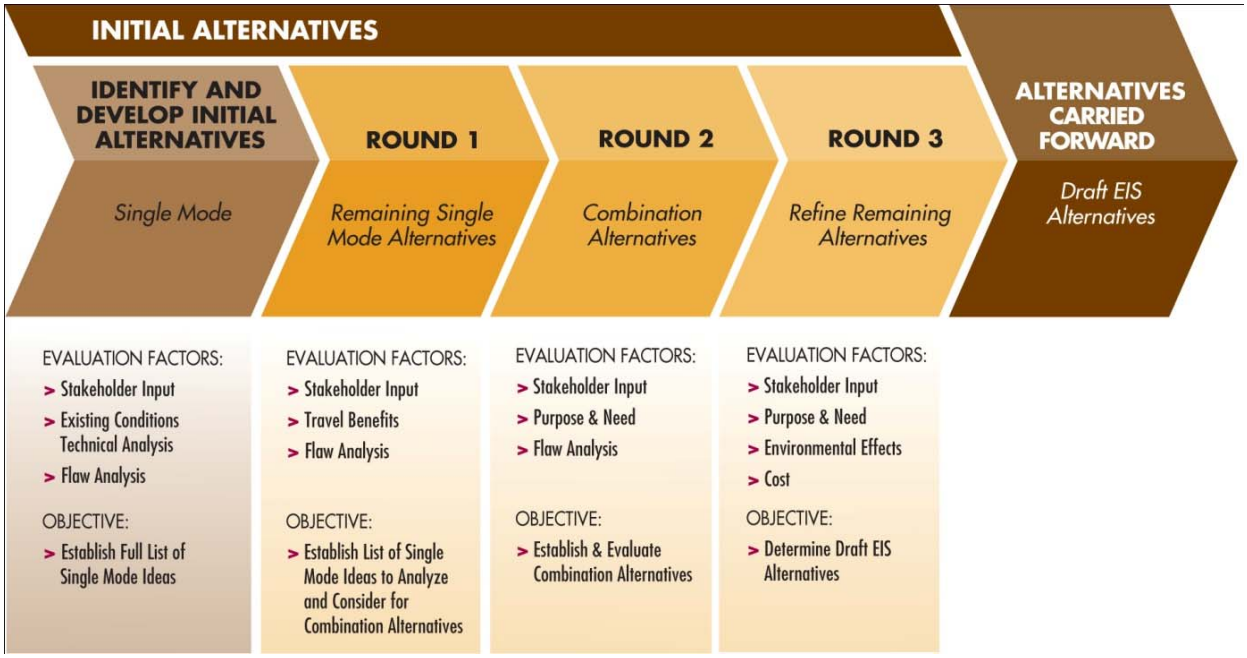
1.0 Executive Summary

The I-290 Preliminary Engineering and Environmental (Phase I) Study is being undertaken consistent with the National Environmental Policy Act (NEPA) and federal and state policy to prepare an Environmental Impact Statement (EIS) for multimodal transportation improvements from west of Mannheim Road to Racine Avenue (see Figure 1-1).

Figure 1-1. Study Area Map

The NEPA process guides potential federal actions to consider impacts to the environment, and requires the evaluation of alternative ways of accomplishing study goals and meeting study needs (Figure 1-2). The NEPA process establishes three primary steps in project development for an EIS: Establish the Purpose and Need, Alternatives Development and Evaluation, and Identification of the Preferred Alternative.

Figure 1-2. Environmental Impact Statement Planning Process



This document, which will be updated as the planning process advances, describes the alternative development and evaluation process used. This process, as illustrated in Figure 1-3, will include:

- Round 1 - The identification and evaluation of single mode alternatives, which are alternatives that consider changes to or improvements of only one mode of transportation, to understand the effectiveness and characteristics of each individual mode.
- Round 2 - The evaluation of an initial set of combination mode alternatives assembled based on the findings from the Round 1 single mode evaluation. Combination mode alternatives include improvements to or additions of more than one mode of transportation (e.g. transit and expressway improvements).
- Round 3 - The revision of the combination alternatives based on the initial results and further development and evaluation.

The goal of this process is to identify the alternatives to be carried forward for evaluation in the Draft EIS. The process also provides the opportunity to examine all modes of travel within the transportation system, which can provide the basis for future planning efforts by other area transportation agencies (i.e. RTA, CTA, Pace, etc).

Figure 1-3. Initial Alternatives Development and Evaluation Process

Prior to the initial alternatives identification process, the Illinois Department of Transportation (IDOT) initiated a project context audit to identify key features of the project area, characteristics of key transportation facilities, and conditions that should be addressed in the scope of the study. With this information, IDOT and the Corridor Advisory Group (CAG)/Task Forces (TF), prepared a project problem statement (February 2010). With stakeholder and transportation agency input, the study team evaluated the condition and performance of the existing transportation system. This activity focused on the identification of transportation needs of the study area, and was documented in the Existing Transportation Systems Performance (ETSP) Report, August 2010. Based on the findings from the ETSP and with stakeholder input, the Purpose and Need for the project was developed between July 2010 and

December 2011 beginning with a basic outline that was gradually expanded and discussed with the CAG/TF and other stakeholders over the course of five CAG/TF meetings and a public meeting in May of 2011. The five needs identified for the I-290 Study Area are:

1. Improve regional and local travel
2. Improve access to employment
3. Improve safety for all users
4. Improve modal connections and opportunities
5. Improve facility deficiencies

A regional travel demand model was used as the evaluation tool for testing the transportation performance of alternatives. To evaluate alternatives, the project established a baseline or "No Build" based on the Chicago Metropolitan Agency for Planning (CMAP) 2040 fiscally constrained network data to forecast future travel conditions outside the study area, and assuming no improvements to I-290 in the study area. As the accepted plan for the regional transportation system for the year 2040, this model establishes the project's No Build alternative, which is 'alternative neutral' and is the baseline condition against which the transportation performance of alternatives area evaluated. Appendix H describes the travel forecasting assumptions. The evaluation process includes a relative comparison between alternatives and comparison of each alternative to the No Build alternative. Specific population and employment forecasts will be developed for the evaluation of the alternatives in the Draft EIS.

Alternatives were initially evaluated for fatal flaws throughout the process. A fatal flaw is defined as a characteristic or component of an alternative that would render it infeasible or impractical in the context of this study. Flaws could include substantial direct impacts to residences, businesses, environmental resources, or community facilities. A fatal flaw could also result from the improvement being beyond the context of the I-290 Phase I Study Area or needs. Alternatives that have costs that are not reasonable and prudent can also be removed from consideration.

1.1 Initial Alternatives Identification Summary

The initial alternatives for the Round 1 evaluation were identified through a pre-screening process that considered approximately 460 alternative suggestions submitted by project stakeholders on how to address the Purpose and Need of the I-290 project. These suggestions were sorted into three main groups: roadway improvements, transit improvements, and related improvements that could be combined with other concepts. Each of the three groups was subdivided into concept categories based on the stakeholder suggestions provided (example: add general purpose lanes to I-290). As discussed further in Section 4 and Appendix A of this document, 33 concept categories emerged to which each suggestion was assigned.

The 33 concept categories were pre-screened by IDOT to identify which concepts would be either carried forward into Round 1, not carried forward, or deferred for future evaluation. The pre-screening resulted in 11 of the 33 original categories carried forward into the Round 1 evaluation. In addition to these single mode alternatives, 11 other categories of related improvements were deferred for future consideration.

1.2 Round 1 (Single Mode Evaluation) Summary

The purpose of the single mode evaluation was to understand the effectiveness and characteristics of each individual mode. A regional travel demand model was used to test the alternatives, and is based upon decades of research and calibration to appropriately portray existing and expected future conditions; the CMAP GO TO 2040 plan was used as a base for forecasting future conditions. The model seeks the most efficient mode of travel based upon travel costs and times, trip purposes, and the time-of-day for the trip.

Twenty-one single mode alternative concepts, that are derivative of the 11 single mode concept categories carried forward from the pre-screening, were developed by the study team and CAG/TF for evaluation in Round 1. The 21 single mode alternatives are summarized in Table 1-1, and a set of maps representing these alternatives is provided in Appendix C. Some of the concept categories resulted in multiple single mode alternatives. For example, three versions of the CTA Blue Line extension concept were carried forward as single mode alternatives with different project termini.

Table 1-1. List of Single Mode Alternatives Evaluated in Round 1

Transit Mode Alternatives (9 total)

Blue Line Extension (Heavy Rail Transit - HRT) 	[HRT 1] From Forest Park To Oak Brook via IL Prairie Path and Butterfield Road
	[HRT 2] From Forest Park To Oak Brook via IL I-290 and I-88
	[HRT 3] From Forest Park To Mannheim via I-290
Express Bus 	[EXP] Various service from DuPage and Northwest Cook Counties to Forest Park CTA terminal
Bus Rapid Transit (BRT) 	[BRT 1] Oak Brook to Forest Park - via Butterfield Road and IL Prairie Path
	[BRT 2] Oak Brook to Forest Park - via I-88 and I-290
	[BRT 3] Oak Brook to Cicero Avenue - via I-88 and I-290
	[BRT 4] Oak Brook to Ashland Ave - via I-88 and I-290 – CTA Blue Line conversion
	[BRT 5] Lombard to Forest Park - via I-88 and I-290

Expressway Mode Alternatives (11 total)

General Purpose (GP) Add Lane			[GP LANE] General Purpose Add Lane from I-88 to Central Avenue
Managed Lanes	**High Occupancy Vehicle (HOV) Lanes**	**2+ Riders** 	[HOV 2LL] Oak Brook to Racine Avenue
			[HOV 2L] I-88 to Racine Avenue
			[HOV 2W] Oak Brook to Central Avenue
		3+ Riders 	[HOV 3LL] Oak Brook to Racine Avenue
			[HOV 3L] I-88 to Racine Avenue
			[HOV 3W] Oak Brook to Central Avenue
	High Occupancy Toll (HOT) Lanes		[HOT 1] Oak Brook to Central Avenue, 3+ Vehicles Free
			[HOT 2] Oak Brook to Racine, 3+ Vehicles Free
	Toll Lanes		[TOLL 1] Toll Existing I-290 Lanes, I-88 to Cicero Avenue
			[TOLL 2] Toll I-290 with Add Lanes , I-88 to Cicero Avenue

Arterial Mode Alternatives (1 alternative with two variations)

Arterial Widening	With Parking	[ART 1 & 2] Widening of Roosevelt Road and Madison Avenue to 4 continuous lanes (2 lanes each direction). • Roosevelt Road from I-294 to Cicero Avenue • Madison Avenue from 25th Avenue to Cicero Avenue
	Without Parking	

The Round 1 single mode travel benefit evaluation results were presented to, and reviewed by the CAG/TF, in July 2011 and September 2011. Further discussion on the single mode evaluation results continued at subsequent CAG/TF meetings. Based on the Round 1 evaluation findings and stakeholder and transportation agency input, an initial set of combination mode alternatives were identified for evaluation in Round 2 in September 2011, and were further refined at the December 2011 CAG/TF Combination Alternatives Workshop.

The following is a summary of the single mode evaluation results:

Transit Modes

The Blue Line extension and BRT single mode alternatives were the best performing transit alternatives with similar results and the express bus alternative resulted in local travel and job accessibility improvements. However, no single mode transit alternative showed improvement to I-290 travel performance due to the already well-established and utilized study area transit network, with new service drawing insufficient auto-trip diversions to offset auto demand for I-290, and a smaller narrower transit market as compared to I-290. Given the extent of the existing transit market in the study area, ridership gains on new transit services are limited, and any ridership on new transit services would be comprised primarily from riders diverting from existing service. For example, the Blue Line extension to Oak Brook alternative [HRT 2] attracts

24,550 riders, 13,260 (54 percent) of these riders are diverted from existing transit services (PACE, Metra), and 8,350 (34 percent) are diversions from auto.

Highway Modes

The single mode expressway alternatives resulted in the highest travel performance improvements to the I-290 Expressway, as well as the best improvement of regional and local (study area) travel performance. This is due to improving travel for the large market served by I-290, for both the traditional and reverse commute patterns. Managed lane expressway alternatives (HOV and HOT) provide some of the best performance benefits because they add capacity to address the underserved demand in this corridor, and manage its use effectively. The expressway alternative that did not add capacity to I-290 resulted in poorer performance with I-290 traffic diverted to study area arterials.

Arterial Widening

An initial fatal flaw footprint impact evaluation found that arterial widening for Roosevelt Road (IL 38) from I-294 to Cicero Avenue and Madison Avenue from 25th Avenue to Cicero Avenue (with and without parking) resulted in a large number of displacements and, therefore, arterial widening was determined to be fatally flawed and not carried forward for performance evaluations. Arterial improvements will be further considered in conjunction with other modes as the evaluation process advances.

Overall

While single mode transit alternatives offer some travel benefits, they do not show any improvement to I-290 performance. Overall, expressway modes provide the best travel improvements locally and regionally. Combinations of transit and expressway alternatives will be assembled and evaluated to identify any transportation performance synergies to be gained by various combinations.

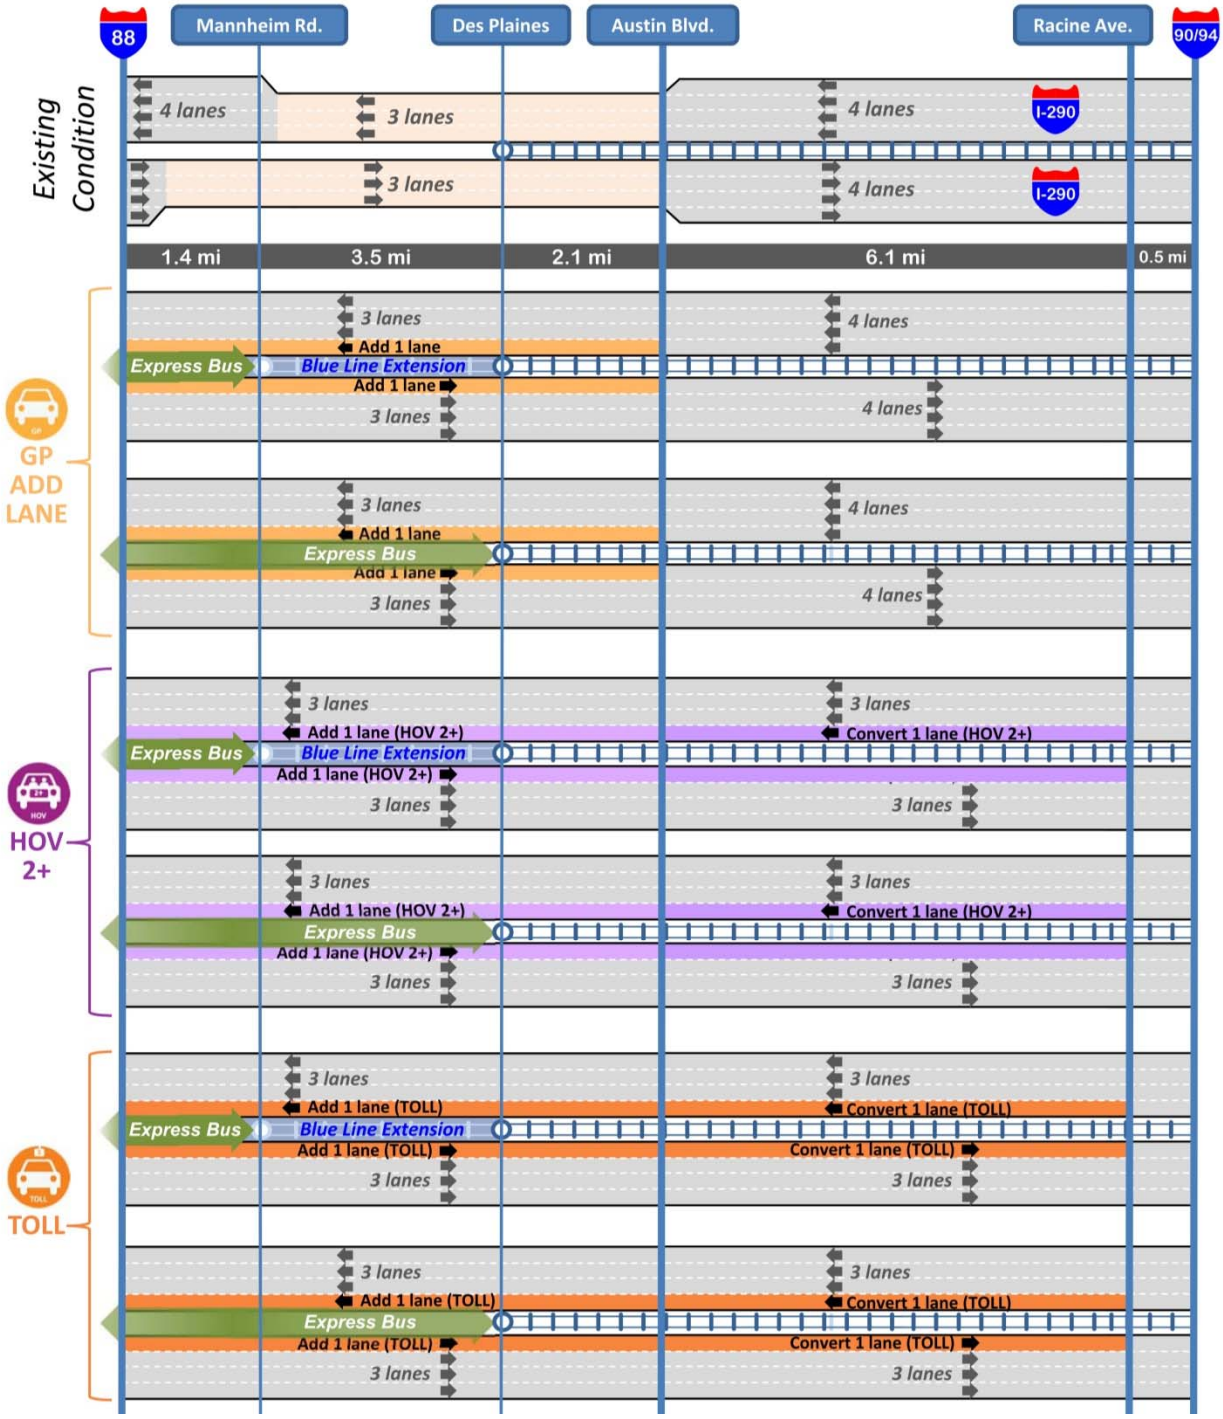
The following single modes were dropped from further consideration as part of the I-290 Study, for the following reasons:

- Blue Line Conversion to Bus Rapid Transit (BRT 4): The BRT 4 Alternative from Oak Brook to Ashland Avenue was evaluated as a conversion of the existing CTA Blue Line to a Bus Rapid Transit facility between Ashland Avenue and the Forest Park terminal. This alternative indicated generally similar and some improved performance as compared to an HRT Blue Line extension to Oak Brook (HRT 2), however, due to the similarity in performance and ROW requirements for these two fixed guideway transit facilities, the HRT extension of the Blue Line will be the representative mode that will be modeled and evaluated in the combination alternatives.
- *Blue Line Extension and BRT Alternatives along the Prairie Path (HRT 1 and BRT 1):* The Blue Line extension and BRT alternatives along the Prairie Path and along I-290 (HRT 2) perform very similarly. However the Prairie Path alignment has greater service overlap/duplication with the existing Metra service, diverting more riders from the UP-West line than the alignment along I-290. There are also potential conflicts with the recreational functions of the Illinois Prairie Path corridor and Section 4(f) of the US Department of Transportation Act of 1966. Therefore, the alternatives using the Prairie Path alignment are not being carried forward for evaluation in Round 2.

Identification of Initial Combination Modes

The results from the single mode evaluation were used to establish the set of combination mode alternatives for evaluation in Round 2. Each of the five Expressway & Express Bus alternatives are also paired with an HCT extension from the Forest Park CTA terminal to Mannheim Road. Figure 1-4 summarizes the 12 combination mode alternatives, and map exhibits that fully describe each of the 12 combination mode alternatives are provided in Appendix F.

Figure 1-4. 12 Combination Mode Alternatives



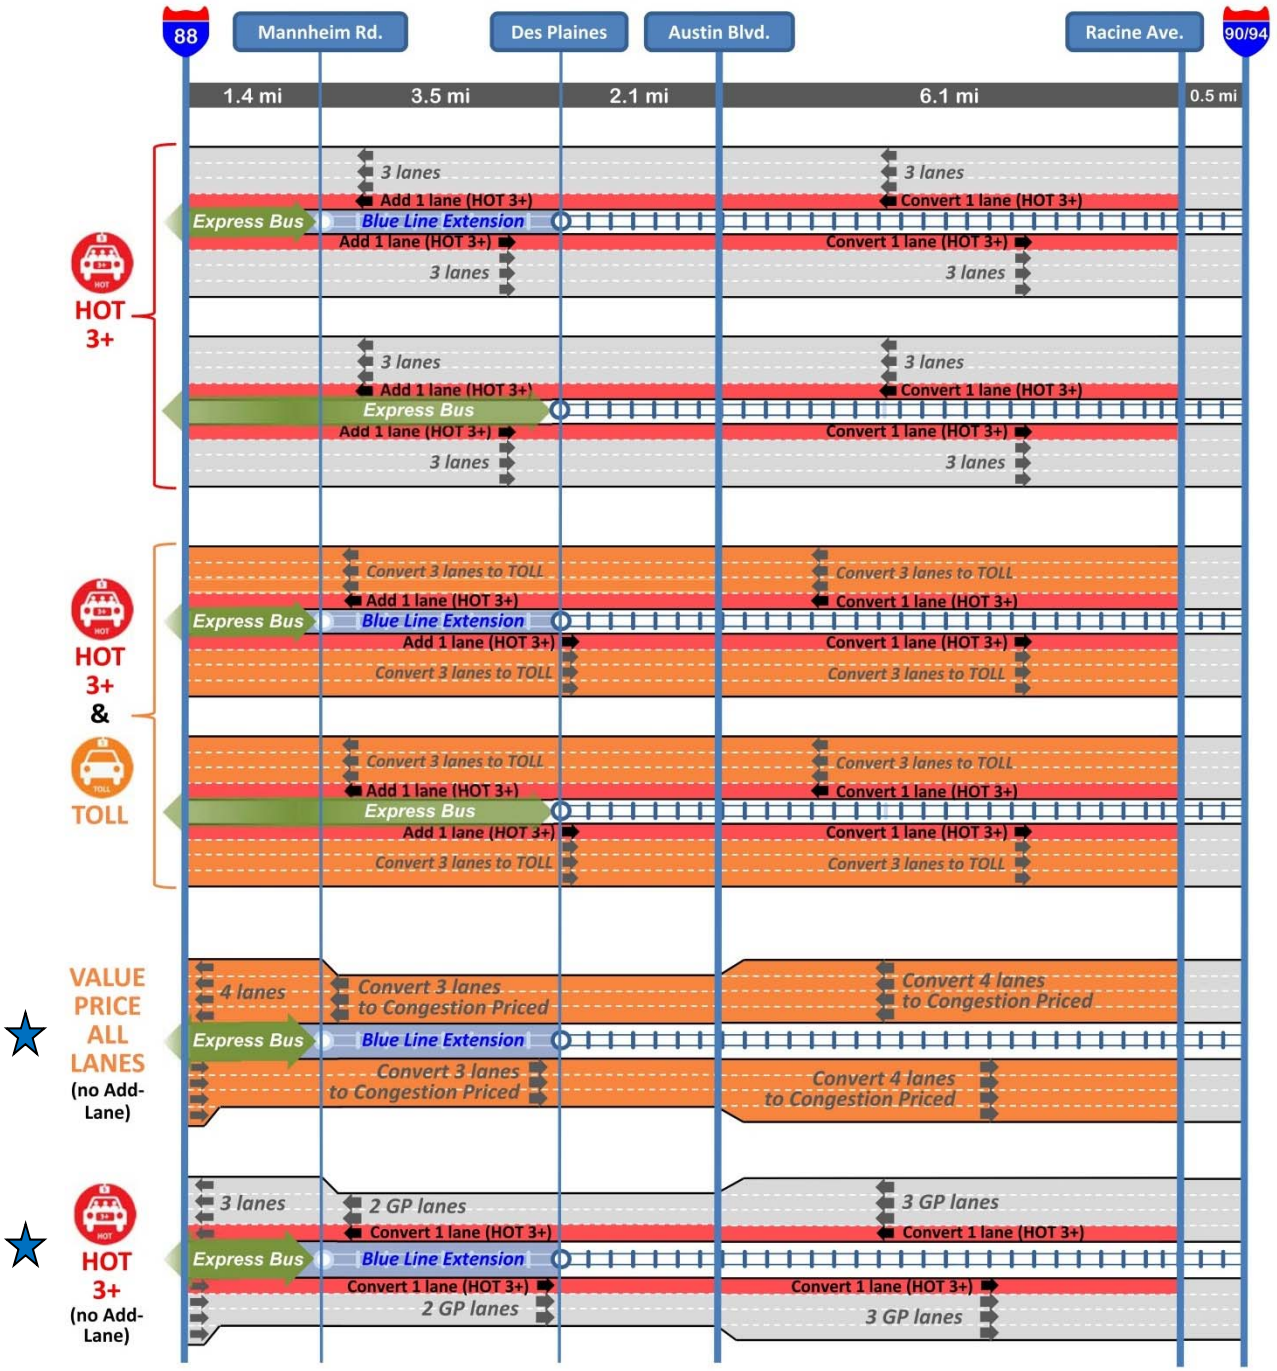


Figure 1-5. 12 Combination Mode Alternatives (continued)

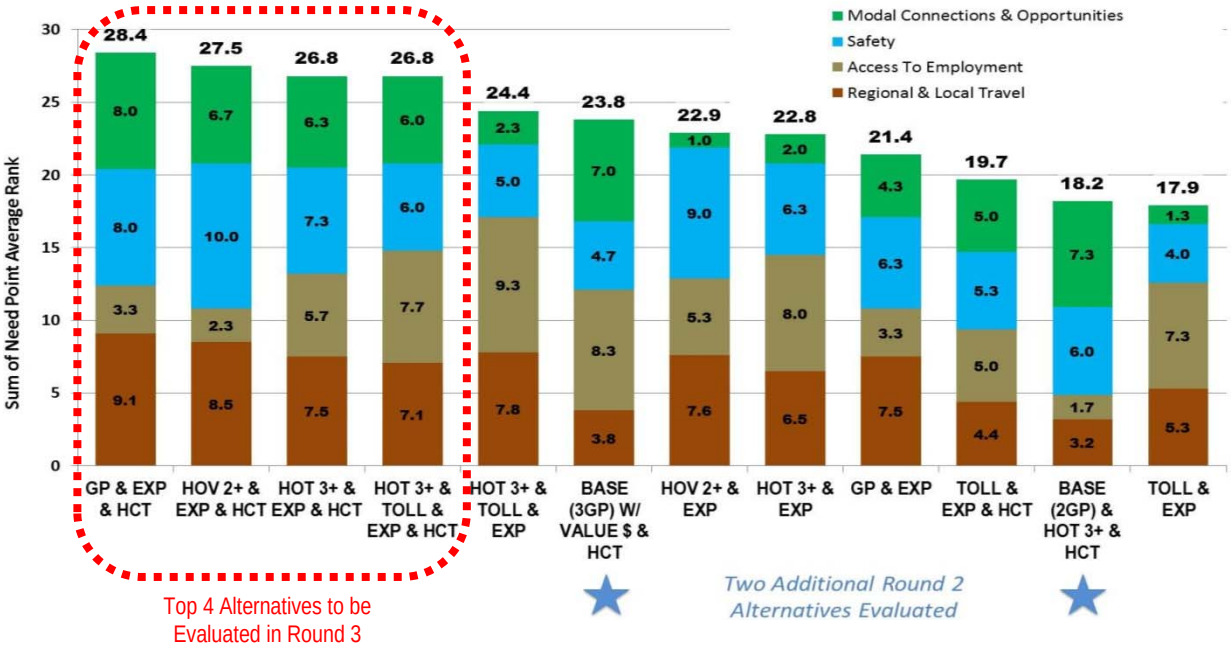
★ Additional Round 2 Initial Combination Mode Alternatives considered, January 2013

1.3 Round 2 - Initial Combination Mode Evaluation Summary

In Round 2, twelve combination mode alternatives were evaluated to determine the collective results of combining various single mode alternatives. This included the ten combination mode alternatives identified at the end of Round 1, plus an additional two alternatives that were suggested by the Corridor Advisory Group. A full discussion of the Round 2 evaluation is provided in Section 6.0 of this report.

As in Round 1, Round 2 evaluated four of the five need points:



1. Improve Regional and Local Travel
2. Improve Access to Employment
3. Improve Safety for All Users
4. Improve Modal Connections and Opportunities

The fifth need point, Improve Facility Deficiencies, was not evaluated due to a lack of sufficient detail at this stage in the study.

The Round 1 evaluation measures were carried forward into Round 2 but with some revisions based on stakeholder input. Four measures for Improve Regional and Local Travel were removed due to similarity or overlap with other measures, and two additional measures were added for the evaluation of the Improve Modal Connections and Opportunities need point. The alternatives scoring methodology was also revised in Round 2 to give each need point equal weight in the overall score of an alternative. The evaluation measures are presented in Section 3.0, and the Round 2 revisions to the measures and scoring are further explained in Section 3.0.

The overall results of the Round 2 evaluation of the initial combination mode alternatives are presented in Figure 1-6 below. The total scores for each alternative in this figure is the cumulative result of the individual need point scores. The evaluation of each need point is discussed in Section 6 of this report. The individual results or each measure and need point are summarized in the Evaluation Matrix provided in Appendix G.

Figure 1-6. Round 2 Overall Alternatives Scoring Summary

As seen in Figure 1-6, the scores range from a high of 28.4 to a low of 17.9, with the largest gap in scores between the top four and the remaining eight alternatives. The GP & EXP & HCT alternative had the highest overall score of all combination alternatives, followed by the HOV 2+ & EXP & HCT, HOT 3+ & EXP & HCT, and the HOT 3+ & TOLL & EXP & HCT alternative. The following summary describes the general effects of adding general purpose or managed lanes to I-290, not adding lanes to I-290, converting existing general purpose lanes to managed lanes, tolling, and transit improvements. It is important to note that the travel demand modeling process is dynamic; travel is being assessed and recalculated over the entire six county region for each alternative. Depending upon the type of improvements and combination of improvements, the number of trips in the study area may change, trips may shift from one mode to another (i.e., highway to transit), trips may take differing paths, and trip lengths may change. Therefore, each combination alternative yields differing performance results.

General Observations

Adding a Lane to I-290:

- The top four scoring alternatives include both an additional lane on I-290 between Mannheim Road and Austin Boulevard, and an extension of the CTA Blue Line to Mannheim Road ("HCT") with supporting express and feeder bus services.

  – Adding a lane generally results in improved travel times (decrease in Vehicle Hours Traveled, "VHT") on I-290 as well as the arterial system.
  – Adding a lane on I-290 generally results in an increase in expressway travel (Vehicle Miles Traveled, "VMT") and a decrease in arterial travel (VMT).
  – Adding a *general purpose* lane attracts the most *traffic* onto I-290, while adding a *managed lane*, with higher vehicle occupancy rates and/or pricing, allows more *people* to travel through the corridor ("daily person throughput").

- Travel time savings provided by a tolled managed lane makes the I-290 corridor relatively more attractive for longer distance trips, and consequently, longer distance trips shift onto I-290, and VMT is increased. However, there is a corresponding decrease in VHT due to the additional capacity provided.
- Tolling, even with adding a lane on I-290, generally results in relatively lower performance on the arterial system. Tolling makes I-290 slightly less attractive for shorter trips that would otherwise divert from the arterial system to I-290.
- Managed lanes shift some trips away from transit because of the added capacity and I-290 travel time improvements.
- Managed lanes result in net improvement in travel times in the remaining general purpose lanes. Existing (and future) carpoolers are drawn to the managed lane and away from the remaining general purpose lanes.

Not Adding a Lane to I-290:

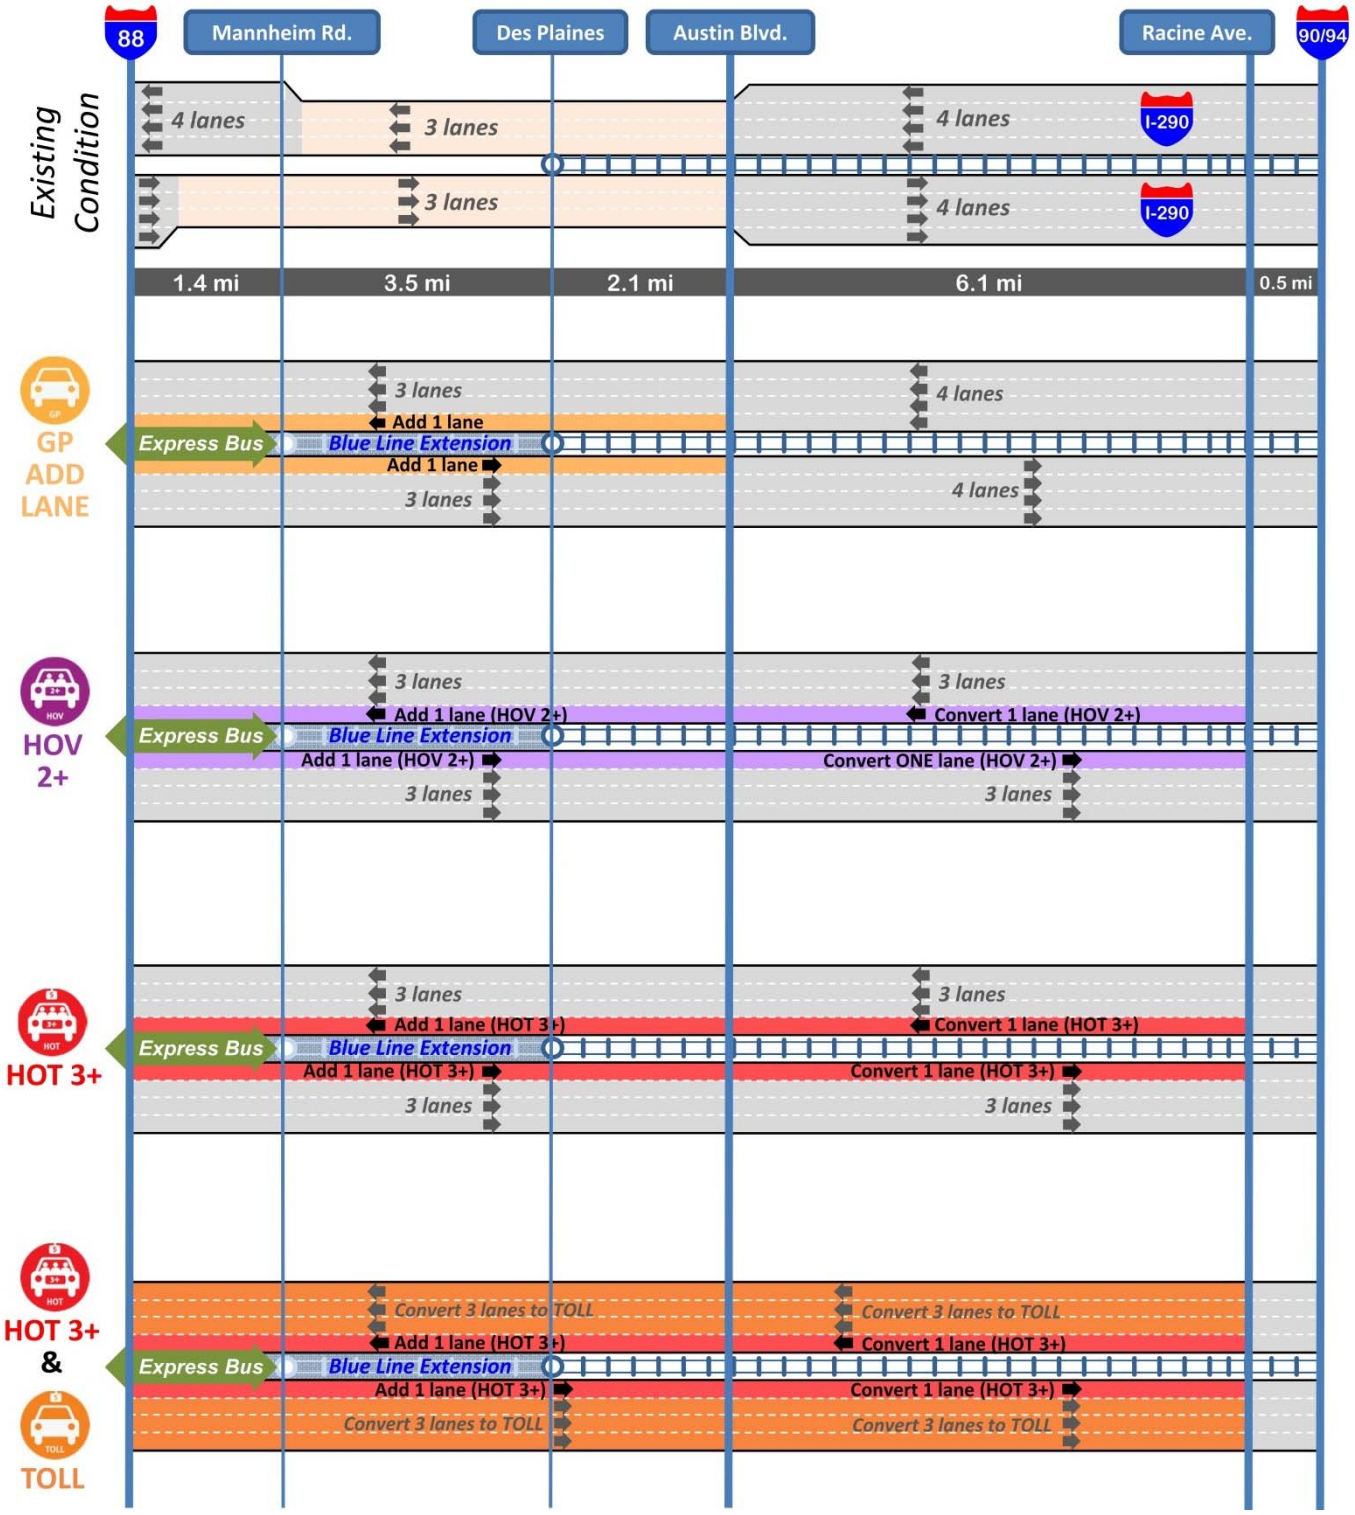
- The alternatives that did not include an additional lane on I-290, even in combination with a HCT and supporting bus services, performed relatively poorly.

  - The lack of an additional lane, coupled with congestion pricing or existing lane conversions that restrict flow on I-290, causes a significant shift of travel to an already congested arterial system.
  - Value (congestion) pricing shifts longer distance trips onto I-290 (increased VMT), but congestion pricing, without adding lanes to I-290, also has a net negative effect upon regional and arterial VHT due to the added capacity constraints imposed on the overall system.

Transit Service Expansion

- The alternatives that included HCT and supporting bus services created the relatively **highest number of new transit trips**, but over 50% of the total ridership consists of trips diverted from other existing transit services.
- The alternatives that included HCT and supporting bus services provide **new high capacity options for the reverse commute**.
- The alternatives that included HCT and supporting bus services **generally resulted in increased VMT**, as compared to alternatives without these transit components. This is because the HCT improvements in the study area shift some medium and shorter distance trips from auto and on to transit. This frees up capacity for longer distance trips to shift on to I-290.
- The alternatives that include HCT and supporting bus services provided **slightly better safety performance** as compared to alternatives that did not include HCT, due to the shift in trips to transit (and to I-290), which has a higher safety performance.

Overall/Combined Performance – Top Four Alternatives



As noted above, the top four alternatives scored relatively higher than the other eight alternatives that were considered in round 2. The following is a description of the combined performance, including all four need points, for each of the top four alternatives.

- The GP & HCT alternative provides the best overall score of 28.4, driven by having the highest regional and local travel and modal connections and opportunity improvements, as well as providing good safety performance. The added capacity attracts longer distance trips from the arterial network and onto the expressways for which they are intended. This shift from arterials also improves arterial performance in the study area, giving GP lanes the relatively highest overall performance for improving regional and local travel. The GP lane combination alternatives showed a lower accessibility to jobs and safety performance compared to other alternatives. Accessibility to jobs for the GP Lane combination alternatives is improved over the baseline condition, but not to the same extent as the managed lane alternatives. This is due to the managed lanes providing a faster path than the GP Lanes, allowing users of the managed lanes to access more jobs located further away in 60 minutes or less. With respect to safety, GP Lane combination mode alternatives provide more vehicle throughput than the managed lane combination mode alternatives. This increased throughput slightly increases the potential for crashes relative to the managed lane combination mode alternatives.
- The HOV 2+ & HCT alternative scored second best overall at 27.5, and provided the best safety performance, and the second highest improvements to local and regional travel, as well as ranking as one of the top three for modal connections and opportunities. HOV lanes provided as much as a 40% reduction in daily hours of congestion in the managed lane, and over 11% in the general purpose lanes. This is due in part to the already high percentage of HOV 2+ vehicles in this corridor that could use the HOV 2+ lane. The HOV 2+ combination alternatives indicated the highest safety performance improvements due to the combination of increased expressway traffic volume and increased person throughput.
- The two HOT 3+ combination mode alternatives (with and without TOLL) showed good overall performance with two HOT 3+ combination mode alternatives in the top 4 overall performers. The two HOT 3+ alternatives in the top four both scored the same overall, with a need point rank sum of 26.8. The two HOT 3+ alternatives, reflected the highest performance related to access to employment due to HOT 3+ use restrictions that better manage operations that results in a relatively faster route (as compared to other combination alternatives) to jobs from the study area. The HOT 3+ & TOLL induces further reduction in demand along I-290, resulting in additional travel time savings that translate into more jobs accessible in 60 minutes. Safety performance in these alternatives was generally better compared to other combination alternatives due to relatively lower traffic volumes (less risk of crashes) and higher person throughput. It should be noted that conversion of existing non-tolled GP interstate lanes to HOT or Toll lanes is currently restricted legislatively, although there are federal programs that allow conversion of HOV lanes to HOT lanes, and the conversion of GP lanes to value pricing.

Identification of Combination Modes for Evaluation in Round 3

The results from the Round 2 combination mode evaluation establish the set of alternatives for further evaluation in Round 3. As noted above, the top four alternatives overall scores were relatively higher than the remaining eight alternatives, and as such, the top four alternatives, shown in Figure 1-7, will be carried into Round 3 for further evaluation. The proposed Round 3 alternatives will be refined to improve their performance with respect to each need point, with access to employment being a particular focus. Additional engineering detail will be added to these alternatives, which will allow for an expansion of the evaluation criteria, including social, economic, environmental and cost factors. As shown in Figure 1-7, the following four alternatives are being advanced into Round 3:, GP & EXP & HCT, HOV 2+ & EXP & HCT, HOT 3+ & EXP & HCT, and HOT 3+ & TOLL & EXP & HCT.

Figure 1-7. Four Alternatives to be Evaluated in Round 3

2.0 Alternatives Identification and Evaluation Process

After the project needs were identified, alternatives were formally sought to address those needs. The process for developing alternatives and evaluating those alternatives consisted of four iterative steps, which are described below:

1. Identify and Develop Initial Alternatives
2. Round 1 – Single mode evaluation
3. Round 2 – Initial combination mode evaluation
4. Round 3 – Identification of Draft EIS alternatives

These four steps will be used to screen a large range of concepts resulting in the alternatives to be carried forward into the Draft EIS for detailed development and evaluation. Alternatives will be evaluated relative to each other and to the baseline or No Build Alternative. A range of factors were considered in the evaluation process, including: transportation performance, stakeholder input, logical termini, fatal flaws, impacts, and cost.

The goal of this process is to identify the alternatives to be carried forward for evaluation in the Draft EIS. The process also provides the opportunity to examine all modes of travel within the transportation system, which can provide the basis for future planning efforts by other area transportation agencies (i.e. RTA, CTA, Pace, etc). The CTA is conducting a concurrent Blue Line Forest Park Branch Feasibility/Vision Study that will assess current conditions and identify modernization needs for rail infrastructure and customer amenities for both the near and long term.

A regional travel demand model was used as the evaluation tool for testing the transportation performance of alternatives in Rounds 1, 2, and 3. The travel demand model is based upon decades of research and calibration to appropriately portray existing and expected future conditions. To evaluate alternatives, the project established a baseline or "No Build" based on Chicago Metropolitan Agency for Planning (CMAP) 2040 fiscally constrained network data to forecast future travel conditions outside the study area, and assuming no improvements to I-290 in the study area. As the accepted plan for the regional transportation system for the year 2040, this model establishes the project's No Build alternative, which is 'alternative neutral' and is the baseline condition against which the transportation performance of alternatives are evaluated. Appendix H describes the travel forecasting assumptions. The evaluation process includes a relative comparison between alternatives and comparison of each alternative to the No Build alternative. Specific population and employment forecasts will be developed for the evaluation of the alternatives in the DEIS.

2.1 Initial Alternatives Identification

Alternatives suggestions for the I-290 Study were solicited from project stakeholders and the public through public meetings, CAG/TF meetings, via comments submitted to the project website or by other means. Initially, single mode alternatives were sought for evaluation; single mode alternatives are those that involve one mode of transportation (commuter rail, bus rapid transit, subway, HOV lanes, etc.) for the modification of, or addition to, the study area. The purpose of evaluating the single modes was to understand the effectiveness and characteristics of each individual mode. The submitted alternatives were categorized, reviewed, and screened to identify an initial set of 'corridor level' single mode alternative concept categories that fit within the context of the study for initial evaluation in Round 1. 'Corridor level' alternatives are those alternatives that include the general location, configuration, and mode type of a potential solution. This list was developed, coordinated, and refined with project stakeholder input.

2.2 Round 1 – Single Mode Evaluation

A total of 21 single mode alternatives were identified for evaluation in Round 1, including 9 transit, 11 expressway, and one arterial widening alternative. A summary of the evaluation that led to the selection of these single mode alternatives is provided in Section 4.0.

The initial set of identified 'corridor-level' single mode alternatives were reviewed for possible fatal flaw impacts, and those not identified as fatally flawed were evaluated with the travel demand model to compare relative transportation performance. Using the results of the Round 1 evaluation, and stakeholder and transportation agency input, various single mode expressway and transit alternatives were reviewed for consideration in combination mode alternatives for further evaluation in Round 2. A summary of the Round 1 evaluation, findings, and list of initial combination mode alternatives is provided in Section 5 of this report.

2.3 Round 2 – Combination Mode Evaluation

Using the results of the Round 1 evaluation, and stakeholder and transportation agency input, a set of 12 combination mode alternatives were assembled for evaluation in Round 2. Combination mode alternatives are those that include two or more single modes as part of an overall corridor level alternative. The results of the Round 2 evaluation will be reviewed with the stakeholders and transportation agencies, and those initial combination mode alternatives that perform well and are not fatally flawed will be considered and/or revised for further evaluation in Round 3.

2.4 Round 3 – Refinement of Remaining Alternatives

In Round 3, with additional stakeholder input, the alternatives and features are further refined based on the findings from Round 2 evaluation. Alternative refinements will undergo additional travel modeling and traffic analysis, impact evaluation (geographic information system (GIS) level footprint, environmental and social impacts), and cost considerations.

Interchanges, access, cross-streets, frontage roads, transit access, non-motorized, and other transportation features will also be developed and evaluated.

The objective at the end of Round 3 is to identify the primary modes, alignment(s), and features of the alternative(s) to be carried forward for evaluation in the DEIS.

(NOTE TO READER: This section and Section 7 will be updated at the completion of the Round 3 Evaluation)

3.0 Evaluation Measures

Measures of transportation performance were developed to evaluate the respective benefits of each alternative. The measures which follow represent the initial evaluation list which is expected to be refined as the alternatives screening process proceeds into subsequent rounds of evaluation. This will also account for more detailed level of design, the refinement of the alternative concepts, and the outcomes of those evaluations.

3.1 Footprint/Fatal Flaw Screening – GIS Level Analysis

Screening was initiated to evaluate the physical impacts of an alternative, or footprint, within the study area based on right-of-way requirements. A geographic information system (GIS) level of analysis was used for the initial screening to assess impacts based on information currently available. In addition, a constraint workshop was held with the Corridor Advisory Group to identify potential footprint constraints along I-290. The most detailed environmental and socioeconomic analysis, field studies, and documentation will be completed for the DEIS alternatives. Table 3-1 lists the measures of physical impacts of an alternative to be evaluated in Round 1 and in Round 3:

Table 3-1. Footprint Screening Measures

Footprint Screening	Unit	Round 1	Round 2	Round 3
Additional right-of-way required/footprint	acres	●	-	o
Displacements (direct impact to residences and businesses)	#	●	-	o
Parkland Impacts	acres	●	-	o
Historic Property Impacts	#	●	-	o
● Completed as of this version of the report o Yet to be completed as of this version of the report				

Alternatives that would result in impacts or displacements may be determined to be fatally flawed and dropped from further consideration.

3.2 Performance & Purpose and Need Screening

The following measures were selected in each need category based on their linkage to addressing the needs outlined in the I-290 Draft Purpose and Need Statement. The following presents the measures to be used in Rounds 1, 2, and 3 evaluations. In Round 1, the performance based measures will be used for the single mode evaluation. Further evaluation with respect to the Purpose and Need will be added in Rounds 2 and 3 as the combination mode alternatives are identified and further defined.

3.2.1 Improve Regional and Local Travel

Measures for improving regional travel listed in Table 3-2 are intended to evaluate the relative potential of an alternative to improve travel conditions through the corridor relative to the 2040 Baseline (No Build) Alternative.

Table 3-2. Regional Measures

Improve Regional Travel	Unit	Round 1	Round 2	Round 3
I-290 Volume to Capacity (v/c)	ratio	●	*not used*	*not used*
I-290 Average Speed	mph	●	*not used*	*not used*
I-290 Average Travel Time	minutes	●	●	o
I-290 Hours of Congestion	hours/day	●	●	o
Person Throughput	persons/day	●	●	o
Vehicle Miles of Travel (VMT)	miles/day	●	●	o
Congested Vehicle Miles of Travel (CVMT)	miles/day	●	●	o
Vehicle Hours of Travel (VHT)	hours/day	●	●	o
Vehicle Hours of Delay	hours/day	●	●	o

I-290 Volume to Capacity Ratio (v/c) – Study Area: Congestion along I-290 affects the ability of this facility to serve regional travel; this measure provides an indication of congestion by relating the actual volume of a facility to its theoretical maximum capacity for acceptable operations. This is expressed as a ratio with values greater than 0.85 indicating potential for congestion, and because the maximum capacity is theoretical, values greater than 1 are possible for this measure. The travel demand model will be used to calculate the AM and PM peak period volume to capacity ratios for each alternative. Lower v/c ratios are desired but this ratio is used as a relative comparison, not an absolute measure. This measure was used in Round 1 only, and was removed for subsequent rounds of evaluation in an effort to consolidate similar measures.

I-290 Average Speed – Study Area: Speeds along I-290 in the study area affect the ability of the expressway to serve regional travel. Average travel speeds along I-290 in the study area for the AM and PM peak periods will be calculated by the travel demand model. Faster travel speeds are desired. This measure was used in Round 1 only, and was removed for subsequent rounds of evaluation in an effort to consolidate similar measures.

I-290 Average Travel Time – Study Area: Travel times along I-290 in the study area affect the ability of the expressway to serve regional travel. Average travel times along I-290 from West of Mannheim Road to Cicero Avenue in the study area for the AM and PM peak periods are calculated by the travel demand model. Travel time changes are reported for all lanes and the managed lane. Shorter travel times are desired.

I-290 Hours of Congestion – Study Area: Congestion along I-290 affects the ability of this facility to serve regional travel. This measure will estimate how many hours of congestion are anticipated per day on I-290 in the study area for each alternative. Congestion is defined as a level of service D or worse on the expressway. The CMAP travel model and/or VISSIM will be used to estimate the volumes on the facility throughout the day and the LOS will be calculated using the Highway Capacity Manual (2000/2010[1]). Fewer hours of congestion per day are desired.

Person Throughput – Study Area: The travel demand model for I-290 will be used to calculate the study area person throughput for each alternative at one or more 'screen line' locations in the study area. Screen lines capture person throughput across specific locations along I-290 and the east-west arterials in the study area. Person throughput for both auto and transit will be evaluated. Higher overall person throughput is desired.

Vehicle Miles of Travel (VMT) – Regional system and Study Area: This measure indicates the distance travelled (in miles) by all the vehicles at the regional and study area levels. The regional travel demand model will be used to calculate this measure.

Congested Vehicle Miles of Travel (CVMT) – Regional system and Study Area: This measure indicates the vehicle miles traveled in congestion per day, and is calculated and compared at the regional and study area levels for each alternative. The regional travel demand model will be used to calculate this measure. Fewer miles traveled in congestion are desired.

Vehicle Hours of Travel (VHT) – Regional system and Study Area: This measure indicates how many hours are traveled each day by vehicles in the region and study area. The travel demand model for I-290 will be used to calculate this measure for each alternative. Fewer vehicle hours of travel are desired.

Vehicle Hours of Delay – Regional system and Study Area: This measure indicates how many hours of delay vehicular traffic is experiencing in the region and study area each day. The regional travel demand model will be used to calculate this measure for each alternative. Fewer hours of delay are desired.

[1] Based on the availability of the current accepted version at the time of evaluation.

Commercial Truck needs have regional importance in this corridor because of the lost time and economic loss due to inefficient truck movements resulting from congestion. This measure differs from the I-290 based measures on Table 3-2 because it evaluates the impacts of an alternative on commercial truck movements which are prominent in this corridor. Regional measures related to truck movements will be evaluated for each alternative. The measures shown in Table 3-3 are the same as the measures above, but limited to trucks.

Table 3-3. Regional Measures - Truck Travel

Improve Regional Travel	Unit	Round 1	Round 2	Round 3
Truck Miles of Travel (TMT)	miles/day	●	●	o
Truck Hours of Travel (THT)	hours/day	●	●	o
Congested TMT	miles/day	●	●	o
Truck Hours of Delay	hours/day	●	●	o

Measures for improving local travel are intended to evaluate the relative potential of an alternative to improve local study area travel conditions. The local travel measures related to the performance of the local arterial network in the I-290 study area are shown in Table 3-4.

Table 3-4. Local Travel Measures

Improve Local Travel – Study Area	Unit	Round 1	Round 2	Round 3
Arterial Volume to Capacity (v/c)	Ratio	●	*not used*	*not used*
Arterial Speeds	Mph	●	●	o
Arterial VMT	miles/day	●	●	o
Arterial Vehicle Hours of Delay	hours/day	●	●	o
Arterial Congested VMT	miles/day	●	●	o
Interchange Level of Service (LOS)	LOS	-	-	o

Arterial volume to capacity (v/c), speeds, vehicle miles traveled (VMT), and vehicle hours of delay are the same measures used regionally, but are evaluated on the study area arterials only. The study area arterials include the north-south streets of Mannheim Road, 1st Avenue, Harlem Avenue, Cicero Avenue, bounded by North Avenue and Cermak Road. The east-west study area arterials are Cermak Road, Roosevelt Road, Madison Street, Lake Street, and North Avenue, bounded by Wolf Road and Cicero Avenue. Arterial volume to capacity was only used in Round 1 and was removed from evaluation in subsequent rounds because other measures from the travel model provide more easily understood arterial performance characteristics.

When appropriate, interchange levels of service (LOS) will also be evaluated; interchanges will be evaluated in Round 3.

3.2.2 Improve Access to Employment

Measures for improving access to employment are intended to evaluate the relative potential of a corridor alternative to improve the accessibility to jobs by number of regional jobs accessible from the study area within 60 minutes. For Round 1, the number of jobs from a single location in the study area was estimated and used to make relative comparisons. In subsequent rounds, the number of jobs accessible from all study area zones are considered. Sixty (60) minutes is used as it able to cast a wider net for jobs accessible by the transit system in the Chicago area. This information is extracted from the regional transportation model based on 2040 baseline population and employment for each alternative modeled as shown in Table 3-5.

Table 3-5. Access to Employment Measures

Improve Access to Employment	Unit	Round 1	Round 2	Round 3
Accessibility to Jobs by Auto	# of jobs/time	●	●	
Accessibility to Jobs by Transit	# of jobs/time	●	●	
Total Accessibility to Jobs (Transit + Auto)	# of jobs/time	●	●	

3.2.3 Improve Safety for All Users

The measure for addressing pedestrian-vehicle conflicts in the each of the evaluation rounds is shown in Table 3-6.

Table 3-6. Safety Measures - Pedestrian-Vehicular Safety

Address Pedestrian-Vehicle Conflicts	Unit	Round 1	Round 2	Round 3
Number of Conflict/crossing Locations at each Interchange	High/Med/Low	-	-	

Number of Conflict/crossing Locations at each Interchange: This measure is evaluated in Round 3 when initial interchange concepts are further developed and refined. The number of existing and proposed interchange conflict points/crossing locations will be counted and compared against existing conditions.

Measures for addressing the high comparative crash rates and high frequency of crashes on I-290 are shown in Table 3-7 and are intended to evaluate the relative potential for an alternative to improve overall safety along I-290 and in the study area.

Table 3-7. Safety Measures - Crash Rates

Address High Comparative Crash Rates and High Frequency of Crashes on I-290	Unit	Round 1	Round 2	Round 3
Arterial Safety – Study Area	injury and fatal (K) crashes per million vehicle miles traveled per year (MVMY)	●	●	
I-290 Safety – Study Area	injury and fatal (K) crashes per million vehicle miles traveled per year (MVMY)	●	●	
Overall Transportation System Safety – Study Area	injury and fatal (K) crashes per million person miles traveled per year (MPMY)	●	●	

Arterial Safety – Study Area: This measure was evaluated for the major east-west and north-south arterials within the I-290 Study area using methods established in the American Association of State Highway & Transportation Officials (AASHTO) Highway Safety Manual (HSM), 1st Edition. Existing characteristics of each route were coded, and travel model traffic volumes of each arterial segment were used to calculate injury and fatality rates for each alternative using the HSM method. This measure is expressed in injuries and fatalities per million vehicle miles traveled per year. Lower injury and fatality rates are desired.

I-290 Safety – Study Area: This measure was evaluated in the I-290 Study area for Rounds 1 and 2 using methods described in the Texas Roadway Safety Manual for highways that will be incorporated in a future edition of AASHTO Highway Safety Manual. Geometric characteristics of the existing facility, and assumptions regarding proposed conditions (including shoulder widths, lane widths, number of lanes, etc.) each were coded, and travel model traffic volumes of each expressway segment were then applied to calculate injury and fatality rates for each alternative using the Texas Roadway Safety Manual methods. The measure is expressed in injuries and fatalities per million vehicle miles traveled per year. Lower injury and fatality rates are desired. HSM methodology for safety evaluation of expressways could be used in subsequent rounds, if available.

Overall Transportation System Safety – Study Area: This measure is used to evaluate the overall safety performance of the alternatives and factors in expressway, arterials, and transit safety performance. The unit for this measure is expressed in injuries and fatalities per million person miles traveled. 'Person miles' is used for this measure because it is the common denominator between both individual vehicular and transit-based travel. Person miles traveled for each facility is calculated from the travel demand model. For expressway and arterials, the injury and fatality rates were calculated by dividing the results of the arterial and highway safety evaluations by the total number of annual person miles traveled on each facility. For this evaluation, it was assumed that there were no injuries or fatalities for users of transit, regardless

of mode (bus or train). The rates of all three facilities were then combined to compare the for the overall safety performance of each alternative. Lower injury and fatality rates are desired.

3.2.4 Improve Modal Connections and Opportunities

Measures for improving access to transit, non-motorized connections, and multimodal opportunities are intended to evaluate the relative potential of an alternative's ability to provide better connections between travel modes, as shown in Table 3-8. Since the last two evaluation metrics listed in Table 3-8 were assumed to be satisfied for all single mode and initial combination mode alternatives, they were not used for evaluation in Round 1 or Round 2.

Table 3-8. Modal Connections Measures

Improve Modal Connections and Opportunities		Unit	Round 1	Round 2	Round 3
New Transit Trips – Region		#	●		
Improve Transit Access – Study Area	Jobs (employment) within ½ mile of transit access	#	-	●	
	Households within ½ mile of transit access	#	-	●	
Improve Non-Motorized Connections – Study Area (qualitative)		✓	-	-	
Improve Multi-Modal opportunities – Study Area (qualitative)		✓	-	-	

New Transit Trips – Region: This measure is used as an indicator of an alternative's ability to improve access to transit. New transit trips are defined as the number of regional transit trips generated by an alternative that exceed the number of regional transit trips of the 2040 no-build scenario. More transit trips are desired.

Transit Access – Study Area: two measures are used to evaluate transit access in the study area. The number of households and jobs (employment) that are within ½ mile of transit access were calculated.

Improving Non-Motorized Connections – Study Area: For this qualitative evaluation, it is assumed that any alternative recommending the reconstruction of existing facilities in the study area will include improvements to non-motorized connections across the I-290 corridor. If an alternative is determined to have the ability to improve non-motorized connections, a ✓ is assigned. This measure will require more definition in future evaluation rounds.

Improving Multi-Modal Opportunities – Study Area: For this qualitative evaluation, it is assumed that any alternative that involves coordination with transit providers and stakeholders regarding transit opportunities has the potential to improve multi-modal connections. If an

alternative is determined to have the ability to improve multi-modal opportunities, a ✓ is assigned. This measure will require more definition in future evaluation rounds.

3.2.5 Improve Facility Deficiencies

Overall, while it is desirous to reconstruct the expressway facility to current design standards, the study area is highly urbanized and contains numerous environmental constraints. As a means to balance good design practice with impact reduction, design will fit in context of its surroundings and the proposed project scope, while also enhancing safety. For the purposes of the initial alternatives evaluation, improve facility deficiencies will not be a differentiator as these types of improvements will be common to all alternatives.

Table 3-9. Facility Deficiencies Measures

Improve Facility Deficiencies	Unit	Round 1	Round 2	Round 3
Pavement Age	yes/no	-	-	-
Structure Deficiencies	yes/no	-	-	-
Geometric Deficiencies	yes/no	-	-	-
ADA ramp and Sidewalk Deficiencies	yes/no	-	-	-
Drainage Deficiencies	yes/no	-	-	-

3.3 Cost Estimates

Conceptual capital cost screening level estimates will be developed based on recent local and or national experience. These cost estimates will typically be based on per mile unit costs and contain an appropriate contingency factor to account for uncertainties in the early screening steps. Cost estimates are considered in Rounds 3 and beyond.

4.0 Initial Alternatives Identification Findings

This section describes the process that was used to identify the alternatives evaluated in Round 1. Section 4.1 presents the range of stakeholder suggestions and Section 4.2 describes the pre-screening process that was used to identify the list of alternatives for the Round 1 screening process.

4.1 Initial Range of Stakeholder Suggestions

Approximately 170 alternatives suggestions were submitted at the first public meeting (November 2009) and at the Corridor Advisory Group/Task Force Alternatives Workshop in December 2010. Over 400 additional comments suggesting alternatives were submitted via the I-290 Study Website, subsequent CAG/TF meetings, and during the comment period for the

second Public Meeting in May 2011. Over 570 suggestions were submitted regarding alternatives. A comprehensive listing of the alternative suggestions is provided in Appendix A.

The suggestions were sorted into three main groups: roadway improvements, transit improvements, and related improvements that could be combined with other concepts. Based on the stakeholder suggestions, each of the three groups was subdivided into 33 distinct concept sub-categories (example: add general purpose lanes to I-290) to which each suggestion or comment was assigned. A functional description of each concept category can be found in Appendix A which includes a table that describes how the 570 alternatives were screened. A summary of the various concepts by mode are provided in map form in Appendix B. Section 4.2 describes the pre-screening results of the 33 concept categories.

4.2 Single Mode Alternatives Concept Screening

The 33 concept categories were pre-screened to identify the single mode alternative concepts to be carried forward for evaluation in Round 1. Each concept was either: (1) carried forward into Round 1, (2) not carried forward into Round 1, or (3) deferred to a later round of evaluation. An important factor in the pre-screening process was the potential to serve the two largest travel markets in the I-290 study area. The two largest travel markets, as identified by the RTA Cook DuPage Corridor Study Travel Market Analysis (December 2005), are the traditional and reverse commute markets, which serve the highest density of work trip origins and destinations concentrated in the city of Chicago, the near west suburbs centered along the I-290 Study area, and in eastern DuPage County to the west. Concepts that had large right-of-way impacts on adjacent communities were not carried forward for further study. Other related improvements were deferred to future screening rounds.

Table 4-1 summarizes the results of the concept category pre-screening process. A functional description and a detailed disposition for each concept category are provided in Appendix A.

Table 4-1. Summary of Pre-Screening Findings

Concept Categories	Concept Disposition		
	Carried Forward	Not Carried Forward	Deferred to subsequent rounds
Roadway Improvements			
Add general purpose lanes to I-290	✓		
Add high-occupancy vehicle (HOV) lanes to I-290	✓		
Add high-occupancy toll (HOT) lanes in each direction	✓		
Toll I-290 lanes	✓		
Arterial Widening	✓		
Transit Improvements			
Extend CTA Blue Line to O'Hare Airport		✓	

Concept Categories	Concept Disposition		
	Carried Forward	Not Carried Forward	Deferred to subsequent rounds
Extend CTA Blue Line west	✓		
Extend CTA Blue Line west via Illinois Prairie Path	✓		
Add CTA Blue Line express service			✓
Extend CTA Green Line to Maywood		✓	
Add BRT via Prairie Path	✓		
Add BRT along I-290	✓		
Add BRT along east-west arterials		✓	
Improve existing commuter rail		✓	
New commuter rail service		✓	
Convert the existing CTA Blue Line to BRT	✓		
Remove the existing CTA Blue Line		✓	
Add High Speed Rail		✓	
Add Inner Circumferential Commuter Rail		✓	
Express Bus	✓		
Add Automated Guideway Transit		✓	
Add Light Rail Transit		✓	
Related Improvements (that can be combined with other concepts)			
Add express bus service within the project area			✓
Interchange improvements and design			✓
Improve non-motorized facilities			✓
Improve transit stations			✓
Improve transit operations/connections			✓
Add Transportation System Management /Active Traffic Management/Intelligent Transportation Systems			✓
Add a cap over the expressway			✓
Double-deck I-290		✓	
CTA Blue Line in Subway/Tunnel or Elevated			✓
Arterial Improvements			✓
Other			✓
Category Totals	11	11	11

Of the 33 original categories, 11 concept categories were carried forward for consideration in Round 1 evaluation. 11 concept categories of related improvements, as identified Table 4-1, were deferred for consideration in subsequent evaluation steps (i.e. Rounds 2, 3, or DEIS). The

rationale for carrying forward, not carrying forward, or deferring concept categories to subsequent evaluation is provided in Appendix A.

5.0 Round 1 Evaluation Findings

The results of the Round 1 screening evaluation are presented below. Section 5.1 presents the list of initial single mode alternatives identified for Round 1 evaluation, Section 5.2 presents the footprint and flaw analysis results, Section 5.3 presents the results of the travel benefit evaluation, and Section 5.4 summarizes the findings and overall conclusions of the Round 1 evaluation.

5.1 Initial Single Mode Alternatives

Twenty-one single mode alternative concepts, that are derivative of the 11 single mode concept categories carried forward from the pre-screening (see Appendix A), were developed by the study team and Corridor Advisory Group for evaluation in Round 1 that are derived The 21 single mode alternatives are summarized in Table 5-1 through Table 5-3. Some of the concept categories resulted in multiple single mode alternatives. For example, three versions of the CTA Blue Line extension concept were carried forward as single mode alternatives with different project termini.

Table 5-1. Transit Modes Evaluated in Round 1

Mode	ID	Description
Blue Line Extension (Heavy Rail Transit - HRT) 	HRT 1	From Forest Park CTA Terminal to Oak Brook via IL Prairie Path, Butterfield Road, and 22nd Street (elevated) from Forest Park CTA
	HRT 2	Terminal to Oak Brook via I-290 median (at-grade) and parallel to I-88 (elevated)
	HRT 3	From Forest Park CTA Terminal to Mannheim via I-290 median (at-grade)
Express Bus 	EXP	Various service from DuPage and northwest Cook counties to Forest Park CTA terminal
Bus Rapid Transit (BRT) 	BRT 1	Oak Brook to Forest Park CTA Terminal - via Butterfield Road and IL Prairie Path
	BRT 2	Oak Brook to Forest Park CTA Terminal – parallel to I-88 (elevated) and I-290 median (at-grade)
	BRT 3	Oak Brook to Cicero Avenue – Parallel to I-88 (elevated) and I-290 median (at-grade)
	BRT 4	Oak Brook to Ashland Ave – parallel to I-88 and along I-290 median (at-grade) – CTA Blue Line conversion to BRT from Forest Park CTA terminal to Ashland Avenue
	BRT 5	Lombard to Forest Park CTA Terminal – parallel to I-88 (elevated) and along I-290 median (at-grade)

Table 5-2. Expressway Modes Evaluated in Round 1

General Purpose (GP) Add Lane			GP LANE	General Purpose Add Lane from I-88 to Central Avenue
Managed Lanes	**HOV Lanes**	2+ Riders	HOV 2LL	Oak Brook to Racine Avenue
			HOV 2L	I-88 to Racine Avenue
			HOV 2W	Oak Brook to Central Avenue
		3+ Riders	HOV 3LL	Oak Brook to Racine Avenue
			HOV 3L	I-88 to Racine Avenue
			HOV 3W	Oak Brook to Central Avenue
	HOT Lanes		HOT 1	Oak Brook to Central Avenue, 3+ Vehicles Free
			HOT 2	Oak Brook to Racine, 3+ Vehicles Free
	Toll Lanes		TOLL 1	Toll Existing I-290 Lanes, I-88 to Cicero Avenue
			TOLL 2	Toll I-290 with Add Lanes , I-88 to Cicero Avenue

Both the HOV and HOT alternatives assume that two existing general purpose lanes (one in each direction) would be converted to HOV/HOT lane along I-88, and along I-290 from Central Avenue to Racine Avenue. Along I-290 from the I-88/290 split to Central Avenue, two new HOT/HOV lanes (one in each direction) would be added to the existing lanes. Appendix C presents a set of maps representing the single mode alternatives listed above.

Table 5-3. Arterial Improvements Evaluated in Round 1

Arterial Widening	With Parking	ART 1	Widening of Roosevelt Road and Madison Avenue to 4 continuous lanes (2 lanes each direction). Roosevelt Road from I-294 to Cicero Avenue Madison Avenue from 25th Avenue to Cicero Avenue
	Without Parking	ART 2	

5.2 Footprint and Fatal Flaw Screening Results

Corridor level right of way footprints were evaluated and assessed to determine if there were any significant potential impacts that would result in that alternative being fatally flawed due to impacts or displacements. Corridor level footprints included only the main trunk of the alternative, and did not include interchanges, intersection improvements or other localized components, such as park-and-ride lots that will be determined in subsequent rounds of development. The footprint, or width of the alternative, was based on common design standards for each mode.

Corridor level footprint impacts were evaluated along any portion of an alignment that extended west of the DesPlaines River. West of the river, alternatives alignment locations were

relatively straightforward with fewer constraint variables affecting their locations. East of the DesPlaines River, all the alternative alignments generally follow along the existing I-290 corridor, with the exception of arterial improvements. In this section, two important constraint variables that could directly affect the footprint location are still unresolved at this time, the availability of CSX right-of-way on the south side of I-290. Because this variable could affect how an alternative may be physically accommodated in this area, none of the expressway alternatives were fatally flawed in Round 1 due to footprint impacts.

The results of Round 1 footprint screening indicated that the arterial widening alternatives were fatally flawed because of the number of displacements. Due to the very mature and dense urban environment along Roosevelt Road and Madison Avenue, arterial improvements along these routes would involve widening (from two to four lanes where a two-lane section exists) between Mannheim Road and Cicero Avenue. This would result in between 356 to 583 direct impacts to buildings (for widening without and with parallel parking, respectively). For this reason, arterial widening was dropped for further consideration in the alternatives evaluation. Other arterial suggestions may emerge in subsequent rounds and will be considered as appropriate. The summary table of these results and supporting evaluation exhibits maps can be found in Appendix E.

5.3 Travel Benefit Evaluation

Round 1 is intended to evaluate the transportation performance characteristics of each single mode prior to assembling combination mode alternatives in Round 2. Although Round 1 is not intended to be purpose and need test, to be consistent with purpose and need, the performance based criteria presented in Section 3.2 were used to evaluate the single mode alternatives performance relative to the 2040 baseline condition. For further detail, please refer to the full results summary matrix for the single mode alternatives in Appendix D. For each evaluation measure, the four single mode alternatives that resulted in the best performance relative to the baseline condition are indicated. This evaluation is intended to be used as a tool for the presentation and assistance in the interpretation of the Round 1 performance evaluation results. The ratings shown are not considered to be an absolute measure for determining which alternatives are eliminated or carried forward but are best used in a comparative analysis between alternatives of similar mode. In addition, many factors are considered when evaluating alternatives, including stakeholder and transportation agency input, costs, impacts, and more.

5.3.1 Improve Regional and Local Travel

The results of the regional and local travel performance evaluation of the single mode alternatives are presented below. In Round 1, 17 transportation performance measures were evaluated, 13 related to regional travel, and 4 related to Local Travel.

5.3.1.1 Improve Regional Travel

Table 5-4 presents the alternatives that resulted in the best improvements in the I-290 performance measures relative to the 2040 No Build condition. The performance measures are specific to the I-290 Eisenhower Expressway.

Table 5-4. I-290 Expressway Travel Ratings

I-290 Expressway Travel Performance Measures	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
I-290 Volume to Capacity (all lanes, peak periods)	TOLL 2	TOLL 1	HOV 3LL	HOV 3W
% change relative to baseline	-7.85%	-5.98%	-5.95%	-5.69%
I-290 Average Speeds (all lanes, peak periods)	TOLL 2	TOLL 1	HOV 2LL	HOV 2W
% change relative to baseline	+35.45%	+28.12%	+15.30%	+14.94%
I-290 Average Travel Time Changes (all lanes, peak periods)	TOLL 2	TOLL 1	HOV 2LL	HOV 2W
% change relative to baseline	-26.17%	-21.95%	-13.27%	-13.00%
Daily Hours of Congestion Reduction (I-290 in Study Area)	TOLL 2	HOV 2W	HOV 2L	HOV 2LL
% change relative to baseline	-22.22%	-5.56%	-5.56%	-5.56%

All the expressway single-mode alternatives resulted in an improvement of the I-290 performance travel measures relative to the 2040 No Build conditions. Tolling alternatives experience the highest expressway performance increases because tolls increase user costs, discouraging some users from the expressway and reducing overall traffic on I-290, however local arterial performance decreases due to diversions from the expressway. HOV alternatives also perform well because they manage the demand for the added capacity, providing travel time reductions over 40 percent in the HOV lanes and over 10 percent increase in the adjoining 3 general purpose lanes through the study area compared to the travel times for the existing 3 general purpose lanes[2]. The transit alternatives resulted in no performance improvements on I-290 relative to the 2040 baseline condition in all of the above categories because there was insufficient diversion from auto to transit to have an impact on I-290 congestion. Transit is also serving a smaller, more compact market, as shown later in Figure 5-2.

The tolling alternatives provided the best overall improvement (all lanes) in V/C, speed, and travel time during the peak periods, but the HOV alternatives provided the most improvement in travel times and speeds, with speeds in the HOV lanes showing improvements ranging from 40 percent to 55 percent over the 2040 baseline condition. The HOT alternatives also showed good improvement in peak period travel times and speeds in the HOT lanes. The volumes in the general purpose lanes also decrease between 7 and 10 percent when a managed lane is added to the corridor. This is due to the added managed lane capacity addressing a saturated,

[2] See Appendix D – Summary of Single mode Evaluation Results: Measure 1.3 – I-290 Average Travel Time Changes (peak periods)

constrained condition on I-290 and existing and newly formed carpools diverting to the manage lane.

All of the expressway alternatives, which add capacity on I-290 (between Mannheim Road and Central Avenue) as General Purpose, HOV, HOT, or toll lanes, resulted in improved travel performance on I-290. All of the transit alternatives resulted in no improvements travel performance on I-290, since they provide for no capacity improvement on I-290, nor generate enough diversions to transit to offset the unmet vehicle demand for the facility.

Table 5-5 presents the alternatives that resulted in the best improvements in Daily Person Throughput (through the study area) relative to the 2040 No Build condition. Daily Person Throughput measures the number of persons in autos and transit vehicles (including both bus and rail vehicles) moving through the study area in an east-west direction.

Table 5-5. Daily Person Throughput Ratings

I-290 Study Area East-West Person Throughput	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
Daily Person Throughput (through study area)	 HOV 3LL	 HOT 1	 HOV 3L	 HOT 2
% change relative to baseline	+7.31%	+7.11%	+6.87%	+6.82%

HOV/HOT alternatives provide the best overall improvement in person throughput. BRT, HRT, General Purpose and Toll 1 provided some improvement, while Toll 2 provided the least improvement in daily throughput.

Added capacity on I-290 in the form of managed lanes that give preferential treatment to carpools (HOV/HOT) were the alternatives that carried the most people through the study area in an east-west direction. This is due to both the increased I-290 capacity due to the additional HOV/HOT lane, and more efficient throughput of vehicles carrying multiple occupants. Transit alternatives increase the capacity of transit in the study area, which results in some new riders that have diverted from auto. However, transit alternatives also result in a more significant diversion of passengers from existing parallel bus and rail services, limiting the overall increase in person throughput. Adding capacity on I-290 in the form of general purpose or toll lanes improves person throughput, but not to the extent of HOV/HOT because there are no incentives for auto vehicles to carry more occupants.

Table 5-6 presents the alternatives that resulted in the best overall improvements in overall regional performance measures. These evaluation measures are for all roadways in the CMAP model area, which covers 22 counties in 3 states, of which 11 counties in northeast Illinois are reported on.

Table 5-6. Regional Travel Ratings

Regional Travel Performance Measures	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
Vehicle Miles of Travel (VMT) (daily, regional)	HOV 3LL	HOV 3L	HOV 3W	HRT 1
% change relative to baseline	-0.07%	-0.07%	-0.06%	-0.03%
Vehicle Hours of Travel (VHT) (daily, regional)	HOV 3W	HOV 3LL	HOV 3L	HOV 2W
% change relative to baseline	-0.24%	-0.22%	-0.22%	-0.18%
Congested VMT (daily, regional)	TOLL 2	HOV 3W	HOV 3LL	HOV 3L
% change relative to baseline	-0.47%	-0.46%	-0.45%	-0.42%
Hours of Delay (daily, regional)	HOV 3W	HOV 3L	HOV 3LL	TOLL 2
% change relative to baseline	-0.40%	-0.37%	-0.37%	-0.35%

Daily Vehicle Miles of Travel (VMT) represents the total distance per day traveled by all vehicles in the CMAP region. Daily VMT declines versus the 2040 baseline condition for HOV 3+ and the transit alternatives. HOT, General Purpose, and Toll alternatives resulted in increased VMT. The efficient use of auto in the form of a 3-person (or more) carpool more than offsets the increase in VMT by generally using a slightly longer, but faster route provided by the HOV lane. The HOT, General Purpose, and Toll alternatives result in increased VMT because the auto trips are overall slightly longer to use the additional expressway capacity provided on I-290, but are overall faster trips. Transit alternatives resulted in persons diverting from autos, resulting in less VMT.

Daily Vehicle Hours Traveled (VHT) is the total time spent traveling by all vehicles in the CMAP region, and is an important measure because travel time savings result in economic benefits. Compared to the 2040 baseline condition, HOV 3+ resulted in the largest reduction in VHT, followed by the other expressway alternatives. The transit alternatives showed some reduction in VHT, however the reductions were approximately a third of that provided by the expressway alternatives on average. For the expressway alternatives, VHT savings ranged from 12,000 to 24,000 hours per day.

Congested VMT and Hours of Delay are considered measures of congestion for the CMAP region. HOV 3+ and Toll 2 resulted in the most improvement in Congested VMT and Hours of Delay, followed by the other expressway alternatives. The transit alternatives showed some reduction in these congested measures, but were generally one-fourth of the reduction provided by the expressway alternatives.

Table 5-7 presents the alternatives that resulted in the best improvements in the regional truck travel performance measures relative to the 2040 baseline condition. Travel time is an important measure for trucks, as the value of time is typically higher for trucks than autos, reflecting the value of goods being transported. Regional truck travel time performance measures include truck hours of travel (THT) and truck hours of delay.

Table 5-7. Regional Truck Travel Ratings

Regional Truck Travel Performance Measures	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
Truck Miles of Travel (TMT) (daily, regional)	HOV 3LL	HOV 3L	BRT 4	TOLL 1
% change relative to baseline	-0.02%	-0.01%	-0.01%	-0.01%
Truck Hours of Travel (THT) (daily, regional)	TOLL 2	TOLL 1	GP LANE	HOT 2
% change relative to baseline	-0.66%	-0.50%	-0.16%	-0.14%
Congested TMT (daily, regional)	TOLL 2	HOT 2	HOT 1	TOLL 1
% change relative to baseline	-0.70%	-0.57%	-0.47%	-0.37%
Truck Hours of Delay (daily, regional)	TOLL 2	GP LANE	HOT 2	HOT 1
% change relative to baseline	-0.51%	-0.29%	-0.26%	-0.24%

Overall, the Toll, HOT, and General Purpose alternatives showed the most improvement in THT, Congested TMT, and Truck Hours of Delay. HOV and transit also showed improvement in these regional measures for trucks.

5.3.1.2 Improve Local Travel

Table 5-8 presents the alternatives that resulted in the best improvements in the Arterial travel performance measures relative to the 2040 No Build condition in the study area. Arterial Volume to Capacity represents how many vehicles are traveling on an arterial as compared to how many vehicles the arterial can accommodate. At volume to capacity approaching one, the arterials are very congested.

Table 5-8. Arterial Travel Ratings

Study Area Arterial Travel Performance Measures		Top 4 Performing Alternatives Overall			
		1st	2nd	3rd	4th
Arterial Peak Period Volume To Capacity	East-West Arterials	GP LANE	HOV 2LL	HOV 2W	HOT 2
	% change relative to baseline	-4.57%	-3.90%	-3.78%	-3.48%
	North-South Arterials	GP LANE	HOV 2LL	HOV 2W	HOT 2
	% change relative to baseline	-4.50%	-4.01%	-3.87%	-3.86%
Arterial Peak Period Speeds	East-West Arterials	GP LANE	HOV 2LL	HOV 2W	HOV 2L
	% change relative to baseline	+2.52%	+2.45%	+2.34%	+2.28%
	North-South Arterials	HOV 3L	HOV 3LL	BRT 4	HRT 1
	% change relative to baseline	+0.39%	+0.38%	+0.35%	+0.30%

The General Purpose, HOV 2+, and HOT alternatives were the best performing with regards to improving study area arterial travel performance by lowering arterial peak period Volume to Capacity and improving east-west arterial peak period speeds in the study area. The transit alternatives resulted in slightly worse arterial travel performance in the east-west direction.

General Purpose, HOV, BRT, and the transit alternatives showed the most improvements for study area north-south arterials as compared to the 2040 baseline condition.

Generally, east-west arterial travel improvements are seen when capacity improvements are included along I-290, however there is a correlation between the east-west arterial improvements and how the added capacity of the expressway alternative is managed. The less the added capacity to I-290 is managed (General Purpose lanes, with no usage restrictions), the better the performance of the parallel east-west arterials. This is because longer distance trips that were previously using the east-west arterial streets are now using the added capacity on the I-290 Expressway. Since the General Purpose lanes had no requirements for using this added capacity on I-290, it attracted the most longer-distance trips off of the east-west arterials, with more than a 62,000 vehicle miles of travel decrease on study area arterial streets.

Table 5-9 presents the alternatives that resulted in the best improvements in the Local Travel performance measures relative to the 2040 baseline condition. These travel performance measures show which alternatives provide the most travel performance improvement to the study area only.

Table 5-9. Study Area Travel Ratings

Study Area Travel Performance Measures	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
Arterial Vehicle Miles of Travel (VMT)	GP LANE	HOT 2	HOV 2W	HOT 1
% change relative to baseline	-1.85%	-1.73%	-1.26%	-1.24%
Arterial Vehicle Hours of Travel (VHT) (daily, regional)	HOT 2	GP LANE	HOV 3LL	HOV 2LL
% change relative to baseline	-3.16%	-2.76%	-2.71%	-2.58%
Arterial Congested VMT (daily, regional)	HOT 2	HOV 3LL	HOV 2LL	HOV 3L
% change relative to baseline	-8.10%	-7.45%	-7.13%	-7.11%
Arterial Hours of Delay (daily, regional)	HOT 2	HOV 3LL	HOV 3L	HOV 2LL
% change relative to baseline	-4.69%	-4.48%	-4.34%	-4.02%

The HOT, General Purpose and HOV alternatives result in the most improvement to study area travel performance. The transit alternatives provide some improvement, while the Toll alternatives result in worsening of arterial travel performance in the study area without additional capacity being added.

A comparison of the Study Area Travel Performance Measures table with the Regional Travel Performance Measures table shows that the General Purpose and HOT alternatives provide more benefit to the study area, but overall at the regional level, HOV provides the most benefit.

5.3.2 Improve Accessibility to Employment

Table 5-10 presents the alternatives that resulted in the best improvements in the Access to Employment performance measures relative to the 2040 No Build condition. Changes to the number of jobs accessible by automobile and transit reflect the changes in travel times due to the transportation performance effects of the single mode alternative being evaluated; the faster the travel time, the more jobs accessible within a given time frame.

Table 5-10. Jobs Accessibility Ratings

# of Jobs Accessible within 60 Minutes	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
By Auto	TOLL 2	HOT 2	TOLL 1	HOV 3LL
% change relative to baseline	+10.75%	+9.28%	+6.95%	+5.41%
By Transit	BRT 4	BRT 5	BRT 2	BRT 3
% change relative to baseline	+13.44%	+8.45%	+7.81%	+7.11%
By Auto & Transit	TOLL 2	HOT 2	BRT 4	TOLL 1
% change relative to baseline	+6.31%	+5.44%	+5.31%	+4.08%

The number of jobs accessible within 60 minutes from a point in the center of the study area by auto, transit, and combined were calculated for each alternative. The expressway modes show the best improvements in job access by auto, and transit had the best improvements in job access by transit. However the single mode transit alternatives generally worsened the number of jobs accessible by auto, which correlates to decreases in I-290 performance exhibited by the transit alternatives.

When considering the total number of jobs accessible by auto and transit for each single mode alternative, Toll and HOT provide the best access, followed by the BRT. Access to jobs would likely increase with combination expressway and transit alternatives, which will be identified and evaluated in the next screening step.

5.3.3 Improve Safety for All Users

The initial single mode alternatives were compared relative to the 2040 baseline condition for the third need point, improve safety for all users, of the Purpose and Need. Injury and fatal crashes per million vehicle miles traveled (per year) for arterials and expressways were calculated using the AASHTO HSM and the Texas Roadway Safety Manual methodologies, respectively. Injury and fatal crashes per million person miles traveled (per year) on arterial, expressways, and transit were estimated for each alternative. The overall measure accounts for transit safety by assuming no injuries or fatalities for transit person miles. The percent change in injury and fatality rates relative to the 2040 baseline condition were then compared. An expanded summary table for the Round 1 safety evaluation can be found in Appendix D. The top four performing single mode alternatives for improving arterial, I-290, and overall safety are shown in Table 5-11.

Table 5-11. Safety Improvement Ratings

Reductions in Injuries and Fatalities % Rates of Change	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
Arterials	 BRT 4	 GP LANE	 HRT 2	 BRT 5
% change relative to baseline	-0.13%	-0.10%	-0.10%	-0.09%
Expressway (I-290)	 TOLL 2	 HOV 3L	 HOV 3LL	 HOV 3W
% change relative to baseline	-14.36%	-14.21%	-14.19%	-13.58%
Overall (Arterials, Expressways, Transit)	 HOV 3LL	 HOV 3L	 HOV 3W	 HOV 2L
% change relative to baseline	-11.51%	-11.06%	-9.58%	-8.66%

For arterials, the HSM evaluation indicates there is a relatively stable total number of injury and fatal crashes per year across the alternatives ranging from between -3 percent decrease (GP LANE) and 1 percent increase (TOLL 2), compared to the total number of injuries and fatalities of the 2040 baseline condition (263.9). With the exception of the TOLL 2 alternative, all the expressway alternatives showed overall reductions in total injury crashes. For transit alternatives, the analysis indicated slight increases in these types of crashes, with the exception of HRT 3. However, when expressed as a rate of crashes per million vehicle miles traveled, the transit options indicate some reduction in crashes. This is due to a higher increase in vehicle miles traveled compared to a relatively similar total number of crashes. Although the GP LANE alternative ranks 2nd, it had the lowest total number of crashes overall coupled with the lowest number of vehicle miles traveled on the Arterials.

Regarding the safety of I-290, the HOV and TOLL alternatives showed reductions in total number of annual injury and fatal crashes (between -1.1 percent and -14.1 percent) as compared to the 2040 base condition. When expressed as a rate of crashes per million vehicle miles traveled (per year), all the expressway alternatives indicate good safety improvements with crash reductions ranging from -9.6 percent (HOT 2) to -14.4 percent (TOLL 2). All the transit alternatives indicated an increase in total number of crashes and related increases in crash rates.

Overall safety factors in all the projected annual injury and fatal crashes on arterials, expressways, and transit, and divides by the total number of person miles traveled on these facilities in the study area.

Comparing the overall safety performance of the arterials, expressways, and transit in the study area, all the alternatives demonstrated an improvement in safety using person miles traveled as a basis. With the exception of TOLL 1, all the expressway alternatives indicate the highest overall safety improvements, ranging between -5.2 percent (GP LANE) and -11.5 percent

(HOV3 LL) reductions in crash rates. These higher crash rate reductions experienced by the expressway alternatives are due to higher person throughput, combined with overall reductions in these crash types.

5.3.4 Improve Modal Connections and Opportunities

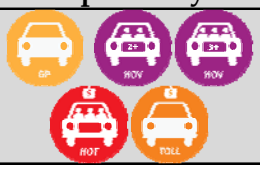
The initial single mode alternatives were compared relative to the 2040 baseline condition for their ability to attract new transit trips, and the top four performing single mode alternatives are shown in **Table 5-12**. New transit trips represent the number of persons that previously used automobiles and have now switched to transit because of the transit improvement.

For the Round 1 Screening, measures of improving transit access, non-motorized connections and multimodal opportunities were not evaluated. As the alternatives are detailed and refined in later screening rounds, a more robust assessment will be made of these evaluation criteria.

Table 5-12. Modal Connections Ratings

Improve Modal Connections and Opportunities	Top 4 Performing Alternatives Overall			
	1st	2nd	3rd	4th
New Transit Trips (Regional)	BRT 3	BRT 5	BRT 4	BRT 2
Transit Access (qualitative)	*Not used*			
Non-Motorized Connections (qualitative)	*Not used*			
Multi-Modal Opportunities (qualitative)	*Not used*			

The BRT alternatives are the best performing alternatives for attracting new transit trips, followed closely by the Blue Line extensions. This level of new transit trips is within the bounds of other proposed transit extensions in the region.



It is also informative to examine the diversion of transit riders to auto that result with the expressway alternatives. With the expressway capacity improvements, there are some transit riders that are switching to auto. In general, the HOV and HOT single mode alternatives indicated some transit riders switching to auto (up to 6,800, and 3,200 transit diversions, respectively). The General Purpose and Toll alternatives had relatively no impact on transit.

5.3.5 Improve Facility Deficiencies

The initial single mode alternatives were compared relative to the 2040 baseline condition for the fifth need point of the Purpose and Need, improve facility deficiencies. For the Round 1 Screening, facility deficiencies measures were not used for screening as shown in Table 5-13. As

the alternatives are detailed and refined in later screening rounds, a more robust assessment will be made of these evaluation criteria.

Table 5-13. Facility Improvement Ratings

Improve I-290 Facility Condition and Design	Transit	Expressway
		
Pavement Age	*Not used*	
Structure Deficiencies	*Not used*	
ADA Deficiencies	*Not used*	
Drainage Deficiencies	*Not used*	

Since the expressway alternatives require the complete reconstruction and renewal of the expressway, interchanges, and overpasses, these alternatives would address the identified needs for improving the facility condition and design. As standalone improvements, the single mode transit alternatives would not address these needs as they would not require the reconstruction and renewal of the expressway throughout the entire study area.

5.4 Summary of Findings

Twenty-one single mode alternatives were identified for evaluation in Round 1: nine-transit, 11-expressway, and one arterial.

5.4.1 Transit Mode Findings

Overall, the single mode transit alternatives provide some improvement in regional congestion and safety, although less than the single mode expressway alternatives. They improve transit access to jobs because of improved transit travel times and improved reverse commute options. The transit alternatives also result in up to 11,600 daily auto person trip diversions, but up to 13,000 diversions from other transit services.

The Blue Line extension and BRT alternatives had similar results and had the best travel performance of the single mode transit alternatives. Each showed some improvement in regional and local travel performance measures, the highest increases in access to jobs by transit and the highest number of new transit trips.

When comparing the effectiveness of the length of transit improvements, it was found that of the three Blue Line Extension alternatives evaluated, the results indicated that the majority of the performance improvements were achieved by a Blue line Extension to Mannheim Road as

compared to an extension further west to Oak Brook at less than half the length (3.5 miles vs. 8 miles). Table 5-14 illustrates this comparison for several of the measures evaluated in Round 1.

For example, a Blue Line Extension to Mannheim Road (HRT 3) provides 71 percent of the new jobs accessible, and 89 percent of new regional transit trips vs. an extension to Oak Brook. Also, an HRT terminal at Mannheim may serve as the starting point for a further westward extension of the HRT line.

Table 5-14. Performance Comparison of Blue Line Extensions

Performance Comparison* of Blue Line Extensions to:	Alignment Length (miles)	Daily Person Throughput	Regional Vehicle Miles Traveled	Regional Hours of Delay (Daily)	# of Jobs Accessible Increase	Overall Safety Improvements (Injury crash reductions)	New Transit Trips (Regional)
	Miles	# persons	Miles	Hours	# Jobs	Crash Rate	# trips
Oak Brook (HRT 2)	8	13,812	-37,362	-3,055	128,032	-3.37%	8,353
Mannheim Rd (HRT 3)	3.5	9,552	-35,438	-4,371	91,328	-2.25%	7,456
HRT 3 as % of HRT 2	44%	69%	95%	143%	71%	67%	89%

* from Round 1 single mode evaluation results

Although not fatally flawed due to impacts, the Blue Line Extension and BRT Alternative along the Prairie Path (HRT 1 and BRT 1) are not being carried forward into Round 2 for further evaluation. The Blue Line extension and BRT alternatives along the Prairie Path and along I-290 (HRT 2) perform very similarly. However the Prairie Path alignment has greater service overlap/duplication with the existing Metra service, diverting more riders from the UP-West line than the alignment along I-290. There are also potential conflicts with the recreational functions of the Illinois Prairie Path corridor which would be considered 4(f) lands. Therefore, the alternatives using the Prairie Path alignment are not being carried forward for evaluation in Round 2.

The BRT 4 Alternative from Oak Brook to Ashland Avenue was evaluated as a conversion of the existing CTA Blue Line to a Bus Rapid Transit facility between Ashland Avenue and the Forest Park terminal. This alternative indicated generally similar and some improved performance as compared to an HRT Blue Line extension to Oak Brook (HRT 2), however, due to the similarity in performance and ROW requirements for these two fixed guideway transit facilities, the HRT extension of the Blue Line will be the representative mode that will be modeled and evaluated in the combination alternatives.

Overall, the single mode transit alternatives do not improve I-290 travel performance as compared to the 2040 No Build conditions, providing no improvements to volume-to-capacity ratios, speeds and travel times, and hours of congestion. This is due to an already well-established and utilized study area transit network, with new service drawing insufficient auto-

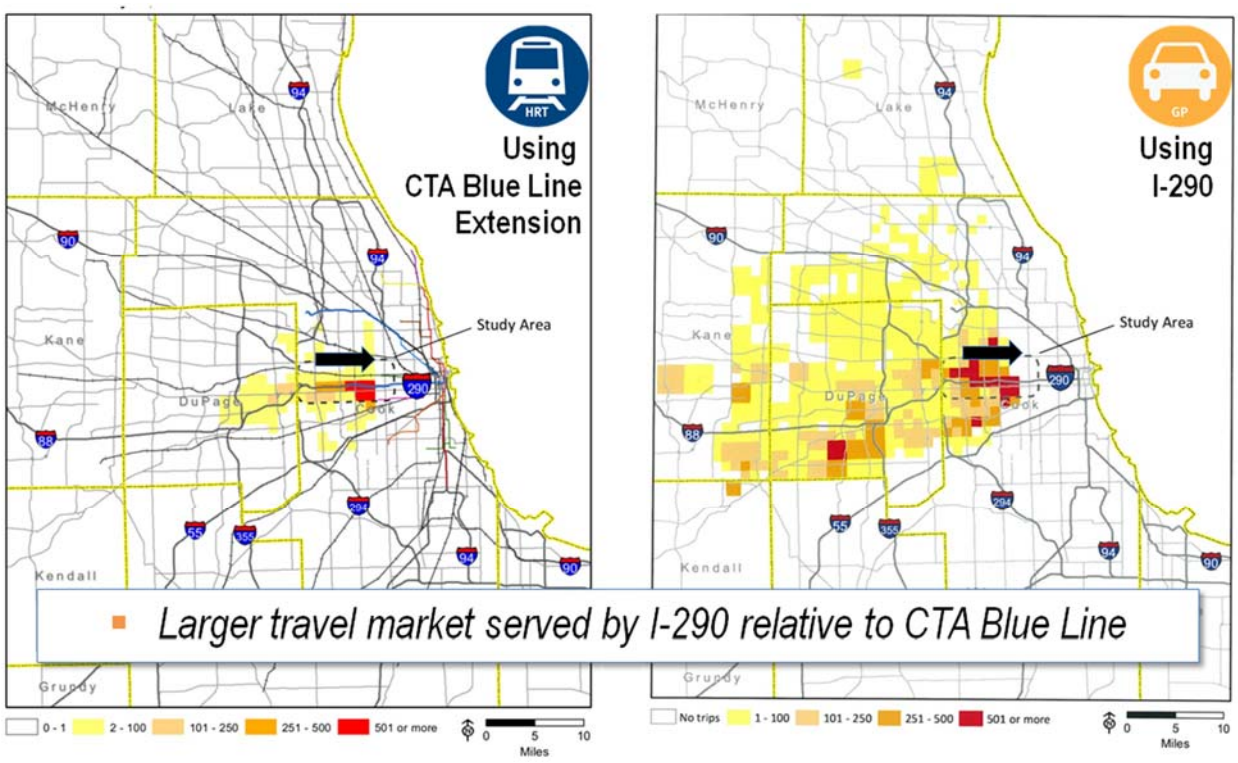
trip diversions to offset auto demand for I-290, and a smaller narrower transit market as compared to I-290.

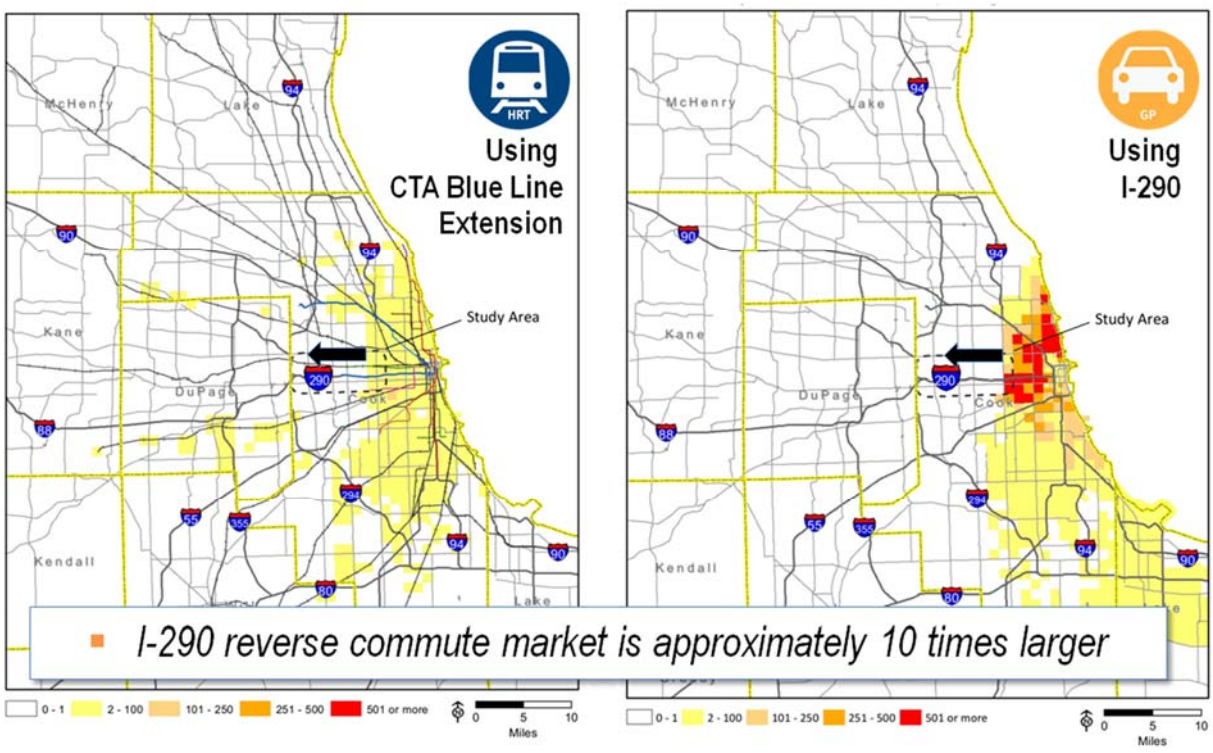
Figure 5-1 and

Figure 5-2 illustrate differences between the transit and expressway travel markets. As seen in Figure 5-1, the travel market for traditional commute (home-to-work) trips is much smaller and confined to the area immediately around the Blue Line extension as compared to using the I-290 Expressway, which has a much broader, more extensive draw of users that extends throughout DuPage County, and into Kane County and northwest Cook County. In the reverse commute direction, shown in

Figure 5-2, the travel market for the Blue Line extension is broader, due to the extensive existing CTA network in the city of Chicago. However, the transit reverse commute travel market is much smaller than the I-290 Expressway at less than a tenth of the size.

Figure 5-1. Traditional Commute Travel Origins





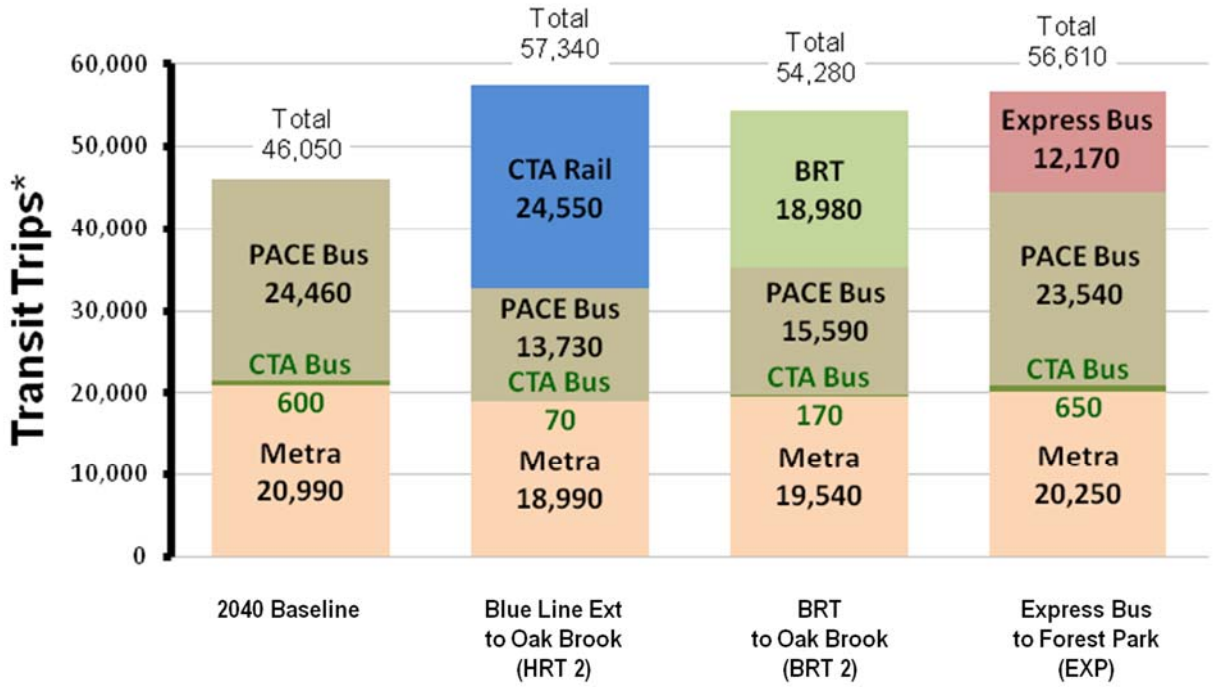


Figure 5-2. Reverse Commute Travel Origins

In addition, new single mode transit service diverts riders from existing transit services. A screen line through the study area was evaluated between 1st Avenue and Des Plaines Avenue in comparison to the east-west transit trips through the study area of three single mode transit alternatives to the baseline condition. As represented in

Figure 5-3, approximately 46,000 transit trips in Pace and CTA buses and on Metra commuter rail trains cross this screen line in the 2040 No Build condition. The Blue Line extension and BRT single mode alternatives to Oak Brook (HRT 2 and BRT 2) result in a diversion of Metra commuter rail trips of up to 2,000 persons, and diversion of Pace and CTA bus riders of up to 11,000 passengers. The ridership on the new Blue Line extension and BRT services is between 19,000 and 25,000 riders, resulting in total screen line crossing of between 54,000 and 57,000 persons. This difference roughly corresponds to the new transit riders (those diverted from auto). Most of the ridership on the new transit service is due to the diversion of trips from other existing transit services. For example, the Blue Line extension to Oak Brook alternative [HRT 2] attracts 24,550 riders, 13,260 (54 percent) of these riders are diverted from existing transit services (PACE, Metra), 8,350 (34 percent) are diversions from auto, and the remaining 2,940 are additional transit trips.

Figure 5-3. Trip Diversions within Transit Modes

In summary, the Blue Line extension and BRT single mode alternatives were the best performing transit alternatives with similar results; however, no single mode transit alternative showed improvement to I-290 travel performance. Regarding an extension of the existing CTA Blue Line, an extension to Mannheim Road would be more cost effective than longer extensions, and therefore Mannheim Road will be the west terminus evaluated in Round 2. The conversion of the existing Blue Line from Forest Park to Ashland to BRT combined with an extension to Oak Brook performed well, but didn't perform appreciably better than HRT so HRT was carried forward as the representative transit. The express bus alternatives resulted in local travel and job accessibility improvements.

5.4.2 Expressway Mode Findings

Overall, the single mode expressway alternatives provide the highest improvement in regional and local (study area) travel performance, and on the I-290 Expressway. They also improve auto access to jobs because of the added capacity that results in reduced time spent traveling. The expressway alternatives also result in up to 6,800 daily transit person trip diversions to auto.

The General Purpose alternative has the best study area peak period arterial performance improvement. The HOV Lane alternatives show the best overall regional travel performance improvement and overall job accessibility improvement. The HOV and HOT Lane alternatives have the best overall performance and person throughput. The Toll and HOV Lane alternatives have the best I-290 travel performance improvements in terms of peak period volume-capacity improvement, peak period average speed increase, and hours of congestion reductions. The

Toll and HOT Lane alternatives have the best auto safety improvement and best regional truck performance improvement.

In comparing volumes for the existing I-290 Expressway general purpose lanes for the expressway alternatives in Table 5-15 below, the daily general purpose lane volumes associated with HOV, HOT, and Toll alternative decrease 7 to 10 percent, while the General Purpose lane alternative, (with the added lane in each direction) results in a 14 percent increase in daily volume.

Table 5-15. Expressway General Purpose and Managed Lane Performance

Study Area Performance		2+ HOV Oak Brook to Racine	3+ HOV Oak Brook to Racine	3+ HOT Oak Brook to Racine	General Purpose Add Lane	Toll I-290 Existing Lanes I-88 to Cicero
		HOV 2LL	HOV 3LL	HOT 2	GP LANE	TOLL1
General Purpose Lanes Daily Volume **		-8%	-7%	-7%	14%	-10%
HOV/HOT Lanes	Daily Volume	31,000	17,600	43,700		
	Peak Hr. Volume	2,930	1,970	3,730		
	Peak Hr. Speed**	67%	112%	17%		

The travel performance of the HOV and HOT lanes in the expressway alternatives is also shown in the Table 5-15. With 1,970 peak hour volume (both directions) for the HOV 3+ lanes, there is a concern that the HOV 3+ lanes may not be fully utilized given capacity of over 4,200 vehicles per hour (2,100 vehicles per hour in each direction). The HOT Lane alternative shows the highest volume, due to excess capacity being utilized by vehicles that may pay a toll to access the lane. The overall peak hour travel speeds of all lanes in the HOV and HOT alternatives also provide improvements compared to the overall speeds of the General Purpose lane alternative. The HOT Lane alternative showed 14 percent speed improvement during the peak hour. However, this can be managed to a greater degree through setting of the dynamic toll rates for the HOT lane.

In summary, the single mode expressway alternatives resulted in the highest travel performance improvements to the I-290 Expressway, as well as the best improvement of regional and local (study area) travel performance. The HOV and HOT Lane alternatives have the best overall performance. The HOV Lane alternatives have the best regional travel performance and job accessibility, and the Toll and HOV Lane alternatives have the best improvement in I-290 Expressway performance. The Toll and HOT Lane alternatives have the best regional truck performance. The Toll alternatives show the least arterial performance

improvements among the expressway alternatives. The General Purpose lane alternative has the best improvement in study area peak period arterial performance.

5.4.3 Arterial Mode Findings

An initial fatal flaw footprint impact evaluation found that the arterial widening (with and without parking) resulted in a large number of displacements and, therefore, arterial widening was determined to be fatally flawed and not carried forward for performance evaluations. Less extensive arterial improvements in conjunction with other modes may be considered in subsequent rounds.

5.4.4 Overall Conclusions

The I-290 Study Area is an existing multi-modal corridor that serves broad travel markets to the east and west of the study area. To the east, the primary travel markets served by this corridor extend to the city of Chicago, the Chicago Central Business District, suburban Cook County, and Lake County, Indiana. To the west the I-290 Corridor serves the markets of west and northwest Cook County, DuPage County, and Kane County. These markets include the auto and transit markets, with the auto travel market being much broader and larger. The traditional commute is the primary market served by transit.

Transit Conclusions

- The transit alternatives provide improved mobility options to areas west of the Forest Park Blue Line station, improved access to jobs, and also diversion of auto users.
- The transit alternatives did not result in any travel performance improvement to the I-290 Expressway.
- When evaluating various single mode transit alternatives, extensions of the existing CTA Blue line with high capacity transit modes of BRT and HRT showed the highest mode shifts and person throughput from auto to transit.
- There was a considerable mode shift between transit modes and no single transit mode alternative was able to shift enough demand from auto to transit to offset the demand on the expressway, and therefore resulted in no improvements to expressway performance.
- Due to the similarity in performance and ROW requirements between the existing Blue Line and a conversion of the existing Blue Line to Bus Rapid Transit (BRT 4) the conversion of the existing Blue Line will not be carried forward.
- Mannheim Road will be the western terminus for Round 2.

Expressway Conclusions

- The expressway alternatives showed the greatest improvement in travel performance for the region, study area and on the I-290 Expressway itself. Due to the size of the expressway travel markets, there is a much higher demand for use of the expressway alternatives than for the transit alternatives. Of the expressway alternatives, the HOV and HOT lane alternatives had the best overall performance, followed by the Toll and General Purpose lane alternatives. The HOV, HOT, and Toll lane alternative resulted in congestion improvements for the existing I-290 general purpose lanes.
- The HOV and HOT lanes showed increased travel speeds over the existing general purpose lanes. Round 1 evaluation, raise a concern as to whether optimal peak period HOV 3+ lane

volumes will occur; additional evaluation will be needed to further evaluate the effectiveness of HOV 2+ and HOV 3+ .

The alternatives showing the best performance relative to the 2040 baseline condition are shown in Table 5-16.

Table 5-16. Single Mode Performance Ratings

Purpose and Need Summary	Top Performing Alternatives						
	1st	2nd			3rd	4th	
Overall	HOV 3LL	HOV 3L	HOT 2	TOLL 2	HOV 2LL	GP LANE	TOLL 1

Overall, managed lane expressway alternatives (HOV and HOT) provide some of the best performance benefits because they address the underserved vehicle travel demand in this corridor, and manage its use more effectively.

5.4.5 Initial Combination Mode Alternatives

Based on the findings of the Round 1 Single mode alternative evaluation, 10 combination mode alternatives were assembled for evaluation in Round 2.

5.4.5.1 Expressway Modes in Combination Alternatives

The stand-alone expressway alternatives resulted in the greatest improvement in travel performance for the region, study area, and along I-290, when compared to the no-build condition The stand alone expressway alternatives also resulted in better performance than stand-alone transit modes (for improving local and regional travel, overall access to employment and safety). Although the stand alone transit alternative did not show the same level of improvements demonstrated by the expressway alternatives, they do offer additional benefits, such as large increases in transit access to jobs, auto person trip diversions to transit, and some improvements in regional congestion and safety. Building on the performance improvements exhibited by the expressway modes and recognizing the additional benefits that transit provides, initial combination mode alternatives were developed to systematically test the transit modes with each highway mode to determine what performance gains may be achieved by various combinations. The following four expressway modes were selected for further testing in combination with the transit modes; HOV, Toll, HOT, and GP Lanes. HOV with 2+ occupants was selected over HOV with 3+ occupants due to greater reduction in general purpose lane volumes and approximately twice the volume in the HOV lanes. However, a decision as to whether to operate HOV 2+ or HOV 3+ will require more detailed operational analyses as the alternatives are continued to be refined.

A fifth expressway combination alternative pairs Toll Lanes and HOT 3+ with transit. This scenario was added to test the combined effects of converting I-290 to a tolled facility, HOT 3+, and transit.

To provide a consistent comparison basis between managed lane alternatives (HOV, HOT, Toll) the eastern and western managed lane/toll limits for each alternative extend from the I-88/I-290 split in the west, and to Racine Avenue in the east. These limits will be revisited depending on the evaluation results, further clarification of tolling/managed lane conversion legislation, and stakeholder input.

5.4.5.2 Transit Modes in Combination Alternatives

Although transit modes do not provide any improvements to I-290 performance, the transit modes are being tested in combination with the expressway modes to evaluate how transit may improve overall transportation performance of the alternatives in the study area and region.

Express Bus service was included as a component in all combination mode alternatives due to its operational and physical compatibility with other modes. Express bus serves a broad market to the west, providing an express connection to the existing Blue Line Terminal in Forest Park, or to a new Heavy Rail Transit (HRT) terminal at Mannheim Road. Express bus may operate on the shoulder in the GP Add Lanes scenario, or in HOV, HOT, or Toll lanes, allowing this mode to integrate readily into the expressway alternatives.

The evaluated single mode transit system extensions from the existing Forest Park CTA Blue Line Terminal included Heavy Rail Transit (HRT) and Bus Rapid Transit (BRT) alternatives, and it was found that both modes are feasible, show similar performance characteristics, and have similar footprint/ROW requirements. For the purposes of Round 2 evaluations, the fixed guideway transit mode will be evaluated as High Capacity Transit (HCT) that could be either HRT or BRT. The I-290 Phase I study is providing a foundation for future detailed studies of this transit improvement, such as a Federal Transit Administration (FTA) Alternatives Analysis (AA) study.

The Mannheim Road terminus for an HCT extension was selected due to the single mode modeling results that suggested, relative to each other, the majority of the performance improvements were achieved by a Blue Line extension to Mannheim Road as compared to an extension further west to Oak Brook at less than half the length. Also, an HCT terminal at Mannheim may serve as the starting point for a further westward extension of the HCT line (Section 5.4.1). Each Expressway & Express Bus transit combination alternatives will be tested with and without High Capacity Transit to systematically evaluate the effects of HRT in each scenario.

5.4.5.3 Initial Combination Mode Alternatives to be Evaluated in Round 2

Combination alternatives have been assembled to analyze the combined performance of transit and expressway alternatives in meeting study area and regional needs. In addition, the compatibility of pairing each of the expressway modes with the transit alternatives must be analyzed with regards to:

- Travel markets: To what degree do the expressway and transit components of these combination alternatives serve complementary or overlapping travel markets? For example, would HOV lanes compete for some of the same users as HRT and to what extent?

- Operations: How well do the expressway and transit components of the combination alternatives work together from an operational perspective? For example, does express bus run on the inside or outside shoulder with the General Purpose lanes, how well would it operate in a managed lane?

The rationale described above resulted in ten initial combination alternatives, which are summarized in Figure 5-4 below. The top five highest performing expressway alternatives were first paired with the EXP single mode transit alternative to form the first five combination mode alternatives. Each of the five Expressway & Express Bus alternatives were then paired with the HCT extension from the Forest Park CTA terminal to Mannheim Road to create the final five alternatives.

Figure 5-4. Initial 10 Combination Mode Alternatives

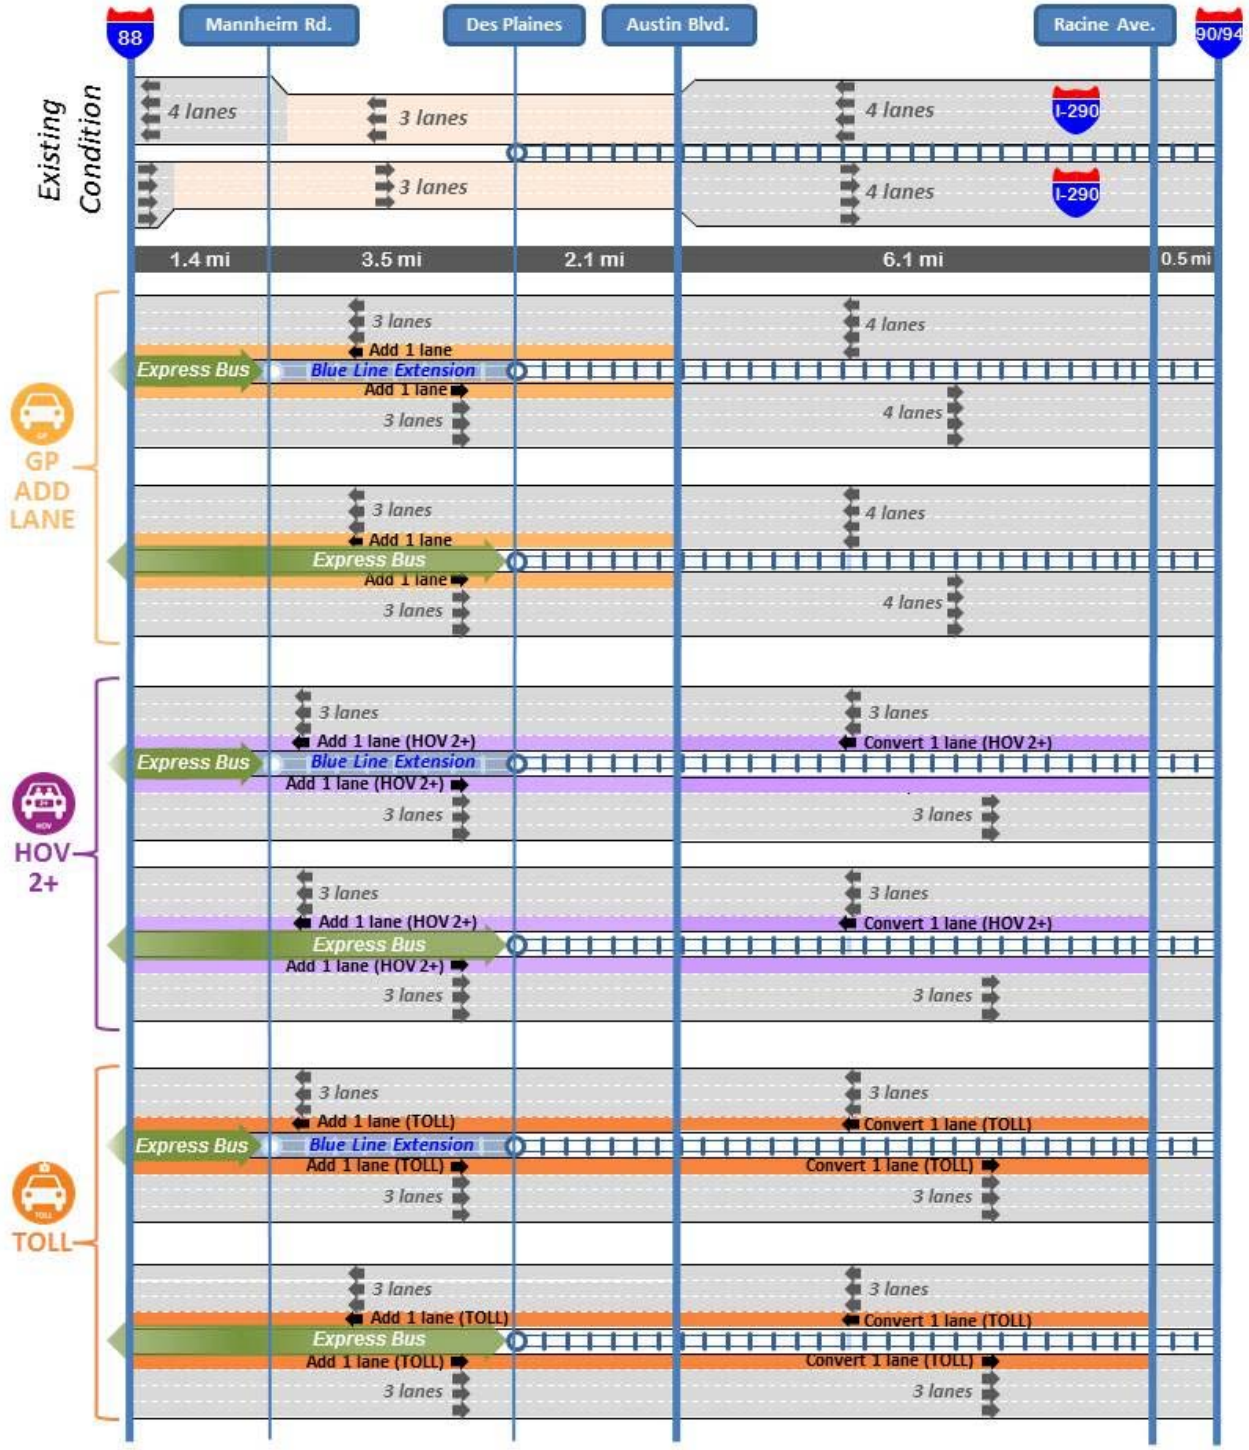

Figure 5-4. Initial 10 Combination Mode Alternatives (Continued)

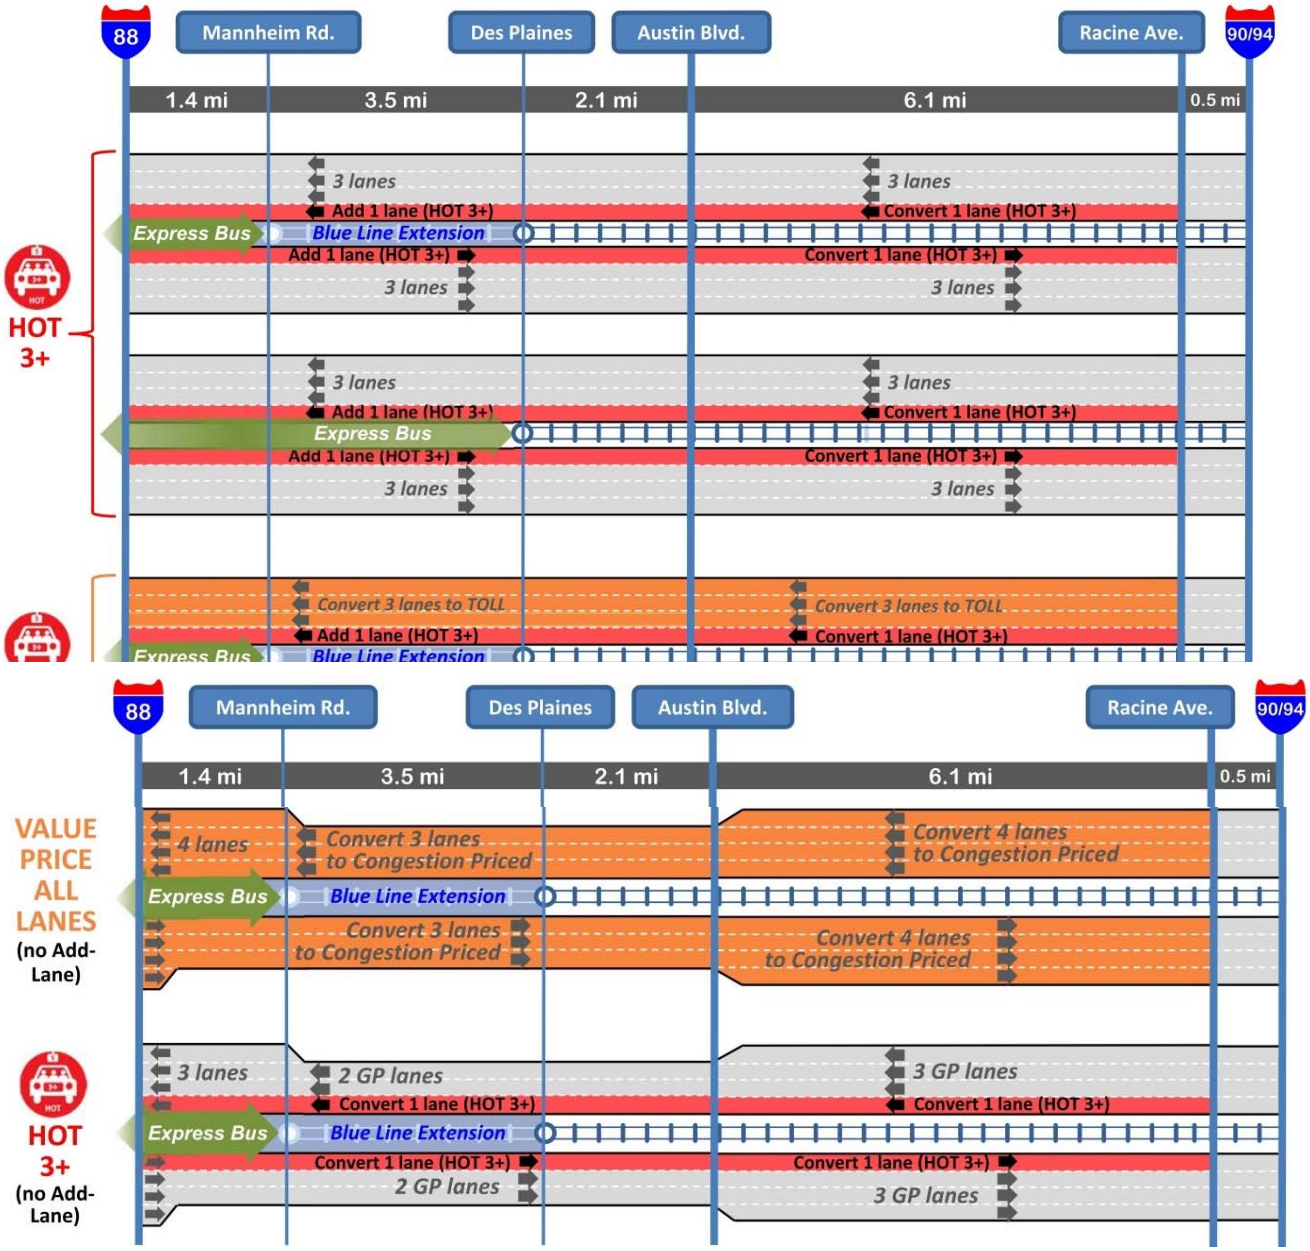

Table 6-1 provides more detailed descriptions of the Round 2 Alternatives evaluated. In Round 2, service and operational characteristics of the alternatives were further defined for evaluation in the project's regional travel forecasting model. Model results were used to evaluate the performance measures in Round 2. General footprint variations of the combination mode alternatives were identified.

With regard to the service and operational characteristics of the 12 combination mode alternatives, the express bus component (EXP) consists of three I-290 express bus services either continuing north on I-290 to serve the northwestern suburbs, heading west on I-88 to serve the western suburbs, and heading south on I-294 to serve the southwestern suburbs. The express bus components were included in all 12 alternatives and have two different termini depending on whether or not an HCT extension is included in the combination mode alternative. In the 5 combination mode alternatives that do not include an HCT extension to the west, the Express bus service connects via I-290 to the existing Forest Park CTA Blue Line Station. For the seven combination mode alternatives that include an HCT extension to Mannheim Road, the express bus service connects to a new CTA terminal located near Mannheim Road (and does not continue further east along I-290).

For the purposes of evaluation with the regional travel model the HCT extension was coded as an extension of the CTA Forest Park Blue Line rapid transit service, however, this service could be also run as bus rapid transit. Intermediate stations at 1st Avenue and 25th Avenue were assumed in each of the 7 HCT extension alternatives. Park-and-ride availability was also assumed at a Mannheim Road terminal station.

The expressway alternatives assumed in the 12 combination mode alternatives include maintaining the existing number of lanes throughout and the addition of a new lane (in each direction) in the existing six-lane section of I-290 between I-88 and Central Avenue for 10 out of the 12 combination mode alternatives. For the managed lane concepts of HOV 2+, HOT 3+, Toll, and HOT 3+ & Toll, a conversion of one of the existing 4 lanes (in each direction) to a managed lane was assumed from Central Avenue to Racine Avenue. Racine Avenue was used as the eastern boundary of this lane conversion in order to allow sufficient traffic operational weaving distance between Racine Avenue and the ramps to I-90/94.

Of the 12 alternatives considered, three general footprint variations result; an expressway lane addition with, and without, a provision for a HCT extension in the median, and maintaining a six lane section but including a provision for an HCT extension in the median. Footprint requirements will be developed and evaluated in Round 3.

The I-290 travel forecasting model was improved for use in testing the Round 2 combination mode alternatives. The regional mode choice model that determines if trips are made using auto or transit was updated to be sensitive to tolling. Therefore, the combination mode alternative results better reflect sensitivity to tolling.

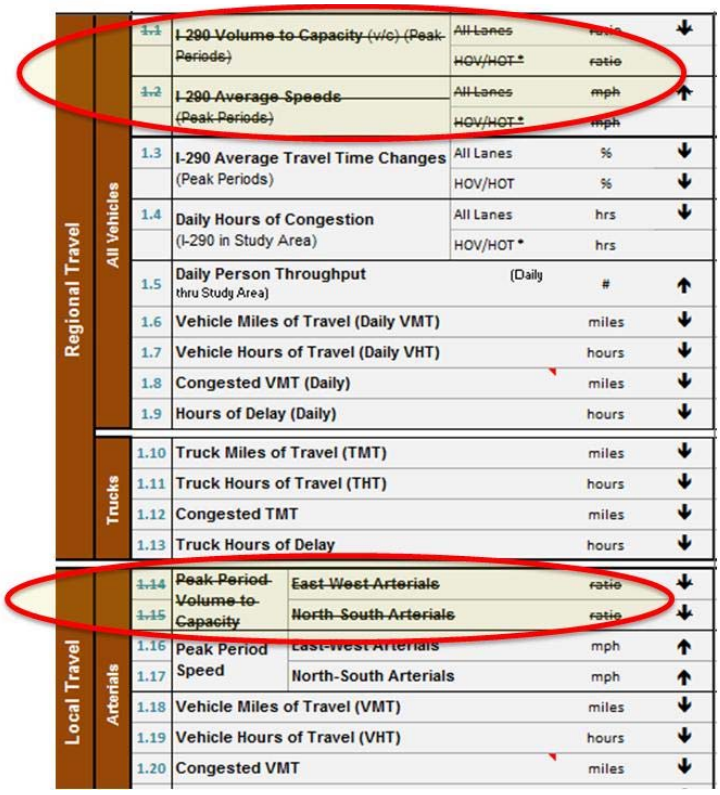
Table 6-1. Combination Mode Alternatives Rationale

10 Initial Combination Alternatives – Summary			Combination Rationale
GP Add Lane		**General Purpose Add Lane** from I-88 to Central Ave. with shoulder riding **Express Bus** from Forest Park to the west	GP Lane: • I-290 performance improvements • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with GP Lane (Bus on shoulder) HRT: • Auto diversions to transit • Job access improvement
		**General Purpose Add Lane** from I-88 to Central Avenue, **HRT** from Forest Park to Mannheim Rd., **Express Bus** from Mannheim Rd. to the west	
HOV 2+		**HOV 2+** from I-88 to Racine Ave., **Express Bus** operating in **HOV Lane** from Forest Park to the west	HOV Lane: • I-290 performance improvements • Manage added capacity • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with HOV Lane (Bus in HOV Lane) HRT: • Auto diversions to transit • Job access improvement
		**HOV 2+** from I-88 to Racine Ave., **HRT** from Forest Park to Mannheim Rd, **Express Bus** from Mannheim Rd. to the west	
HOT 3+		**HOT 3+** from I-88 to Racine Ave., **Express Bus** operating in **HOT Lane** from Forest Park to the west	HOT Lane: • I-290 performance improvements • Manage added capacity • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with HOT Lane (Bus in HOT Lane) HRT: • Auto diversions to transit • Job access improvement
		**HOT 3+** from I-88 to Racine Ave., **HRT** from Forest Park to Mannheim Rd., **Express Bus** from Mannheim Rd. to the west	
TOLL		**Add lane** from I-88 to Central Ave., **Toll 1 lane** in each direction from I-88 to Racine Ave., and **Express Bus** operating in Toll lane from Forest Park to the west	TOLL Lane: • I-290 performance improvements • Manage added capacity) • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with TOLL Lane (Bus in Toll Lane) HRT: • Auto diversions to transit • Job access improvement
		**Add lane** from I-88 to Central Ave., **Toll 1 lane** in each direction form I-88 to Racine Avenue, **HRT** to Mannheim Road, and **Express Bus** from Mannheim Rd. to the west	
HOT 3+ & TOLL		**Add HOT 3+ lane** from I-88 to Central Ave., **convert 1 existing lane** in each direction to **HOT 3+ lanes** from Central Ave. to Racine Ave. , **Toll remaining lanes** from I-88 to Racine Ave., and **Express Bus operating in HOT Lane** from Forest Park to the west	HOT Lane & TOLL Lanes: • I-290 performance improvements • Manage existing and added capacity • Regional & job access improvements • Safety improvements Express Bus: • Local travel & job access improvement • Implementable with HOT Lane (Bus in HOT Lane) HRT: • Auto diversions to transit • Job access improvement
		**Add HOT 3+ lane** from I-88 to Central Ave., **convert 1 existing lane** in each direction to **HOT 3+ lanes** from Central Ave. to Racine Ave., **Toll remaining lanes** from I-88 to Racine Ave., **HRT** from Forest Park to Mannheim, and **Express Bus** from Mannheim Rd. to the west	
Value Price & HCT (No Add Lane)		**Value Price all existing lanes** from I-88 to Racine Avenue (maintain existing number of lanes throughout) and extend Blue Line **HRT** to Mannheim Road.	Corridor Advisory Group Suggested Alternative
HOT 3+ & HCT (No Add Lane)		**Convert 1 lane in each direction to HOT 3+** from I-88 to Racine Avenue (maintain existing total number of lanes throughout) and extend Blue Line **HRT** to Mannheim Road.	Corridor Advisory Group Suggested Alternative

6.2 Round 2 Screening Process

As the study process moves forward with detailed evaluations of fewer alternatives, the screening process and measures will be revised & refined as appropriate. For the Round 2 screening process of the 12 combination mode alternatives, a revised evaluation matrix was developed to address 4 out of the 5 principal Purpose and Need points. The evaluation matrix for the combination mode alternatives addressed:

- Improve Regional and Local Travel
- Improve Access to Employment
- Improve Safety for All Users
- Improve Modal Connections and Opportunities



Given the corridor level evaluation and insufficient design detail in Round 2, the Improve Facility Deficiencies need point was not evaluated, but will be considered in Round 3.

The evaluation measures used for **Improve Regional and Local Travel** are those used in Round 1 (and described in Section 3 of this report), except for some consolidation of similar/repetitive measures. This included the removal of I-290 Volume to Capacity (v/c), Average I-290 Speeds, and Arterial v/c measures.

Evaluation measures for **Improve Access to Employment** and **Improve Safety for All Users** are the same as those used in Round 1.

For the **Improve Modal Connections and Opportunities** need point, two additional measures were included: the number of households, and the number of jobs (employment) within 1/2 mile of a transit station, as compared to the No Build or Baseline Alternative.

Evaluation Measures Consolidation

The alternatives scoring system was revised for Round 2. Across each of the 26 measures, alternatives were ranked from 1 to 12 (12 being the best), based on how well they performed relative to the 2040 no build condition. Each alternative was then scored for each need point by the averaging the rankings of all the measures for that need point. A total score for each alternative was then calculated as the sum of the 4 need point scores. With this scoring method, each need point contributes equally to the overall score. The Rank Average for each need point

was summed to arrive at the total, overall score for each alternative. illustrates how the overall scores were calculated.

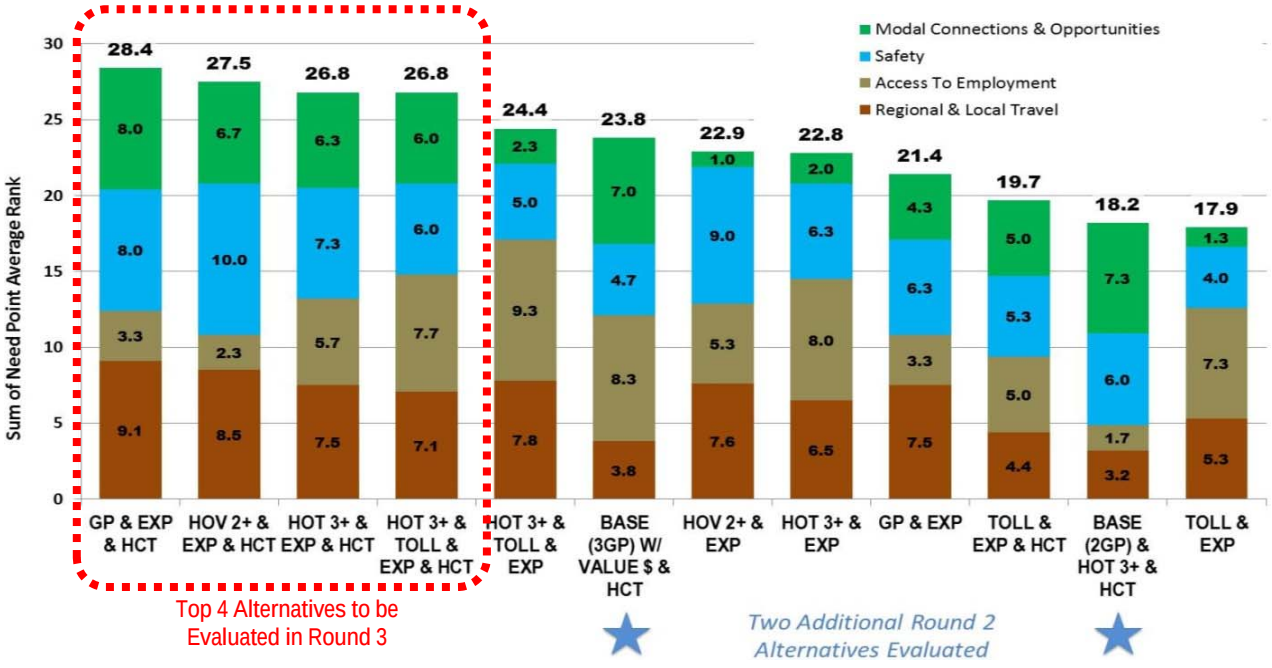


Figure 6-2. Alternative Ranking Example

P&N Point	Rank Average	
	HOV 2+ & EXP	HOV 2+ & EXP & HCT
Improve Regional And Local Travel	7.6	8.5
Improve Access to Employment	5.3	2.3
Improve Safety for All Users	9.0	10.0
Improve Modal Connections & Opportunities	1.0	6.7
Improve Facility Condition and Design	✓	✓
Score = Sum of Rank Averages	22.9	27.5

6.3 Round 2 Screening Results

The overall result of the Round 2 evaluation of the initial combination mode alternatives is presented in Figure 1-6 below. As seen in Figure 6-3, the scores range from a high of 28.4 to a low of 17.9, with the largest gap in scores between the top four and the remaining eight alternatives. The GP & EXP & HCT alternative had the highest overall score of all combination alternatives, followed by the HOV 2+ & EXP & HCT, HOT 3+ & EXP & HCT, and the HOT 3+ & TOLL & EXP & HCT alternative. The total scores for each alternative in this figure are the cumulative result of the individual need point scores.

Figure 6-3. Round 2 Overall Alternatives Ranking

The following summary describes the general effects of adding general purpose or managed lanes to I-290, not adding lanes to I-290, converting existing general purpose lanes to managed lanes, tolling, and transit improvements. It is important to note that the travel demand modeling process is dynamic; travel is being assessed and recalculated over the entire seven county region for each alternative. Depending upon the type of improvements and combination of improvements, the number of trips in the study area may change, trips may shift from one mode to another (i.e., highway to transit), trips may take differing paths, and trip lengths may change. Therefore, each combination alternative yields differing performance results.

General Observations

Adding a Lane to I-290

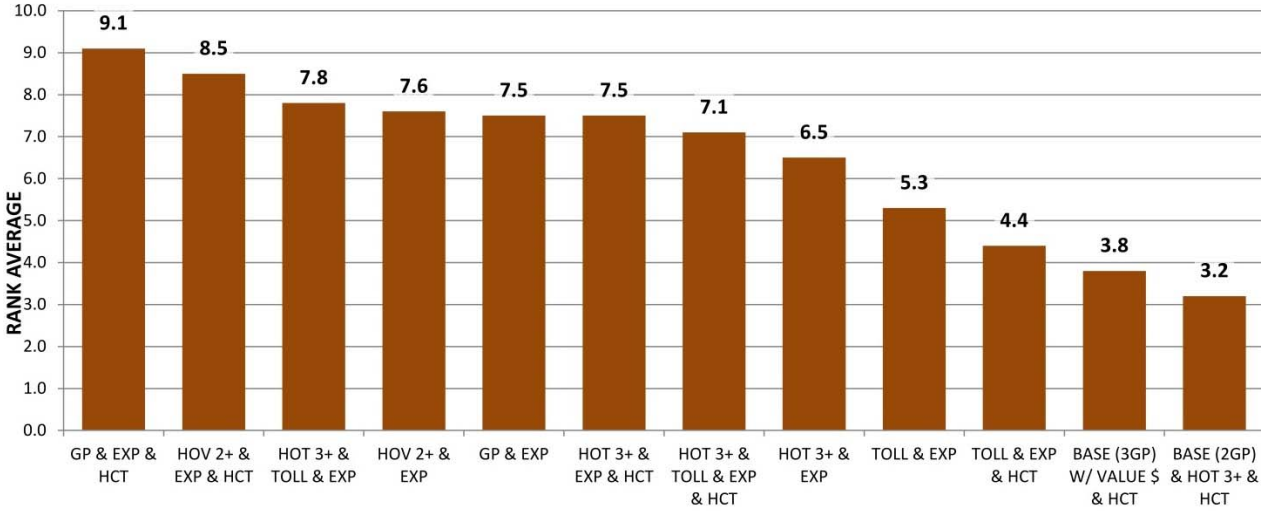
- The top four scoring alternatives include both an additional lane on I-290 between Mannheim Road and Austin Boulevard, and an extension of the CTA Blue Line to Mannheim Road ("HCT") with supporting express and feeder bus services.
  - Adding a lane generally results in **improved travel times** (decrease in Vehicle Hours Traveled, "VHT") on I-290 as well as the arterial system.
  - Adding a lane on I-290 generally results in an **increase in expressway travel** (Vehicle Miles Traveled, "VMT") and a **decrease in arterial travel** (VMT).
  - Adding a *general purpose* lane attracts the most ***traffic*** onto I-290, while adding a *managed lane*, with higher vehicle occupancy rates and/or pricing, allows more ***people*** to travel through the corridor ("daily person throughput").
  - Travel time savings provided by a **tolled managed lane** makes the I-290 corridor relatively more attractive for **longer distance trips**, and consequently, longer distance trips shift onto I-290, and VMT is increased. However, there is a corresponding **decrease in VHT** due to the additional capacity provided.
  - **Tolling**, even with adding a lane to I-290, generally results in **relatively** lower **performance on the arterial system**. Tolling makes I-290 slightly less attractive for shorter trips that would otherwise divert from the arterial system to I-290.
  - Managed lanes shift some trips away from transit because of the added capacity and I-290 travel time improvements.
  - **Managed lanes result in net improvement in travel times in the remaining general purpose lanes.** Existing (and future) carpoolers are drawn to the managed lane and away from the remaining general purpose lanes.

Not Adding a Lane to I-290

- The alternatives that **did not include an additional lane on I-290**, even in combination with a HCT and supporting bus services, **performed relatively poorly**.
  - The lack of an additional lane, coupled with congestion pricing or existing lane conversions that restrict flow on I-290, **causes a significant shift of travel to an already congested arterial system**.
  - Value (congestion) pricing shifts longer distance trips onto I-290 (increased VMT), but congestion pricing, without adding lanes to I-290, also **has a net negative effect upon**

regional and arterial VHT due to the added capacity constraints imposed on the overall system.

Transit Service Expansion



- The alternatives that included HCT and supporting bus services created the relatively **highest number of new transit trips**, but over 50% of the total ridership consists of trips diverted from other existing transit services.
- The alternatives that included HCT and supporting bus services provide **new high capacity options for the reverse commute**.
- The alternatives that included HCT and supporting bus services **generally resulted in increased VMT**, as compared to alternatives without these transit components. This is because the HCT improvements in the study area shift some medium and shorter distance trips from auto and on to transit. This frees up capacity for longer distance trips to shift on to I-290.
- The alternatives that include HCT and supporting bus services provided **slightly better safety performance** as compared to alternatives that did not include HCT, due to the shift in trips to transit (and to I-290), which has a higher safety performance.

The results matrix for the Round 2 evaluation of the 12 combination mode alternatives is provided in Appendix G. The results of the Round 2 screening are summarized below by each principal need point and measure evaluated.

6.3.1 Improve Regional and Local Travel Findings

Seventeen measures were evaluated to arrive at a combined ranking for the Improve Regional and Local Travel need point. As summarized in **Error! Reference source not found.**, when individual measures are combined, the GP & EXP & HCT Alternative is the highest ranked alternative, followed by the HOV 2+ & EXP & HCT Alternative. The BASE (3GP) W/ VALUE $ & HCT and BASE (3GP) & HOT 3 & HCT alternatives were ranked the lowest for this need point. Since Express Bus (EXP) service is included in all alternatives, for simplicity, 'EXP' has been left out of the descriptions in the following discussions.

Figure 6-4. Improve Regional and Local Travel - Round 2 Results

Improve Regional and Local Travel – By Measure:

1.3 I-290 Average Peak Period Travel Time Changes: This measure is divided into two parts: the reduction of time on the general purpose lanes and the reduction of time on the toll, HOT or HOV lane(s). Each alternative reduced the peak travel time on the facility as compared to the 2040 No Build Alternative (average of 17.2 minutes to traverse the study area during peak periods) for both the general purpose lane and for the managed lane, where it existed. The GP+EXP+ HCT (general purpose lane addition) delivered about 8% time reduction. The other HOV2, HOT3, and TOLL alternatives delivered between 9% and 12% time reduction. The HOT3+ & TOLL and BASE (3GP) W/ VALUE $ had 35% to 40% time reductions on I-290, and achieved this result because the value pricing on all existing lanes caused I-290 traffic to divert onto parallel arterials.

1.4 Daily Hours of Congestion on I-290: This measure is divided into two parts: the sum of daily hours of congestion on the general purpose lanes and the sum of daily hours of congestion on the toll, HOT or HOV lane(s). The 2040 No Build has 18 hours of congestion per day on the existing GP lanes. Each alternative reduced the daily hours of congestion, measured as Level of Service "D" or worse during a one hour period of the day. The alternatives that reduced congestion at the highest rate were the BASE (3GP) W/ VALUE $ and the HOT 3+ & TOLL. The reason for this outcome is that the pricing on all lanes caused I-290 traffic to take alternate routes, primarily the parallel arterials.

1.5 Daily Person Throughput: This measure captured the number of persons moving through the study area in a day by auto (SOV, HOV, and HOT) and transit. Each alternative increased the number of persons moving through the corridor over the 2040 No Build Alternative providing increases from about 10,500 to over 40,000 persons. The following contributed to the increase in person throughput in the alternatives:

- The transit alternative used in the scenario – if HCT & EXP was used as opposed to EXP alone, the person throughput increased as travelers switched to transit, and from bus to HCT to make their trip. Also the use of the additional road capacity improved person

throughput in those alternatives by providing additional lanes in the existing 6-lane section.

- Vehicle occupancy – when the opportunity to travel at a higher speed on an HOV or HOT lane is available, some travelers shift from drive-alone to carpool travel to take advantage of the time savings.

1.6 Daily Vehicle Miles of Travel (VMT): This measure is regional in scale and includes both autos and trucks, although autos dominate overall traffic. In all alternatives there is an increase in VMT. In cases where a capacity enhancement is being tested on an important, heavily traveled urban interstate, an increase in VMT is expected. These facilities offering increased capacity and the resulting increased speed entices travelers to take advantage of the new capacity. These travelers may have a similar overall travel time for their trip, but it will actually be a slightly longer trip due to increased speed provided by the facility with the added capacity. Thus, at the regional level, while the miles traveled are slightly higher, it is expected that the total regional time traveled would be lower.

1.7 Daily Vehicle Hours of Travel (VHT): This measure is regional in scale and includes both autos and trucks. There are regional VHT savings for all the alternatives except those where there is no additional capacity increase on I-290. This savings ranges from 1,200 to 28,500 hours saved per day. The alternative with the highest value, 28,500 hours saved is GP & EXP & HCT (general purpose lane). The reason that this alternative achieves this level of VHT savings is that trucks are permitted to use the added capacity, thus reducing hours of travel for all vehicles. The "auto-focused" HOV/HOT alternatives add lanes that do not permit trucks, thus shifting trucks back to the slower general purpose lanes or arterial streets and muting the net change in VHT.

1.8 Congested VMT: This measure is regional in scale, includes autos and trucks, and is reflective of the level of regional congestion change induced by each alternative. All alternatives have a reduction in congested VMT except the BASE (2GP) & HOT 3+ & HCT. The highest reductions occur in the HOT 3+ & TOLL and the GP & EXP & HCT. In analyzing the congested VMT it is important to keep in mind that some capacity additions, such as a general purpose lane, offer shorter less congested routes to both truck and cars – the reason the GP performs well. Others, such as HOT and HOV lane additions, help autos directly since they can use the new lane. Trucks benefit by using the capacity created by the auto diversions. The net regional reduction in congested VMT is often a blend of higher congested VMT in one market and lower in another. For example, this can result in overall relief due to more efficient movement on I-290 offsetting worsening congestion on the arterials parallel to I-290. The alternative HOT 3+ & TOLL, for example, has improved regional congested VMT while worsening I-290 parallel arterial measures. The alternative BASE (2GP) & HOT3+ & HCT retains only 2 General Purpose lanes and converts the third lane to HOT 3+. The constraint on throughput, especially for trucks, is severe, since it is a step down in truck capacity from the 2040 No Build. Accordingly this alternative has slightly more congested VMT than the No Build.

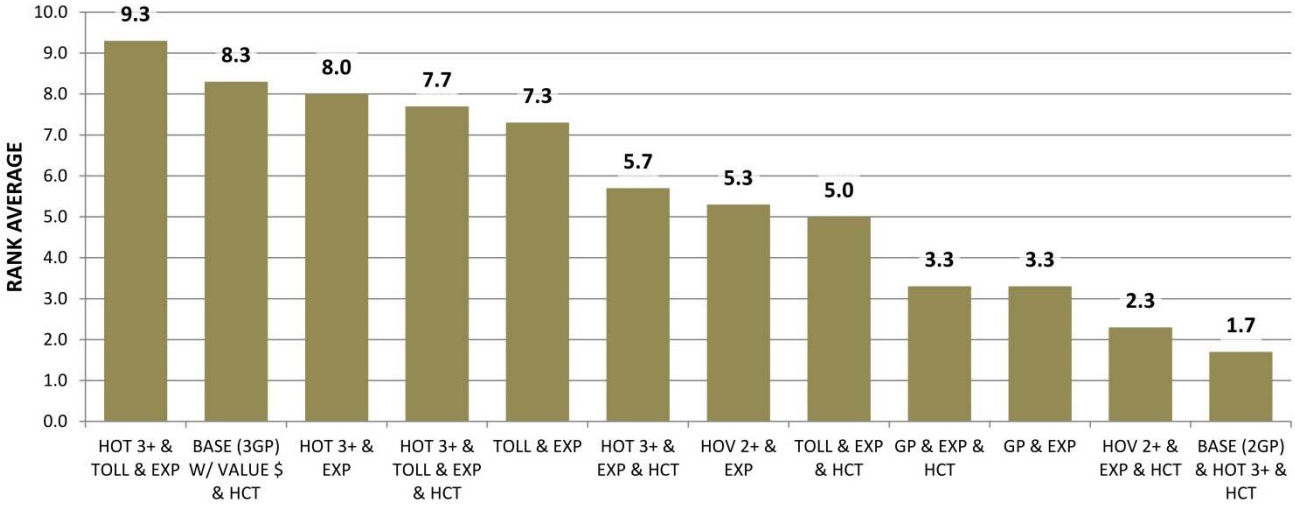
1.9 Hours of Delay: This measure is regional in scale, includes trucks, and should be reflective of the level of delay relief offered by each alternative. All alternatives have a reduction in hours of delay except the BASE (2GP) & HOT 3+ & HCT. The highest reductions occur in the GP & HCT and in the HOT 3+ & TOLL alternatives. Similar to the congested VMT

measure, the alternatives that can offer capacity to trucks as well as autos perform more effectively under this measure. Again the alternative BASE (2GP) & HOT 3+ & HCT which retains only 2 General Purpose lanes and converts the third lane to HOT 3+, shows a counter-intuitive result; hours of delay increase. The reason is that the constraint on throughput, especially for trucks, is severe, since this alternative is a step down in capacity from the 2040 No-Build. Accordingly this alternative has slightly more hours of delay than the No-Build.

1.10 Truck Miles of Travel (TMT): This measure is regional in scale. The results are mixed with most alternatives showing some decrease in TMT. This measure demonstrates that trucks find a more efficient (shorter) distance when provided with the I-290 alternatives. The alternative that does not show a TMT decrease are the GP alternatives. In these alternatives, TMT responds to alternatives that delivers the largest direct increase in truck capacity, which are the GP add lane alternatives. Trucks, on average, travel a bit farther so as to be able to make a faster trip.

1.11 Truck Hours of Travel: This measure is regional in scale. The results are mixed with most showing a decrease in truck VHT. The alternatives showing the greatest truck VHT savings are the GP and the HOT 3+ & TOLL. The GP alternative as mentioned above, delivers the largest direct increase in truck capacity, thus decreasing regional truck hours. The HOT 3+ & TOLL & EXP which has three tolled lanes all admitting trucks that are willing to pay toll, gets the biggest decrease in trucks hours. This savings is achieved by the parallel arterials carrying the extra truck traffic.

1.12 Congested TMT: This measure is regional in scale, addresses trucks only, and is reflective of the level of congestion relief offered by each alternative to trucks. All alternatives have a very small reduction in congested Truck Miles Traveled with the exception of BASE (2GP) & HOT 3+ & HCT. The alternatives with the greatest congested TMT savings are the GP and the HOT 3+ & TOLL; the reason for the reduction in TMT is that those alternatives have added lanes that allow trucks. The exception cited above is due to a constraint on throughput, especially for trucks, since this alternative is a step down in capacity from the 2040 No-Build since trucks may not use the HOT lane. Accordingly this exception alternative has slightly more congested Truck Miles Traveled than the No Build.



1.13 Truck Hours of Delay: This measure is regional in scale, addresses trucks only, and should be reflective of the level of delay relief offered by each alternative to trucks. All alternatives have a reduction in truck hours of delay. The alternative with the greatest truck hours of delay savings is GP & HCT because the added capacity of this alternative permits trucks, and the addition of HCT induces some mode shift to transit resulting in more available capacity for trucks.

6.3.2 Improve Access to Employment Findings

The overall results of the Round 2 combination mode alternatives evaluation for the Improve Access to Employment need point are presented in Figure 6-5. Three measures were evaluated to arrive at a combined ranking for this need point. As summarized in , when individual measures are combined, the HOT 3+ & TOLL alternative is the best performing, for access across all modes, followed by the BASE (3GP) W/ VALUE $ & HCT and the HOT 3+ alternatives. The HOV 2+ and BASE (3GP) & HOT 3+ & HCT alternatives were ranked the

lowest for this need point as a result of poorer performance in access to jobs by auto as compared to the other alternatives.

Figure 6-5. Round 2 Improve Access to Employment Results

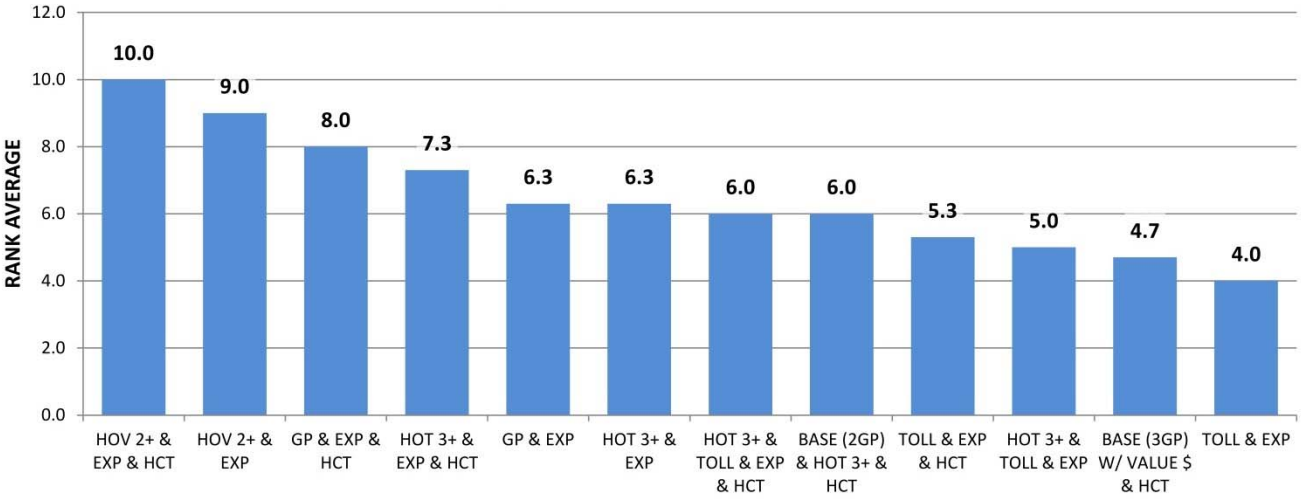
Improve Access to Employment – By Measure:

2.1 # of Jobs Accessible within 60 Minutes (Auto): 8 of the 12 alternatives show an increase in the number of jobs accessible within 60 minutes by auto. The key factor in this measure is travel speed; the faster the overall trip travel speed, the greater the area (and number of jobs) can be reached within 60 minutes. The auto accessibility scores generally follow the speed improvements on the I-290 facility. The exceptions are those alternatives such as HOV 2+ where the improvements are provided to a subset of commuters – carpoolers instead of to all drivers. Those alternatives that reduce traffic or manage added capacity on I-290 also get resulting increased speeds, making more employment sites accessible within 60 minutes.

HOT 3+ & TOLL alternatives generally show the greatest improvement compared to the 2040 No Build Alternative. This is primarily due to the indicating the greatest travel time improvement on I-290 that tolls provide by managing added capacity and diverting varying amounts of I-290 traffic to other routes including parallel arterials. The decreased travel time results in more jobs being accessible to the study area via I-290 in the same amount of time. Also, due to higher travel speeds in the HOT 3+ lanes, users of the HOT 3+ lanes have access to greater number of jobs in the same amount of time. The TOLL and HOT 3+ alternatives showed the next best improvement in I-290 average travel time.

2.2 # of Jobs Accessible within 60 Minutes (Transit): All alternatives return an increase in jobs within 60 minutes by transit. The set of two transit scenarios, EXP and EXP & HCT return a fixed increase in transit accessibility across all alternatives because the transit improvement scenarios assumed are the same for EXP and EXP & HCT.

With respect to transit accessibility to jobs, alternatives with only EXP showed slightly greater accessibility to jobs than the EXP & HCT alternatives as compared to the 2040 No Build Alternative. This is primarily due to the bus to HCT transfer location between HCT and EXP alternatives. For the EXP alternatives, the transfer takes place at the existing



Forest Park terminal station of the CTA Blue Line. For the EXP & HCT alternatives, this transfer takes place at a terminal near Mannheim Road, several miles west of the Forest Park Terminal. Transfers between EXP and HCT that take place further to the west are subject to three additional stops along the HCT alignment, versus an express bus ride to Forest Park station. These additional stops increase the travel time slightly, resulting in fewer jobs accessible in 60 minutes.

2.3 # of Jobs Accessible within 60 Minutes (Transit & Auto): All alternatives return an increase in jobs within 60 minutes using the sum of auto and transit with the defining input being the auto portion. The alternatives with very high speed reductions on I-290 rated highest for this measure.

6.3.3 Improve Safety for All Users Findings

The overall results of the evaluation of the Round 2 combination mode alternatives for the Improve Safety for All Users need point are presented in Figure 6-6. In Round 2, the primary variables used to evaluate the relative safety performance between alternatives are traffic volumes and person throughput. Three measures were evaluated to arrive at a combined safety ranking. As summarized in , when individual measures are combined, the HOV 2+ & HCT Alternative is the best performing, followed by the HOV 2+, the GP & HCT, and the HOT 3+ & HCT alternatives. The TOLL and the BASE (3GP) W/ VALUE $ alternatives were ranked the lowest for this need point, relative to each alternatives performance against the no-build condition.

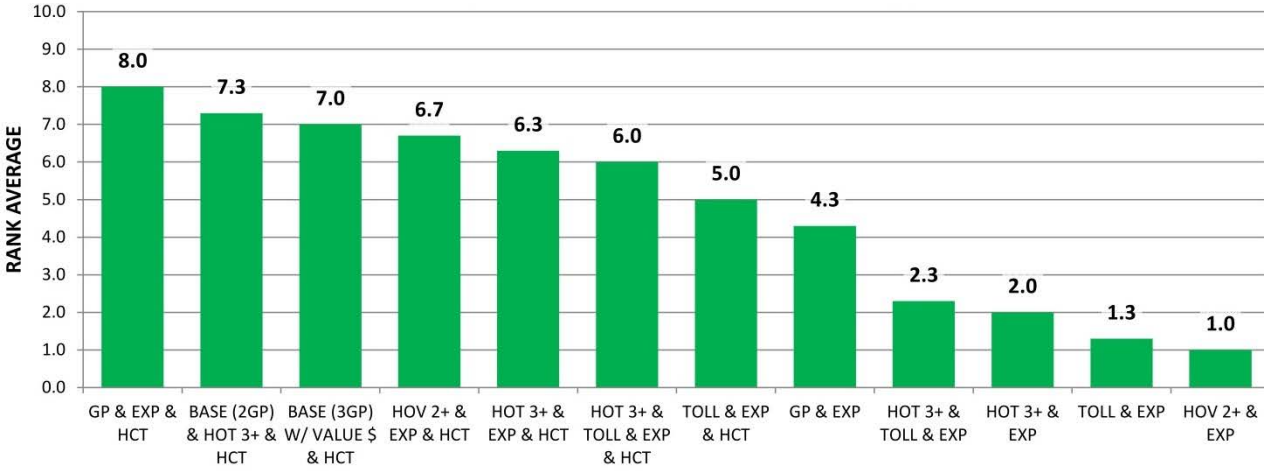
Figure 6-6. Round 2 Improve Safety for All Users Results

As alternatives are better defined in subsequent evaluations, additional design variables will be incorporated.

Improve Safety for All Users – By Measure:

3.1 Arterial Safety: GP & HCT and HOV 2+ & HCT show the most improvement in arterial injury and fatal crash rates as compared to the 2040 No Build Alternative because these alternatives indicate the largest decreases in volumes along the study area arterials. Larger the declines in study area arterial volumes results in better improvement in the injury and

fatality vehicle crash rate since arterials have a higher baseline rate of injuries and fatalities as compared to expressways. Conversely, any alternative that applied a toll to the mainline either one lane or all lanes indicated a decrease in safety as compared to the 2040 No Build due to the these alternatives experiencing a relative increase in traffic volumes on study area arterials. The worst performing alternative with respect to arterial safety is the BASE w/ VALUE $ that tolls all existing lanes and does not add any additional capacity to I-290.



3.2 **Expressway Safety**: For safety related to the I-290 expressway in the study area, the BASE w/ VALUE $ alternatives showed the greatest improvement in safety performance as compared to the 2040 No Build Alternative primarily due to the most study area expressway volume reduction of all alternatives, resulting in relatively less exposure to potential for crashes. Also, the addition of a fourth lane in each direction also has improved safety characteristics as it conveys the expressway volumes more effectively than three lanes. Of the 12 combination mode alternatives evaluated, alternatives without a High Capacity Transit extension show slightly better expressway safety performance than their non-HCT extension counterpart. In all cases, the addition of HCT results in a slight increase in traffic volumes on I-290 as compared to the same alternative without the HCT. This is primarily due to a change in trip distribution with HCT, making I-290 more attractive for longer, regional trips and HCT more attractive for trips starting or ending in the study area. The higher traffic volumes result in slightly decreased predicted expressway safety performance in HCT alternatives compared to their non-HCT counterpart (Appendix G summary matrix, measure 3.2).

3.3 **Overall Safety**: Overall alternative safety performance considers the arterial, expressway, and transit systems in the study area, based on person miles traveled rather than vehicle miles traveled. This measure evaluates crash rate with respect to person throughput via transit and auto (assuming that there are no injuries or fatalities for transit users). The calculated annual injury and fatalities for the expressway and arterials was totaled, then divided by the number of individual person miles traveled by auto (including multiple passenger cars) and on transit (bus & rail) through the study area. Based on crash rates per person miles traveled, the HOV 2+ & HCT alternatives indicate the highest safety improvement as compared to the 2040 No Build alternative, followed by the HOV 2+ and GP & HCT alternatives. This is due to the more balanced safety improvements between the arterials and expressway by these alternatives (as opposed to the BASE (3GP) W/ VALUE $ & HCT and TOLL alternatives) and the generally higher vehicle occupancy of these alternatives. Also, of the five combination mode alternative pairs with and without an HCT extension, alternatives with an HCT extension show slightly better overall safety improvements. This is due to a relatively higher person throughput in the corridor for those alternatives with an HCT extension as compared to those without (see measure 1.5).

6.3.4 Improve Modal Connections and Opportunities Findings

The overall results of the evaluation of the Round 2 combination mode alternatives for the Improve Modal Connections and Opportunities need point are presented in . Three measures were evaluated to arrive at a combined ranking for this need point. As summarized in , when individual measures are combined, the GP & HCT alternative is the best performing, followed by the BASE (2GP) & HOT 3+ & HCT alternative. The TOLL and HOV 2+ alternatives were ranked the lowest for this need point.

Figure 6-7. Round 2 Improve Modal Connections and Opportunities Results

Improve Modal Connections and Opportunities – By Measures:

4.1 – New Transit Trips: While a High Capacity Transit extension and Express Bus Service generally improve transit service in the corridor, all but one alternative results in a slight reduction of regional transit trips as compared to the 2040 baseline condition. The GP alternatives showed the best transit performance, with the GP & EXP & HCT Alternative resulting in an increase of 1,300 transit trips, and the remaining alternatives all showing decreases in transit trips as compared to the 2040 No Build Alternative. The GP alternatives are more compatible with transit, whereas the managed lane alternatives such as HOT, HOV, an even tolling an value pricing, all compete with transit resulting in a net decrease in regional transit ridership. However, from a physical and operational perspective, the HOV, HOT, and Tolling options provide a managed lane for express bus operations, rather than relying on shoulder riding in the GP alternatives.

When comparing an alternative with an HCT extension with its counterpart without an HCT extension, transit trips are greater. This is due to HCT providing a higher level of transit service than express bus, with decreased headways and higher running speeds.

4.2.1 & 4.2.2 – Access to Transit within 0.5 Mile for Household and Employment: The transit assumptions for transit service location is identical across all alternatives with or without a High Capacity Transit Extension. Therefore, each alternative with an HCT extension achieves the same number of additional households and employment within a half-mile of a station, as does each alternative without the HCT extension.

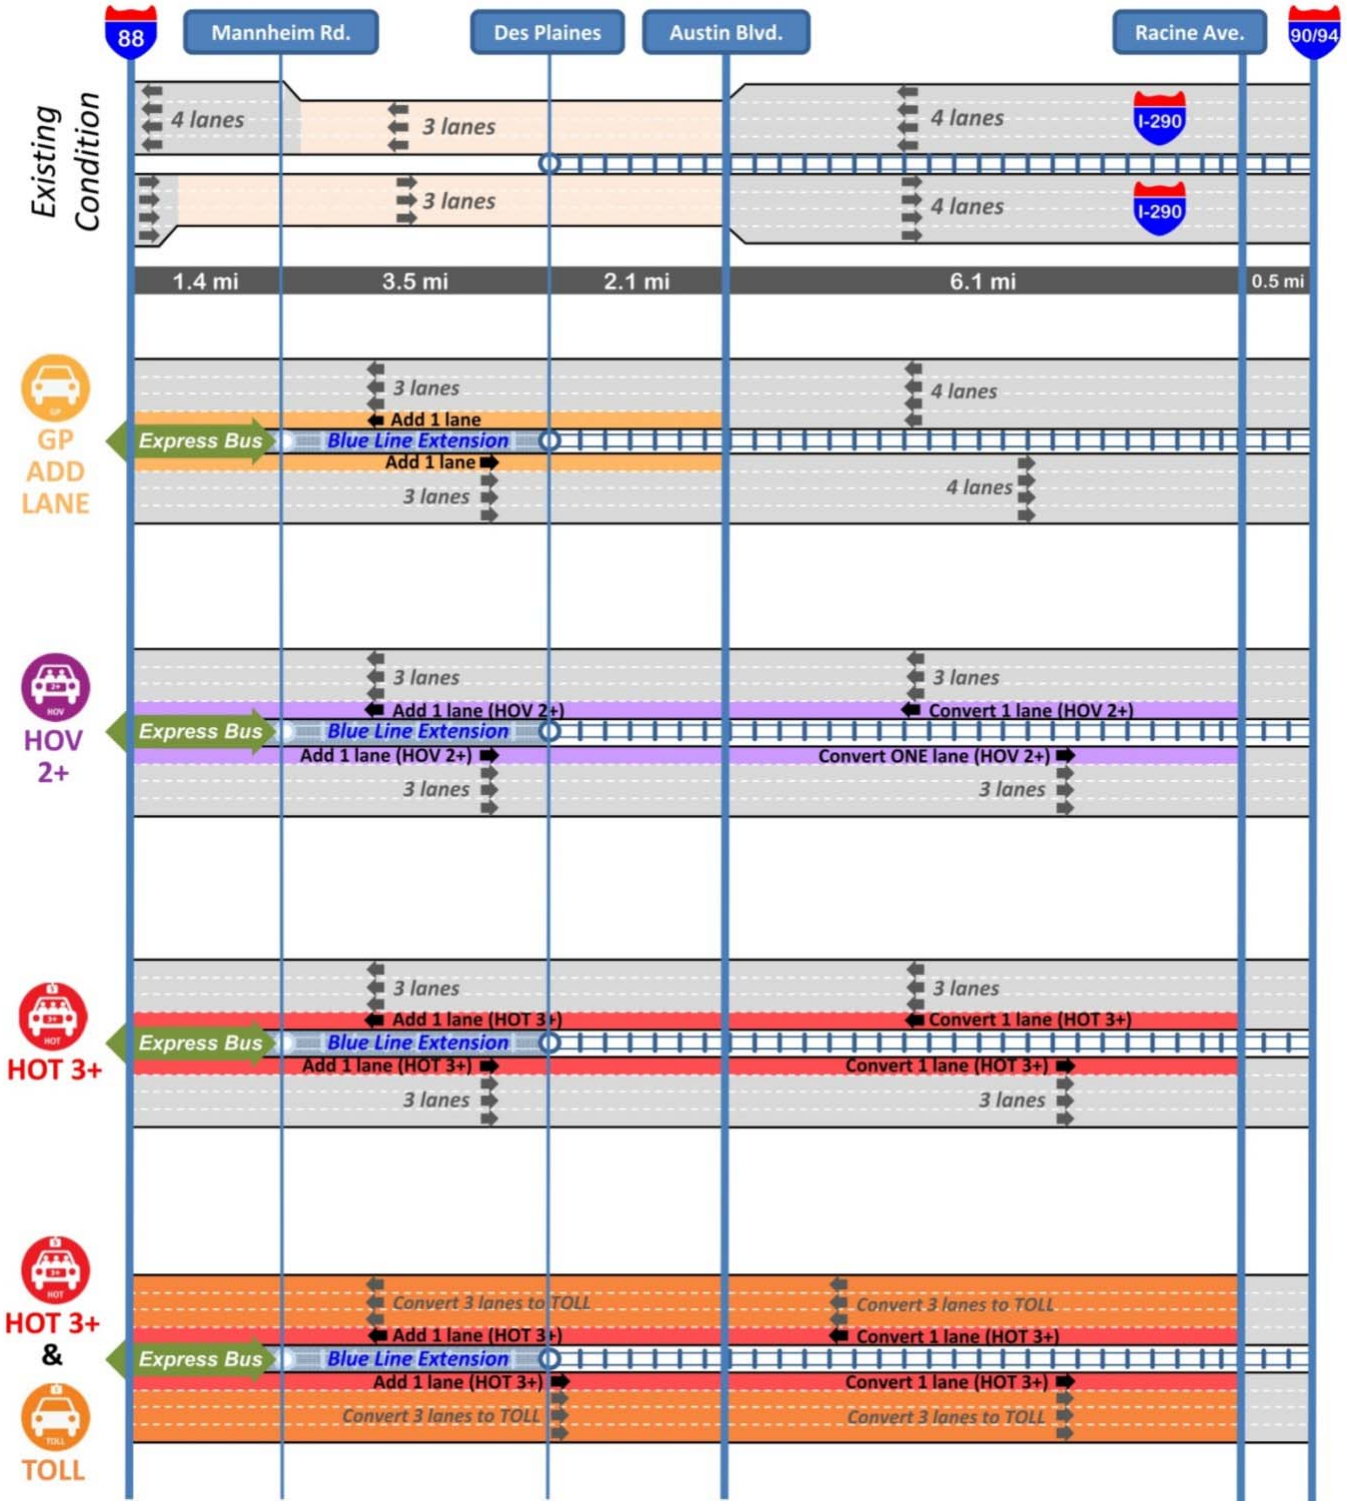
6.3.5 Alternatives to be Evaluated in Round 3

Based on the results of the Round 2 evaluation, four alternatives are being advanced for further evaluation in Round 3.

Figure 6-8 summarized the four alternatives. These four were selected because they were the overall top performers that had the overall highest scores. A logical cutoff exists between the fourth and fifth ranked alternative, where the largest scoring gap between two successively ranked alternatives exists.

Overall/Combined Performance – Top Four Alternatives

As noted above, the top four alternatives scored relatively higher than the other eight alternatives that were considered in Round 2. The following is a description of the combined performance, including all four need points, for each of the top four alternatives.



- The GP & HCT alternative provides the best overall score of 28.4, driven by having the highest regional and local travel and modal connections and opportunity improvements, as well as providing good safety performance. The added capacity attracts longer distance trips from the arterial network and onto the expressways for which they are intended. This shift from arterials also improves arterial performance in the study area, giving GP lanes the relatively highest overall performance for improving regional and local travel. The GP lane combination alternatives showed a lower accessibility to jobs and safety performance compared to other alternatives. Accessibility to jobs for the GP Lane combination alternatives is improved over the baseline condition, but not to the same extent as the managed lane alternatives. This is due to the managed lanes providing a faster path than the GP Lanes, allowing users of the managed lanes to access more jobs located further away in 60 minutes or less. With respect to safety, GP Lane combination mode alternatives provide more vehicle throughput than the managed lane combination mode alternatives. This increased throughput slightly increases the potential for crashes relative to the managed lane combination mode alternatives.
- The HOV 2+ & HCT alternative scored second best overall at 27.5, and provided the best safety performance, and the second highest improvements to local and regional travel, as well as ranking as one of the top three for modal connections and opportunities. HOV lanes provided as much as a 40% reduction in daily hours of congestion in the managed lane, and over 11% in the general purpose lanes. This is due in part to the already high percentage of HOV 2+ vehicles in this corridor that could use the HOV 2+ lane. The HOV 2+ combination alternatives indicated the highest safety performance improvements due to the combination of increased expressway traffic volume and increased person throughput.
- The two HOT 3+ combination mode alternatives (with and without TOLL) showed good overall performance with two HOT 3+ combination mode alternatives in the top 4 overall performers. The two HOT 3+ alternatives in the top four both scored the same overall, with a need point rank sum of 26.8. The two HOT 3+ alternatives, reflected the highest performance related to access to employment due to HOT 3+ use restrictions that better manage operations that results in a relatively faster route (as compared to other combination alternatives) to jobs from the study area. The HOT 3+ & TOLL induces further reduction in demand along I-290, resulting in additional travel time savings that translate into more jobs accessible in 60 minutes. Safety performance in these alternatives was generally better compared to other combination alternatives due to relatively lower traffic volumes (less risk of crashes) and higher person throughput. It should be noted that

conversion of existing non-tolled GP interstate lanes to HOT or Toll lanes is currently restricted legislatively, although there are federal programs that allow conversion of HOV lanes to HOT lanes, and the conversion of GP lanes to value pricing.

Identification of Combination Modes for Evaluation in Round 3 (DEIS Alternatives):

The results from the Round 2 combination mode evaluation establish the set of alternatives for further evaluation in Round 3 in the DEIS. As noted above, the top four alternatives overall scores were relatively higher than the remaining eight alternatives, and as such, the top four alternatives, shown in Figure 6-8, will be carried into Round 3 for further evaluation. The proposed Round 3 DEIS alternatives will be refined to improve their performance with respect to each need point, with access to employment being a particular focus. Additional engineering detail will be added to these alternatives, which will allow for an expansion of the evaluation criteria, including social, economic, environmental and cost factors. As shown in Figure 6-8, the following four alternatives are being advanced into Round 3:, GP & EXP & HCT, HOV 2+ & EXP & HCT, HOT 3+ & EXP & HCT, and HOT 3+ & TOLL & EXP & HCT. These alternatives will be further refined and evaluated in Round 3 for the expanded study area from I-88 to Racine Avenue.

Figure 6-8. Four Alternatives to be Evaluated in Round 3

Alternatives Identification and Evaluation Report

November 2011

APPENDIX A

Initial Alternatives Identification & Pre-Screening

Draft

1. Overview of Design Concepts and Pre-Screening Results

Over 570 suggestions were submitted by project stakeholders on how to address the Purpose and Need of the I-290 project. As part of the pre-screening process, the suggestions were sorted into three main groups: roadway improvements, transit improvements, and related improvements that could be combined with other concepts. Based on the stakeholder suggestions, each of the three groups was expanded to include distinct categories of concepts (example: add general purpose lanes to I-290). After reviewing the comments and suggestions from stakeholders, 33 concept categories emerged to which each suggestion or comment was assigned. A pre-screening of the 33 concept categories was performed to determine the concepts that would be carried forward into Round 1, not carried forward for further consideration, or deferred to a future round of evaluation. Table 1-1 summarizes the results of the pre-screening process. The sections that follow provide the general functional description of each concept and the pre-screening finding.

Table 1-1. Summary of Pre-Screening Findings

Concept Categories	Concept Disposition		
	Carried Forward	Not Carried Forward	Deferred to Subsequent Rounds
Roadway Improvements			
A1. Add general purpose lanes to I-290	✓		
A2. Add a high-occupancy vehicle (HOV) lanes to I-290	✓		
A3. Add a high-occupancy toll (HOT) lane in each direction	✓		
A4. Toll I-290 lanes	✓		
A5. Arterial Widening	✓		
Transit Improvements			
B1. Extend CTA Blue Line to O'Hare Airport		✓	
B2. Extend CTA Blue Line west	✓		
B3. Extend CTA Blue Line west via Illinois Prairie Path	✓		
B4. Add CTA Blue Line express service			✓
B5. Extend CTA Green Line to Maywood		✓	
B6. Add BRT via Prairie Path	✓		
B7. Add BRT along I-290	✓		
B8. Add BRT along east-west arterials		✓	
B9. Improve existing commuter rail		✓	
B10. New commuter rail service		✓	
B11. Convert the existing CTA Blue Line to BRT	✓		
B12. Remove the existing CTA Blue Line		✓	

Concept Categories	Concept Disposition		
	Carried Forward	Not Carried Forward	Deferred to Subsequent Rounds
B13. Add High Speed Rail		✓	
B14. Add Inner Circumferential Commuter Rail		✓	
B15. Express Bus	✓		
B16. Add Automated Guideway Transit		✓	
B17. Add Light Rail Transit		✓	
Related Improvements (that can be combined with other concepts)			
C1. Add express bus service within the project area			✓
C2. Interchange improvements and design			✓
C3. Improve non-motorized facilities			✓
C4. Improve transit stations			✓
C5. Improve transit operations/connections			✓
C6. Add Transportation System Management /Active Traffic Management/Intelligent Transportation Systems			✓
C7. Add a cap over the expressway			✓
C8. Double-deck I-290		✓	
C9. CTA Blue Line in Subway/Tunnel or Elevated			✓
C10. Arterial Improvements			✓
C11. Other			✓
Pre Screening Category Totals	11	11	11

DRAFT

A Roadway Improvements

A1. Add general purpose lanes to I-290

General Functional Description

This concept would add capacity to I-290 as general purpose travel lanes. This category includes concepts with additions of one or more lanes in each direction along I-290.

Pre-Screen Finding: *CARRIED FORWARD*

A single add lane concept is being carried forward for evaluation in Round 1 screening evaluation because adding capacity along I-290 would serve the identified east-west travel market and improve facility conditions in the project area. Adding one lane in each direction through the study area was carried forward for evaluation since it would provide a consistent eight-lane section between I-88 and downtown Chicago. Due to right-of-way (ROW) constraints in this urban corridor, a 10-lane section was not carried forward into Round 1. A map representing this concept is provided in Appendix C.

- [GP LANE] General Purpose Add Lane From I-88 to Central Avenue along I-290 (Add 4th lane each direction)

A2. Add high-occupancy vehicle (HOV) lanes to I-290

General Functional Description

High Occupancy Vehicle (HOV) lanes restrict the use of a travel lane to vehicles that meet the required occupancy requirements (typically two or more people per vehicle including the driver). This category includes all concepts that add HOV lanes to I-290 in the study area with either 2+ or 3+ configurations and several beginning- and end-point suggestions.

Pre-Screen Finding: *CARRIED FORWARD*

Six different variations of the HOV concept are being carried forward into the Round 1 screening process to capture several different termini and operating parameters. Maps representing these alternatives are also shown in Appendix C.

- [HOV 2L] HOV 2+ From I-88 to Racine Avenue along I-290
- [HOV 2W] HOV 2+ From Oak Brook (IL 83) along I-88 and I-290 to Central Avenue
- [HOV 2LL] HOV 2+ Oak Brook (IL 83) along I-88 and I-290 to Racine Avenue
- [HOV 3L] HOV 3+ I-88 to Racine Avenue
- [HOV 3W] HOV 3+ Oak Brook (IL 83) along I-88 and I-290 to Central Avenue
- [HOV 3LL] HOV 3+ Oak Brook (IL 83) along I-88 and I-290 to Racine Avenue

DRAFT

A3. Add a high-occupancy toll (HOT) lane in each direction

General Functional Description

HOT lanes allow higher occupant vehicles to access a toll lane without paying a toll, while all other vehicles using the HOT lane are required to pay a toll. This concept adds HOT lanes along I-290.

Pre-Screen Finding: *CARRIED FORWARD*

This concept is being carried forward to the Round 1 screening for further evaluation, with 3+ person vehicles allowed to use the HOT lane without paying a toll, and all other vehicles paying a toll to use the HOT lane. Two variations on termini will be evaluated to identify the effects of the different termini. Maps representing these alternatives are provided in Appendix C:

- [HOT 1] HOT 3+ from Oak Brook (IL 83) along I-88 and I-290 to Central Avenue ($1.00 Toll for 11 miles)
- [HOT 2] HOT 3+ from Oak Brook (IL 83) along I-88 and I-290 to Racine Avenue ($1.50 Toll for 16.5 miles)

A4. Tolling of I-290

General Functional Description

Tolling concepts include flat or variable tolling of all vehicles in existing lanes and/or new lanes along I-290 in the study area. Variable tolling changes the cost of travel depending on the time of day or the level of congestion on the roadway. A flat toll keeps the cost of travel the same, regardless of the time of day.

Pre-Screen Finding: *CARRIED FORWARD*

Two tolling concepts are being carried forward for evaluation in Round 1. The two variations on tolling include tolling the existing lanes only, and adding an additional lane in each direction and tolling all lanes. Maps representing these alternatives are provided in Appendix C:

- [TOLL 1] Toll Existing I-290 Lanes from I-88 to Cicero Avenue
- [TOLL 2] Toll I-290 with an Add Lane in each direction between I-88 and Cicero Avenue

DRAFT

A5. Arterial Widening

General Functional Description

This concept would expand Roosevelt Road and Madison Avenue to four continuous through lanes (2 lanes each direction). Roosevelt Road would be expanded between I-294 and Cicero Avenue; Madison Avenue would be expanded between 25th Avenue and Cicero Avenue.

Pre-Screen Finding: *CARRIED FORWARD*

This concept is being carried forward into the Round 1 evaluation

- [ART 1 & 2] Widening of Roosevelt Road and Madison Avenue to 4 continuous through lanes (2 lanes each direction). Roosevelt Road from I-294 to Cicero Avenue and Madison Avenue from 25th Avenue to Cicero Avenue.

DRAFT

B Transit Improvements

B1. Extend CTA Blue Line to O'Hare Airport

General Functional Description

This concept would extend the existing Chicago Transit Authority (CTA) Blue Line to O'Hare airport from the existing CTA Forest Park station. The extension would follow the Canadian National (CN) railroad line and create a Blue Line loop.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not carried forward for further consideration in the I-290 Study because it would not serve the identified east-west travel market.

B2. Extend CTA Blue Line west

General Functional Description

This category includes concepts that would extend the CTA Blue Line from the existing Forest Park station to points further west of Forest Park along I-290. This sub-category includes all suggestions to extend the Blue Line along I-290. These concepts also include enhancements to existing local bus service to provide feeder service to the proposed new CTA stations and park-and-ride sites for the new stations.

Several distinct termini locations for a Blue Line extension from the Forest Park CTA terminal were suggested, which are shown in Appendix C.

Pre-Screen Finding: *CARRIED FORWARD*

Two versions of the Blue Line extension are being carried forward into the Round 1 evaluation because they extend existing high capacity transit service and serve the identified east-west traditional and reverse commute travel markets in this corridor. Two of the five versions of Blue Line extension are being carried forward into Round 1 to evaluate performance sensitivity related to extension length. Maps representing these alternatives are provided in Appendix C:

- [HRT 2] Blue Line extension from Forest Park to Oak Brook (IL 83) in the I-290 median (at grade), and parallel to I-88 (elevated)
- [HRT 3] Blue Line extension from Forest Park to Mannheim in the I-290 median (at grade)

DRAFT

B3. Extend CTA Blue Line west via Illinois Prairie Path

General Functional Description

This category includes concepts that would extend the CTA Blue Line west from the existing Forest Park station to points west using the existing Illinois Prairie Path alignment. The concepts include enhancements to existing local bus service to provide feeder service to the new CTA stations.

Stakeholders suggested several different variations of the Blue Line extension via Illinois Prairie Path, which are shown in the Appendix C.

Pre-Screen Finding: *CARRIED FORWARD*

A Blue Line extension via Illinois Prairie Path is being carried forward for evaluation in Round 1 because this would extend high capacity transit service and serve the identified east-west traditional and reverse commute travel markets in this corridor. Maps representing these alternatives are provided in Appendix C:

- [HRT 1] Blue Line extension along the Illinois Prairie Path, Butterfield Road, and 22nd Street (elevated) from Forest Park to Oak Brook (IL 83)

B4. Add CTA Blue Line express service

General Functional Description

This concept would add new express rapid transit service along the existing Blue Line between downtown Chicago and western portions of the study area with limited stops in between.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in future evaluations.

B5. Extend CTA Green Line to Maywood

General Functional Description

This concept would extend the CTA Green Line to Maywood along the Union Pacific west rail line.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration because it would duplicate existing Metra UP-W service that serves Maywood and it would not directly address the need to serve the identified east-west travel market along the I-290 corridor.

B6. Add BRT via Prairie Path

General Functional Description

This concept would create a dedicated bus rapid transit (BRT) facility along the Illinois Prairie Path (IPP) to points further west. The BRT system would connect the Forest Park CTA Terminal to Oakbrook following IPP and Butterfield Road.

Pre-Screen Finding: *CARRIED FORWARD*

This concept is being carried forward to the Round 1 evaluation because it would serve the identified east-west traditional and reverse commute travel markets in this corridor. The concept includes enhancements to existing local bus service to provide feeder service to the proposed new CTA BRT stations. A map representing this alternative is provided in Appendix C:

- [BRT 1] Oak Brook to Forest Park CTA Terminal - via Butterfield Road and IL Prairie Path

B7. Add BRT along I-290

General Functional Description

This concept group includes suggestions to create a dedicated bus rapid transit (BRT) facility along I-290. The BRT would connect the Forest Park CTA Terminal to points west following I-290. This sub-category also includes suggestions from the Cook-DuPage Corridor Study (e.g. the J-line).

Pre-Screen Finding: *CARRIED FORWARD*

Three BRT concepts were carried forward into the Round 1 evaluation because this transit mode serves the identified east-west traditional and reverse commute travel markets in this corridor. Three variations of BRT via I-290 are being carried forward for initial single mode evaluation in Round 1. These concepts include enhancements to existing local bus service to provide feeder service to new BRT stations. Maps representing these alternatives are provided in Appendix C:

- [BRT 2] Oak Brook to Forest Park CTA Terminal – parallel to I-88 (elevated) and I-290 median (at-grade)
- [BRT 3] Oak Brook to Cicero Avenue – Parallel to I-88 (elevated) and I-290 median (at-grade)
- [BRT 5] Lombard to Forest Park CTA Terminal – parallel to I-88 (elevated) and along I-290 median (at-grade)

DRAFT

B8. Add BRT along east-west arterials

General Functional Description

This concept adds bus rapid transit (BRT) service to east-west arterials in the study area.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward since arterial BRT has already been included in the background bus improvements assumed for the 2040 travel demand model.

B9. Existing Commuter Rail Improvements

General Function Description

This category includes concepts for station improvements, station consolidation, and additional capacity improvements along the existing commuter rail lines in the study area.

Pre-Screen Findings: *NOT CARRIED FORWARD*

These concepts are not being carried forward in the I-290 study since the majority of the commuter rail improvements are included as committed projects and are in the 2040 baseline network, or are being studied by Metra as part of their UP-West Line Alternative Analysis study.

B10. New Commuter Rail Service

General Function Description

This concept includes a new commuter rail line within the I-290 corridor, along either the CN and CSX rights-of-way.

Pre-Screen Findings: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration in the I-290 Study because it would not serve the identified east-west travel market in the case of the CN routing, and because it duplicates service already provided by the CTA Blue Line in the case of the CSX routing. Also, several other existing proposals by area transit providers, including the Inner Circumferential Commuter Rail and the Mid-City Transitway, would connect O'Hare and Midway airports (see Section B14 of this document).

DRAFT

B11. Convert the existing CTA Blue line to BRT and extend to west

General Functional Description

This concept would convert the existing CTA Blue Line between the Ashland Avenue CTA station and Forest Park CTA station with BRT service and would extend BRT service west of the Forest Park station along the I-290 corridor.

Pre-Screen Finding: *CARRIED FORWARD*

The concept to convert the existing Blue Line to BRT and extend to the west is being carried forward to the Round 1 screening for further evaluation. A map representing this alternative is provided in Appendix C:

- [BRT 4] Oak Brook to Ashland Avenue – parallel to I-88 (elevated) along I-290 median (at-grade), convert existing CTA ROW to BRT from Forest Park to Ashland Avenue.

B12. Remove the existing Blue line

General Functional Description

This concept would remove the existing CTA Blue Line to the west of the medical center (Ashland Avenue) and build a new transfer station for Illinois Medical District (IMD) and access to yard and shop at 54th Street.

Pre-Screen Finding: *NOT CARRIED FORWARD*

The concept to remove the Blue Line without replacement of any other transit service is not being carried forward because it would remove existing service to east-west transit markets.

B13. Add High Speed Rail

General Functional Description

This concept would add high-speed commuter rail to the I-290 corridor. High speed rail is generally defined to be commuter rail service that runs on grade-separated ROW connecting long-distance destinations at speeds in excess of 100 mph.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration because high-speed rail is intended to serve long distance inter-city travel markets, and is not suited for this corridor and the identified urban/suburban markets the project needs to serve.

B14. Add Inner Circumferential Commuter Rail

General Functional Description

The Inner Circumferential Rail Line (ICR) would provide commuter rail service along the Indiana Harbor Belt Line Railway from O'Hare airport to Midway airport.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration in the I-290 Study because ICR proposal focuses on providing service for the north-south travel markets of O'Hare and Midway airport, and would not serve the identified east-west travel market along the I-290 corridor. A feasibility study has been completed for this concept, and the project is listed in the CMAP Go To 2040 regional plan, but is not included as a financially-constrained project.

B15. Express Bus

General Functional Description

This concept includes various express bus services in the study area, along I-290 from DuPage and northwest Cook counties to and from the Forest Park CTA terminal. Buses would run on the I-290 shoulder, in existing lanes, or in a managed lane.

Pre-Screen Finding: *CONSIDERED*

An express bus concept is being carried forward to the Round 1 screening for further evaluation because it would serve the identified east-west traditional and reverse commute travel markets in this corridor and is compatible with existing transportation services. A map representing this alternative is provided in Appendix C:

- [EXP] Express Bus to Forest Park CTA

B16. Add Automated Guideway Transit

General Functional Description

This concept would add an automated guideway transit (AGT) within the I-290 project area. AGT is an automated (driverless) transit system that runs on a fixed guideway.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration because AGT primarily serves as circulator and distributor of travelers and it generally has very closely-spaced stations. It does not provide commuter service with station spacing of one mile or more.

B17. Add Light Rail Transit

General Functional Description

This concept would add a light rail transit (LRT) line within the I-290 project area. LRT are steel-wheeled electric vehicles that may operate in mixed traffic or in a dedicated right-of-way.

Pre-Screen Finding: *NOT CARRIED FORWARD*

This concept is not being carried forward for further consideration because Heavy Rail Transit (HRT) already exists in the study area. It would be more effective to extend the existing HRT rather than add a new rail mode that requires all new vehicles, a transfer at the Forest Park station, and a new maintenance and yard facility.

C Related Improvements (that could be combined with other concepts)

The related improvements category includes suggestions that are compatible with other concepts. All of the concepts in this category were deferred to future rounds of evaluation since Round 1 focuses on evaluating single mode alternatives.

C1. Add express bus service within the project area

General Functional Description

This concept would add local express bus service within the project area.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C2. Interchange improvements and design

General Functional Description

This concept would involve the redesign of and improvements to existing interchanges within the project area. This category includes suggestions to reconfigure left-hand exits to right-hand exits, and right-hand exits to left-hand exits. This category also includes suggestions for roundabouts in the project area.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C3. Improve non-motorized facilities

General Functional Description

This category includes concepts that improve non-motorized facilities. Concepts include improvements to bicycle and pedestrian facilities along cross roads, adjacent arterials, and frontage roads, new non-motorized crossings of I-290, and bike and pedestrian trails along I-290.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C4. Improve transit stations

General Functional Description

This concept would improve the existing CTA Blue Line stations within the project area.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C5. Improve transit operations/connections

General Functional Description

This category includes concepts that would improve local transit bus operations within the project area by adding additional routes, improving transit service, and/or improving transit connections.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

DRAFT

C6. Add Transportation System Management /Active Traffic Management/ Intelligent Transportation Systems

General Functional Description

This concept includes Active Traffic Management (ATM), Intelligent Transportation Systems (ITS), and Transportation System Management (TSM) upgrades on both the I-290 mainline and adjacent arterials. This category also includes signage improvements along the corridor or on adjacent arterials. The specific design of these systems has not yet been defined.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C7. Add a cap over the expressway

General Functional Description

This concept would place a cap or cover over the I-290 facility in the project area.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C8. Double-deck I-290

General Functional Description

These suggestions are variations on the theme of building a two-level structure to carry I-290 traffic through the study area.

Pre-Screen Finding: *NOT CARRIED FORWARD*

Because existing I-290 is below grade with cross-streets approximately 20' above the expressway, a double-deck facility throughout the length of the study area would create a third roadway level approximately 50-55 feet above the existing I-290. Due to the noise, lighting and aesthetic impacts of an elevated facility, as well as increased construction and maintenance costs, this concept is not being carried forward for further consideration.

DRAFT

C9. CTA Blue Line in Subway/Tunnel or Elevated

General Functional Description

This concept would relocate the existing or proposed extensions of the Blue Line underground as a subway or to elevated structure.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C10. Arterial Improvements

General Functional Description

This category includes concepts that would improve arterial operations, including but not limited to improvements to the pavement, traffic flow and light synchronization on the two principal alternate parallel routes, Roosevelt Avenue and Madison Street.

Pre-Screen Finding: *DEFERRED*

This concept is being deferred for consideration as part of alternatives in subsequent evaluations.

C11. Other

General Functional Description

This category includes other suggestions that are location-specific and can be combined with other roadway or transit improvements. For example, park and ride and intermodal transfer facilities are included in this sub-category.

Pre-Screen Finding: *DEFERRED*

These concepts are being deferred for consideration as part of alternatives in subsequent evaluations.

DRAFT

2. Concepts Carried Forward to Round 1

A total of 21 concepts identified in Sections B and C of this appendix are being carried forward into the Round 1 evaluation as single mode alternatives. These 21 single mode alternatives can be further broken down into transit improvements, expressway improvements and arterial improvements and are summarized in the tables shown below. In addition to these single mode alternatives, 11 other categories of related improvements, as identified in Section C of this appendix, are being deferred to future screening rounds (i.e. Rounds 2 or 3).

Transit Mode Alternatives (9 total)

MODE	ID	Description
Blue Line Extension (HRT) 	HRT 1	From Forest Park CTA Terminal to Oak Brook via IL Prairie Path, Butterfield Road., and 22nd Street (elevated) from Forest Park CTA
	HRT 2	Terminal to Oak Brook via I-290 median (at-grade) and parallel to I-88 (elevated)
	HRT 3	From Forest Park CTA Terminal to Mannheim via I-290 median (at-grade)
Express Bus 	EXP	Various service from DuPage and northwest Cook counties to the Forest Park CTA terminal
Bus Rapid Transit (BRT) 	BRT 1	Oak Brook to Forest Park CTA Terminal - via Butterfield Road and IL Prairie Path
	BRT 2	Oak Brook to Forest Park CTA Terminal – parallel to I-88 (eleveated) and I-290 median (at-grade)
	BRT 3	Oak Brook to Cicero Avenue – parallel to I-88 (elevated) and I-290 median (at-grade)
	BRT 4	Oak Brook to Ashland Avenue – parallel to I-88 and along I-290 median (at-grade) – CTA Blue Line conversion to BRT from Forest Park CTA terminal to Ashland Avenue
	BRT 5	Lombard to Forest Park CTA Terminal – parallel to I-88 (elevated) and along I-290 median (at-grade)

Expressway Mode Alternatives (11 total)

General Purpose Add Lane			GP LANE	General Purpose Add Lane from I-88 to Central Avenue
Managed Lanes	HOV* Lanes	2+ Riders	HOV 2LL	Oak Brook to Racine Avenue
			HOV 2L	I-88 to Racine Avenue
			HOV 2W	Oak Brook to Central Avenue
		3+ Riders	HOV 3LL	Oak Brook to Racine Avenue
			HOV 3L	I-88 to Racine Avenue
			HOV 3W	Oak Brook to Central Avenue
	HOT Lanes*		HOT 1	Oak Brook to Central Avenue, 3+ Vehicles Free
			HOT 2	Oak Brook to Racine Avenue, 3+ Vehicles Free
	Toll Lanes		TOLL 1	Toll Existing I-290 Lanes, I-88 to Cicero Avenue
			TOLL 2	Toll I-290 with Add Lanes , I-88 to Cicero Avenue

*Both the HOV and HOT alternatives assume that two existing general purpose lanes (one in each direction) would be converted to HOV/HOT lanes along I-88, and along I-290 from Central Avenue to Racine Avenue. Along I-290 from the I-88/290 split to Central Avenue, two new HOT/HOV lanes (one in each direction) are added to the existing lanes.

Arterial Mode Alternative (1 total with 2 variations)

Arterial Widening	With Parking	ART 1	Widening of Roosevelt Road and Madison Avenue to 4 continuous lanes (2 lanes each direction). • Roosevelt Road from I-294 to Cicero Avenue • Madison Avenue from 25th Avenue to Cicero Avenue
	Without Parking	ART 2	

ID #	Proposed Alternative Comment	Disposition
1	I sent this comment in an email as well: I travel from downtown to Oak Brook and back daily M-Th, and have a suggestion for improving the westbound flow of traffic. It seems to me that much of the congestion before and after Austin Blvd. could be avoided if there were simply more signs earlier indicating that the left lane will become an exit-only lane. Obviously removing the left hand exits altogether would be the ultimate fix, but I believe that additional signs would allow a high percentage of drivers to move out of the left lane earlier than they normally would, i.e. before they have to come to a complete stop on the ramp and cut off people in the adjacent lane thereby causing a major slowdown.	**C6**
2	At Harlem Ave and Austin Blvd, please strongly consider replacing the center lane entrances/exits with traditional right lane entrances/exits. It seems that merging vehicles and exiting vehicles travel more slowly than typical center lane traffic. This results in more frequent lane changing or weaving by those trying to maintain the higher rate of speed typically found in the center lane.	**C2**
3	Reconstructing Eisenhower Expressway - main cause: Having driven this for years, I agree that 8 lanes to 6 lanes is a problem. My thought is that Oak Park with its lane 1 merges is also a major cause of the problems when combined with too many merges in too short a distance. Most drivers in this area have difficulty with merges to the inside lane. A more standard merge system in this area would be merges and exits to and from the outside lane #3 only. This may help the congestion also. It seems traffic mostly flows smoothly till Oak Park from either direction, then the problems start.	**C2**
4	I take I-290 daily and it is miserable. It is obvious new lanes are needed. HOV lanes would be a benefit also. I am happy to help any way I can.	**A1, A2**
5	Widening the Eisenhower seems like a smart and important move for IDOT. Has IDOT explored additional ideas? I-66 in Northern Virginia allows HOV traffic to use the right shoulders during rush periods. This adds capacity for merely the cost of lane markers and signs. I also support the extension of the Blue Line to Yorktown Mall, if it is run as an express service to downtown. The Eisenhower median provides enough room for 4 tracks - this opportunity should be explored. Also, the new line should, if possible, use the Illinois Prairie Path right-of-way between Forest Park and I-294.	**A1, A2, B2, B3, B10,**
6	The Eisenhower between Mannheim and Austin needs to be fixed. This has always been a problem. Make this section a 2 level road. This must be fixed ASAP!	**C8**
7	Need express lanes directly out to I-88.	**A2, A3**
8	You may want to consider thinking in three dimensions . . . lanes can be added vertically, as well as horizontally. Instead of taking away land from neighborhoods, express lanes (no trucks, destination downtown and Manheim) can be constructed on an elevated portion, with structure in the center median.	**C8**
9	Eisenhower needs to add a lane in both directions from Austin to Mannheim to ease congestion. Need to move Austin Blvd. and Harlem Avenue ramps from center of expressway to sides. Plus when the Ike gets backed up everyone uses Roosevelt Rd. and our side streets become busy because were the 1st southbound St. from Central Avenue.	**A1, A5, C2, C10**
10	Please consider work of the DuPage/Cook Corridor committee. Widening the ditch is not smart in light of the carbon economy that is coming in the near future. Augmenting public transit with extension of CTA Blue Line (light rail) BRT is a smarter long term strategy. Revitalization of the old inner ring suburbs with public transit (illegible word) design will help with the (illegible word) along the corridor. Land acquisition along the corridor will be costly. *Disrupt.	**B2, B7, B14, B17**
11	Please consider alternative route exiting I-290 to 25th through Wedgewood then to Beach. When I-290 is backed up people exit and block commercial building from entering or leaving. Cars doesn't help local commerce. Taxes in Broadview are outrageous. Many tenants will be willing to sell their building if the taxes don't improve.	**C2**
12	Encourage metro commuter usage by providing quick, safe, convenient, high speed rail from key West node of I-290/I-294/I-88 to downtown at abandoned U.S. Post Office Building in the Southwest Chicago loop.	**B13**
13	Considering trends in future oil prices and the need to cut carbon emissions the best plan is to look to the future and figure out how to get people out of their cars. Enhanced public transit via a blue-line extension makes more sense than adding lanes for increased vehicular traffic. Please consider the input of regular citizens, especially those living near the expressway.	**B2**
14	Please also work with the CTA to extend the blue line. The blue line should be extended as far west as possible (Aurora-wishful thinking). Due to limited land you might consider an underground subway city like New York. There would be less car congestion if a railway system was extended. There should be 5 or 4 lanes on each side, preferably 5. Right now, the Hillside strangler is congested because there is too much traffic from I-88, 290 (West), Roosevelt Rd, and Mannheim Road. Please look at Detroit's expressway system, they have 5 lanes on each side. If Detroit can do it then Illinois can do it too. Please get rid of the ramps on the center of the expressway, they should all be on the right side. Sign should be in big fonts and highly visible before the exits so people don't switch lanes at the last minute. Another idea is to look at Germany's expressway system. They control the flow of traffic electronically. They close and open lanes based on traffic.	**A1, B2, C2, C6, C9, C11**
15	Currently, I-290 is a four-lane roadway (both inbound and outbound) from downtown Chicago to Austin Blvd. During times of heavy traffic, it is typical for outbound traffic to become congested at this choke point and back up for miles. We need to add a lane to both sides of the expressway, and especially on the outbound side.	**A1**
16	25th Street ramps cause tremendous back ups not only on the Eisenhower (East Bound) but cause congestion under the train tracks along Beach St. all the way to 25th. Business locations along Beach have trouble exiting onto Beach at times because of the way the ramp is located so far from 25th street. Back ups also occur on the Eisenhower because of the stop sign at the end of the ramp. Trucks use 25th because they missed the Mannheim exit coming from 88 East Bound.	**C2, C10**
17	Thank you for holding this meeting but: By holding this meeting in an area not easily accessible by public transportation you are skewing the results greatly. Extension of the blue line at least to Mannheim, preferably to Oak Brook, would eliminate enough automobile traffic to, very likely, eliminate the need for expansion. This is the least disruptive, possibly least expensive because no land would need to be purchased, option. Try it first! If it doesn't solve all the problems, expansion can always be considered later. Our kids want expansion of public transportation.	**B2**
18	Don't stop blue line until you reach the internetion of I-290, I-88, I-294. Add High speed rail for commuters. Conduct study that determines how much time.	**B2, B13**
19	The road obviously needs to be widened but the state should not neglect the available land that exists in the current footprint of the CTA rails. Turning the rail into subway and widening the road into currently owned land is a financially responsible decision. Also, new expressway should be designed with the capability to be come "double-deck" in the future as capacity needs increase.	**A1, B2, C8, C9**

ID #	Proposed Alternative Comment	Disposition
20	Extend the Blue Line and don't widen the Ike! We spent $140 million on the "Hillside Strangler" and did not reduce travel time at all. Widening the Ike would be a colossal waste of money.	**B2**
21	To add lanes w/out widening the trench, more. CTA tracks under ground! Make it a subway, like much of it already. Make it toll with congestion pricing.	**A4, C9**
22	A possibility would be eliminating Harrison , or as previously considered, use the CTA's "right of way" lanes to add a lane. Stop patching the pavement and rebuild it! I'm concerned that, due to funding or politics, that this study will not get past Phase I and then it will start all over again in another 5 years.	**A1, C10**
23	The loss of property to Columbus Park is minimal. Must importantly is that both East and West bound traffic with entrance and exits be retained at Central and Eisenhower. 2010 parishioners exit W. I-290.	**C2**
24	Please consider going to Congress Washington D.C. to inquire the feasibility of moving the R.R. in Forest Park on the Southside of the expressway. Or can the El train be truly elevated above and in-between the directions of the expressway.	**C9**
25	A subway dug by the deep tunnel machines could help obtain the space now taken up by the above ground train. Express trains from Oak Brook area to downtown on the hour would make it more appealing. This would greatly reduce the land acquisition needed and could start moving people into mass transit.	**B4, C9**
26	Extending the CTA (Blue Line) toward the west suburbs will give alternatives to commuters both to Chicago or to the west shopping centers. Yes to the Oak Park Cap.	**A1, C11**
27	1. We must think long-term on this. 2. We must extend rail transit along the corridor above all else. 3. We must discourage automobile commuting. 4. HOV lanes will not Work-- You need 7 lanes each way and still more will drive. 5. Widen the highway and still more will drive. 6. Make the CTA to Hillside or Oak Brook run express to the Loop and suburbanites will take it and especially every-day commuters.	**B2, B4**
28	If lanes are added, more people will drive downtown and back fill them up, just as happened after the "Hillside Strangler" was fixed. We must encourage more people to take public transit, not drive. Extend the CTA. Don't add lanes to to Ike. Find a spot in the trench for a bicycle route. Add parking near Metra stops. Get more cars off the roads, for the sake of our planet. And convince me this whole process isn't a sham.	**B2, C3, C11**
29	No Cap of Ike through Oak Park--Estimated to cost billions we don't have. Acquire CN Railroad property as needed from Central to DesPlaines.	**C11**
30	Thank you for soliciting public input on this issue. Also, thank you for following the context sensitive solution decision process for this study. Briefly my concerns are as follow. The Blue Line stations in the study area all need 100% repair to improve access and usage. Include BRT as a solution option. Move the Oak Park ramps to the outer lanes. All the bridges in Oak Park over I-290 need 100% replacement to improve safety, access, and traffic flow. Support the decision of the I-290 ditch between Austin Avenue, and Harlem Avenue--Cap the Ike!	**B7, C2, C5, C7**
31	I live six houses south of Garfield-- near I-290. I oppose the expansion on I-290 to add lanes. This would completely disrupt our neighborhood and negatively affect property values, encouraging increased traffic is a step backwards for the environment-- expansion of public transportation should be considered instead.	**B2**
32	Couple of Points: 1. EB ramps (left) from 290 to Harlem and WB ramp (right) from 290 have green light at the same time making it very unsafe. Should have separate phasing. 2. Too much traffic on Harlem Avenue (North leg from 290). Need improvements on Harlem. 3. Left ramps should be taken out along I-290. Temporary fix could be to provide warning signs on I-290 explaining that next ramp is on left side.	**C2, C6, C10, C11**
33	Concerns with the possible annex of Community for roadway expansion? Need more noise abatement (sound barrier between Laramie and Central. Also concerned with excessive traffic on Flournoy when traffic exit at Laramie travel down Flournoy to advance around traffic and Central. Excessive speed-trucks etc.)	**C6, C10**
34	Comment Form 1: 1. Retain interior ramps at Harlem and Austin! 2. Minimize taking of land/existing properties! 3. Recognize that additional lanes will not ever be large enough to accommodate traffic growth in area. 4. Forget HOV lanes- won't be used 5. Expand rail service and systems Comment Form 2: 1. Retain interior exists at Harlem and Austin! 2. Publicly identify potentially affected properties.	**B2, C2**
35	What is the impact on the neighbors of highway? No need for additional lanes. Spend $ on public transit instead, look at regional transit studies, fund 3rd phase of RTA study, no need for more lanes.	**B2, C2**
36	DO NOT WIDEN THE HIGHWAY. BUILD MORE RAILLINES FOR METRA, CTA, AND FREIGHT. DO NOT BUILD A CAP.	**B2, B10**
37	What about using managed lanes to increase the throughput. Will Need a combination of alternates (roadway, rail, and transit) to meet long term needs.	**A2, A3, B2**
38	I would like to express my concerns about the upcoming 1-290 rehabilitation/expansion. understand that the roadway is in desperate need of repair. And while 1 am a proponent of increasing public transportation options in order to decrease congestion, I am not deluded enough to think that there will be no expansion of 1-290 from Austin Blvd to Mannheim Road. ram however concerned how this will effect my family and home because of my proximity to the current roadway. Any expansion that moves me from my house is unacceptable. I would 1 ike to see a plan that takes a number of issues into account. First, not to be so shortsighted as to think that only roadway xpansion or increased public transportation optIOns will be the answer to local traffic congestion. A concerted effort needs to be made to include expansion of both in order to be successful of expansion. Second, I am of the opinion that there is much wasted space in the current configuration that, with the proper planning, could be used to add lanes to 1-290 and increase public transportation. Case in point: the freight train tracks next to the CTA lines at Oak Park avenue have been used as a storage for an empty container train. This train has been in the same place since April, 2009. If this line is so unneeded, then the hree sets of tracks there can be condensed. Third, I feel that the CTA Blue Line is an essential part of the area and it needs to be rehabilitated. The Austin, Oak Park, and Harlem stops are a disgrace to the area and Regional Transit Authority. I have only seen this much rusting corrugated steel in third-world shanty towns. The Blue Line has the ability to go underground, as it does through downtown and at other points along the line as it travels to O'Hare. 1 do not see a reason why the Blue Line cannot operate under a section of I-290 through Oak Park in order to make room for additional lanes of traffic without expanding the size of the current "canyon" that divides my town. Finally, I \vould hope that covering, or capping, parts of 1-290 would still be an option as part of any rebuild of the roadway. While 1 would hope the citizens of Oak Park would understand that a full "cap" of the Ike is not feasible, 1 still believe that a partial cap is necessary. A previous study conducted by the Village of Oak Park showed that partial "caps" in a couple of areas would help reclaim lost space and help unite the village that is shaved offby nearly a third by the canyon of the roadway. Thank you for you time and for taking my concerns seriously.	**A1, B2, C5, C7, C9**

ID #	Proposed Alternative Comment	Disposition
39	I am writing on behalf of myself and the many concerned citizens of the area potentially impacted by proposed expansion of the 1-290 corridor between Austin Avenue and Mannheim Road. We strongly oppose plans to expand this corridor with additional lanes or reconfiguration of exits. I support ONLY the extension of the Blue Line west to Oak Brook, either as a surface line or subway, but not any of the other proposals involving HOV or other added lanes. Only this solution will reduce congestion and offer the residents of the city and these west suburban communities who don't own cars access to the businesses, employment and shopping opportunities of the western suburbs. There are a number of folks out there that believe adding lanes, moving the exits. and other highway-based improvements will solve "the problem." However, such positions reflect a fundamental misunderstanding of the problem and insufficient awareness of alternative solutions. 1-290 was congested in 1959, a mere four years after having opened. Will a short section of added highway capacity make an appreciable difference? The only true solution to congestion in heavily traveled urban highway corridors is to get people out of their cars. In order to do that along 1-290 between Oak Brook and Chicago, there must be a rail extension to the Oak Brook area, perhaps combined with other incentives to encourage mode shift. Models suggest that congestion could be reduced as much as 30% to 40% simply by combining rail transit and increasing the cost of driving. If you keep doin' what you've always been doing, you'll keep gettin' what you've always got: Added highway capacity yields added congestion. If you build it, they will come!	**B2**
40	As a resident of and the Sustainability Manager for the Village of Oak Park, I am writing to urge lOOT to adopt a regional transit solution, rather than the formerly proposed highway expansion, for the 1-290 corridor between Oak Brook and Chicago, Illinois. There must be a new paradigm for the 1-290 corridor, one in which it is envisioned as a 21 st century high-performance transit corridor that disfavors peak period automobile traffic, reduces congestion by getting people out of their cars, improves air quality, reduces greenhouse gas emissions, and provides for solution permanence. Bus Rapid Transit (extra long buses called "BRr) and carpools (HOV) simply can't do that on 1-290, between Chicago and Oak Brook, a heavily congested urban corridor where population and job densities call for rail solutions. A rail solution is not only appropriate, but the only solution that can achieve permanence and not simply serve as a placeholder for the next major investment to "solve congestion." Sure, we can build our way out of congestion by routinely adding highway lanes on a periodic basis, but how many lanes and at what costs, including economic, social, and environmental considerations for communities along the 1-290 corridor like Oak Park? Ten highway lanes would be required to move the same number of people that a CTA train does, and the CTA train does so with significantly fewer adverse environmental impacts. Where density is appropriate, and it is along the 1-290 study area, rail is truly the only real solution; a placeholder HOV/BRT facility is imprudent where conditions already warrant and would support rail service. Let's create the first high performance transit corridor of the 21st century, rather than the last great highway project of the 20 th century. The communities along this corridor are confronting the leading edge of a perfect storm fueled by national security concerns, environmental degradation, economic stress, and a federal highway fund that is insufficient to meet current and anticipated highway needs. Surely we have the collective sensibility to recognize that more rubber tires on more highway lanes using more and more foreign fuel is not the way to survive the storm. While highways continue to provide great value, the manner in which we manage mobility and urban congestion during peak usage periods is receiving a failing grade. It is time for change. Therefore, I am urging lOOT to forego the idea of highway expansion along 1-290 and adopt a regional rail solution which includes expansion of the CTA Blue Line as the only long-term solution to congestion along this urban orridor.	**B2**
41	Can we have bike lanes? I hope so.	**C3**
42	Be more visitor friendly if you want more revenue. Give plenty of earning with signage for Austin and Harlem. (Make them larger so people can see them from a distance.)	**C6**
43	This region needs to develop a managed lane network with high performance bus transit on the expressway and tollway system. This would complement existing (illegible word) transit/commuter rail network. I-290 could be a (illegible word) first element of such a managed/ ok network. We need to diversify our investment in transportation by using highway effectively for cars and transit. prefer this strategy (managed lane) over ideas like the STAR Line/ Circle Line, or other rail line extensions.	**A2, A3, B7**
44	I would encourage the study team to: A) ease pedestrian access to Blue Line Stations via bridges over the 290. B) Include best technology to reduce noise impact to local community (e.g. road surface, walls, etc.) C) Look at ways to mitigate heavy truck traffic in adjacent communities.	**C3, C11**
45	NO LANE EXPANSION!!! 1) Adding lanes won't reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. 2) If we were to build all the lanes traffic engineers say is necessary to "solve" congestion, the Ike [I-290] would be 12-14 lanes wide. Clearly we aren't going to do that, so let's find a better solution BEFORE we expand the Ike [I-290]. 3) More highway lanes means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. 4) Extending the CTA Blue Line to Hillside is a better solution. It would increase mobility, solve congestion problems, and improve our communities.	**B2**
46	Do not widen the existing profile of the Eisenhower Expressway. Use alternate solutions. More cars, noise, pollution is not the solution. Extending public transit and capping the Ike [I-290] are good solutions.	**B2, C7**
47	Please DO NOT expand the Eisenhower X-way. What we really need are more public transportation options--how about extending the Blue Line westward, or getting some express buses on I-290?	**B2, B15**
48	The days of destroying communities to build bigger roads is over. Please think about serving transportation needs in fresh ways that conserve energy. Could the Blue Line be extended westward?	**B2**
49	More lanes on the Eisenhower means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. Extending the CTA Blue Line to Hillside is a better solution. It would increase mobility, solve congestion problems, and improve our communities.	**B2**
50	I strongly oppose plans to widen the Eisenhower or otherwise encourage auto traffic. Instead, we must expand public transit. I will be watching this project closely, as will my friends.	**B2**
51	I do not support the addition of more lanes for the Eisenhower Expressway. I believe adding an extension to the Blue Line CTA is a much better solution on many levels.	**B2**
52	Increasing public transportation is a better long-term use of funding than expanding the Eisenhower. Adding lanes won't reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. If we were to build all the lanes traffic engineers say is necessary to "solve" congestion, the Ike [I-290] would be 12-14 lanes wide. Clearly we aren't going to do that, so let's find a better solution BEFORE we expand the Ike [I-290]. More highway lanes means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. Extending the CTA Blue Line to Hillside is a better solution. It would increase mobility, solve congestion problems, and improve our communities.	**B2**

ID #	Proposed Alternative Comment	Disposition
53	I would like to add my voice to the opposition to any effort to add lanes to the Eisenhower from Cicero Ave to Mannheim Rd. I have driven that route both as a commuter and for personal reasons for many years. I also live in Oak Park. I believe we must offer a Blue Line extension with park & ride options to limit the negative impact of additional traffic lanes. More lanes will translate to more cars and traffic, thereby increasing noise and pollution. In the long-term there will be negative effects in the surrounding neighborhoods where there are lovely homes and trees. Undoubtedly, adding a Blue Line and even a Green Line Extension would be better and cheaper. Offering a park & ride option reduces the already stressed parking situation in Chicago and is less expensive for the commuter. Traffic safety would be assured given that many people tied up in traffic are not attentive - talk on their cell phones and text while driving. Those activities may be safely conducted on the train with no danger to other motorists.	**B2, B5, C11**
54	What about improving public transportation? And, keeping rider costs low?	**C5**
55	Regarding the I-290 expansion, I would like to say that no matter what is done to expand the Ike [I-290] to a larger lane format, traffic congestion will continue to build and grow unless a convenient alternative method is devised. Strong consideration toward public rail expansion with possible express trains and use of driving lanes using hybrid alternative fuels, to deter added pollution and unwanted traffic. It has to be part of the deal.	**B2, B4**
56	Why are you expanding the Eisenhower? Why are you not creating Mass Transit for this cooridor? The North Shore has over 30 miles of Mass Transit available to them and the Westside has 10! Why such a disparity? GO GREEN!! Spend the money on Mass Transit!!!!	**B2**
57	Please consider a different apporach to traffic in Illinois. If we lengthen the Blue line to Hillside or even to Oak Brook-- we are saving the environment, reducing traffic (thereby increasing flow) and strengthening our public transportation system. I take the Blue Line everyday from Oak Park to Clinton Stop---I love it! PLease consider that expansion over adding more lanes- remeber the Hillside expansion at mannheim was supposed to reduced traffic flow and its still the same. Lane additions are not the answer! Thank you! Christine Horwitx Oak Park, IL	**B2**
58	I wish to let the IDOT know that I oppose plans to add capacity to the Eisenhower Expressway. I feel that extending the CTA Blue Line to Hillside and beyond is a better solution. The Chicago area lags behind transportation systems in other major cities, such as Washington D.C. and London. Let's solve a 21st century problem with a 21st century solution.	**B2**
59	I attended the forum in Hillside but I have to say I have little confidence in your work project. It seems that IDOT could really care less about the users of the system or the neighbors. I drive for a living and am continually reminded of this reality every day. Why is it cheaper to black top than to use hardened cement for roads. The answer is because you put no value on my time. This is unfortunate because your interference with my work days reduces my income potential. I guess that is someone else's problem to a bureaucrat. This reality is only exacerbated by the rolling mid-day work crews. Who cares that it causes accidents and interferes with peoples lives as long as my budget is ok. As far as the Ike [I-290], as an Oak Park [resident] I am confident you will take more land, change the exit ramps because it's simple and really who cares what we want? Leave the left hand exit, use a cantilevered structure where there is no dirt to remove, have your extra lane and leave a minimal impact, please.	**C2**
60	Do not add more car lanes. Add protected bicycle lanes, mass transit, and parking for mass transit. WAKE UP!!!	**B2, C3, C11**
61	It seems that rather than increase highway capacity, which usually encourages additional automobile traffic, IDOT ought rather to be partnering with other local transportation agencies to create alternative commuting and transit options. The tremendous expense of fixing the Hillside strangler made such a minor impact and only moved the congestion elsewhere. If the CTA Blue Line were extended to Hillside, daily commuter conditions would likely improve more than the impact of adding lanes.	**B2**
62	Expanding the Ike [I-290] will not solve the problem, that has been proved nationally; build it and they do come. It is time to try some new thinking. We suggest you try alternate forms of transportation. Also a national green alliance will form to defend historic Columbus Park already been scared by roadway expansion, others will protest the taking of any land and the demolition of any residences. It is time for a change.	**B2**
63	I know not much information is available yet regarding this study, but I would be strongly opposed to widening the Eisenhower, even if the additional lanes will only be HOV lanes. We need to focus as a country on getting people out of their vehicles and giving them alternative forms of public transportation, not encourage continued use of the car by providing a bigger "parking lot." Vehicular congestion will always be an increasing problem if we do not make a shift in our culture and move away from our dependence upon the car. I understand there could be potential to extend the CTA Blue Line to Oak Brook, which I feel would be a much better alternative to widening the Eisenhower. I have also heard about the possibility of high speed bus lanes being proposed in our area, and am wondering if that is also being considered as an option for this project. It is not as ideal as extending the el lines, but I feel it would be a better step than a wholesale widening of the expressway with "carpool" lanes. Regarding the CTA expansion, I know that IDOT does not have any control over what happens with the CTA, but if enough residents and commuters bring this up, I would hope the information could be passed on to the CTA or RTA.	**B2, B7**
64	I live in Oak Park, and I am opposed to the proposed expansion of the Eisenhower. We do not need more air pollution and noise in our communities and it's time to think of greener alternatives. We learned from the last expansion (Hillside Strangler) that adding more lanes do NOT reduce congestion very much at all. Commute times remain virtually the same after all that money and effort! Extending the Blue Line makes much more sense from an economic and environmental perspective both. It would reduce congestion, be a greener solution, and would improve our communities rather than create even more urban congestion.	**B2**
65	I was unable to attend the public hearing on expanding the Eisenhower through Oak Park, but want to comment that I find the idea very troubling. We western suburbanites badly need expanded rail transportation options, NOT more highways which primarily benefit the wealthy, and continue the degradation of our local biosphere. Extend the Blue Line, please!	**B2**
66	Please don't widen the Eisenhower without extending the Blue Line FIRST. Please, do that and observe how much traffic is reduced by this necessary and forward-thinking improvement!	**B2**
67	Let Illinois show how "green" it can be by finding a solution to the Eisenhower's congestion that IS NOT more congestion. If you make another lane, more cars will come. Add on to the already existing CTA or find low emissions buses for commuters. Making one of the existing lanes each direction could be designated an HOV lane. Think people, THINK.	**A2, B2**
68	As a long time Oak Park resident, I do not want the additional pollution another lane on the Ike [I-290] would cause. The lane would also not solve the congestion problem. Many studies have shown new lanes just increase traffic, creating more pollution for my family. We need public transportation that would allow movement to the western suburbs.	**B2**

ID #	Proposed Alternative Comment	Disposition
69	Please do not add additional lanes to I-290. I feel that public transportation by means of extending the Blue Line further west is a much more environmentally-friendly option and we should be encouraging people to take public transportation. I think the additional lanes will only increase traffic and do little to improve commute times.	**B2**
70	I am particularly concerned about the fact that there is serious consideration about widening the Eisenhower Expressway. There have been numerous studies which suggest that expanded expressways are obsolete before the expansion is completed because of the increased volume of cars. In this economy, we cannot spend money in such a foolish fashion. We expect more of our government. Another very important consideration is that as we as a country are trying to become less reliant on fossil fuels, it makes more sense to spend the money to invest in public transportation options. Besides the obvious "green" considerations, public transportation would clearly help more people save money, find and travel to jobs and such a move would most likely help with the redevelopment of some of the western suburbs that have fallen on hard times and the City of Chicago as well. We do not need government wasting more money on antiquated transportation systems. NO EISENHOWER EXPANSION.	**B2**
71	I heartily oppose the widening of the Eisenhower Expressway between Cicero Ave and Manheim Rd. Traffic studies have shown that adding lanes to existing highways only attracts more and more cars, with the attendant pollution, congestion, and property acquisition. As a resident of Oak Park, I object very much to the idea that parts of our village would be lost to this kind of property take-over. The Hillside Strangler is an example of how $140 million was wasted, in order to "fix the problem", but it has not fixed the problem. The congestion just moved down the road. As a resident of Oak Park, I would much rather see the money go for an extension of the CTA Blue Line to Hillside. This would ultimately benefit the economy by increasing our shopping options and it would contribute to a greener world. Let's not waste money again! Please listen to our voices! Don't widen the Ike [I-290]!	**B2**
72	There is currently an issue on the eastbound side with motorists who use the Mannheim Road exit as an 'express' lane to get back on the Eisenhower further east. This causes an unnecessary merge near 25th Ave and the resulting congestion. It also poses a safety issue as these motorists tend to congest the ramp for motorists who use the ramp for its intended purpose (to exit). Need a pilot study to determine if enforcement of the 'exit only' nature of the ramp eases congestion. If the Roosevelt Rd entrance is closed at rush hour, force all traffic to exit at Mannheim. The other option would be signs on the east bound side warning motorists that they must heed the 'exit only' designation or face a citation.	**C2, C6**
73	Heading east, right before the Manheim spur, can be a total mess (I'm sure you all know this already, but I'm just saying). It'd be great if you got the 4 lanes going down to more than one under that viaduct. [Darmstad Rd]	**C10**
74	As someone that uses the Eisenhower regularly and lives within three blocks on the interstate in Oak Park, I want to lodge my opposition to any lane expansion of the Eisenhower. Many studies - and our own experience in the greater Chicago area - have shown that additional lanes do little to ease traffic congestion. The disruption to homes and lives that such an expansion would cause would bring much greater harm than the expansion warrants. I recommend that IDOT look to innovative traffic relief measures that include expanded public transportation through the extension of the CTA's Blue Line to address traffic problems rather than spending scarce resources on additional lanes.	**B2**
75	As an Oak Park resident, I feel this would have VERY DETRIMENTAL affects to our community and my family's quality of life. Adding lanes won't reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. If we were to build all the lanes traffic engineers say is necessary to "solve" congestion, the Ike [I-290] would be 12-14 lanes wide. Clearly we aren't going to do that, so let's find a better solution BEFORE we expand the Ike [I-290]. More highway lanes means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. Extending the CTA Blue Line to Hillside is a better solution. It would increase mobility, solve congestion problems, and improve our communities.	**B2**
76	How about adding an elevated non-stop year round bike lane along or on top of the Eisenhower? This would alleviate cyclists that drive downtown because they are tired of getting accosted by folks hanging out in the city, especially on the West side. Also widen the pedestrian/bike/disabled bridge that crosses the I-290 at Home Ave in Oak Park. Also extend the CTA Blue Line West to further reduce automotive traffic.	**B2, C3**
77	I am opposed to widening the Eisenhower expressway between Cicero Ave and Manheim Rd. This is an expensive project with little or no benefit. I would support a long term solution such as expanding the reach of the CTA Blue Line further west. We have seen time and again that expansion projects, such as the Hillside strangler 'fix', yield little to not reduction in congestion.	**B2**
78	DO NOT EXPAND EISENHOWER. Adding lanes won't reduce traffic congestion. Look at the Hillside Strangler problem. A better solution is extending the CTA Blue Line to Hillside. It would increase mobility, solve congestion problems, and improve our communities.	**B2**
79	Adding lanes won't reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. If we were to build all the lanes traffic engineers say is necessary to "solve" congestion, the Ike [I-290] would be 12-14 lanes wide. Clearly we aren't going to do that, so let's find a better solution BEFORE we expand the Ike. More highway lanes means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. Extending the CTA Blue Line to Hillside is a better solution. It would increase mobility, solve congestion problems, and improve our communities. Please oppose the expansion!	**B2**
80	It seems that the problem of getting people and goods from east to west focuses on the Eisenhower Expressway. That is a limited view of a problem. If the problem moving automobiles from east to west then perhaps that expanding the Eisenhower Expressway would be a temporary solution. Yet the true problem of moving people and goods will remain unresolved. The solution would be multi-faceted and seeking multiple solutions from a variety of sources. Unfortunately, it does not appear that the Illinois Department of Transportation has that capability. It lacks a broader perspective of the true problem, and focuses on the automobile-an inefficient and damaging form of transportation of people and of goods. When I.D.O.T. and policy makers view and defines the problem differently, then perhaps a change for people, the environment, for communities and the future of transportation will be addressed appropriately.	**B2**
81	Please do NOT widen the Eisenhower expressway. Extending the Blue Line is a much more fiscally and environmentally responsible option. Encouraging more car travel is the last thing we need to do. It will only bring more pollution, more noise, more global warming. Is it worth all that to save a few people a few seconds of travel time? Obviously not. Widening the Eisenhower is an incredibly short-sighted "fix" that ignores the long-range problems. Please don't waste our money on this!	**C5**
82	I urge that serious consideration be given to extending public transportation (e.g., the CTA Blue Line) west in lieu of destroying portions of communities in order to add additional lanes to the Eisenhower. We have recently experienced high gas prices and will likely do so again and again. I firmly believer that it is in the public interest to provide public transportation alternatives to driving.	**B2**
83	Extending the Blue Line is the best way to go. Adding more car/truck lanes is very backward thinking and I doubt that it will solve anything.	**B2**

ID #	Proposed Alternative Comment	Disposition
84	I am writing to let you know I am opposed the expansion of the Eisenhower between Cicero and Manheim. Our communities would be better served by extending the Blue Line. This would reduce pollution and provide people more affordable ways to travel. Adding more lanes to the Eisenhower is not a long-term solution. Expanding public transportation should be the first option.	**B2**
85	Please do not widen the Ike [I-290]. It will not solve the congestion problem. You would need at least 10 lanes to solve part of the problem. Oak Park does not need more pollution. Extend the Blue Line to Hillside! Extend the Blue Line to Hillside!	**B2**
86	The expansion of this expressway is essential. It is ridiculous that there are horrible delays due to the narrowing of the lanes at Austin, and that this has continued for years. I live in Oak Park, and I am an advocate of the addition of one additional lane in each direction. Perhaps the lowering of the lanes would prevent housing loss. Is this an option?	**A1**
87	I fully support adding a fourth lane to the Eisenhower Expressway between Austin Blvd and Mannheim Road. This would correct one of the worst traffic bottlenecks in our region and fix a design flaw that has existed since the highway was built in the 1950's. Hopefully the fourth lane can be added in the existing right of way or "trench" that the highway currently occupies. Every effort should be made not to have to take any adjacent property unless absolutely necessary. I would also support extending the CTA Blue Line to Mannheim Road, where a large parking lot and transit center could be constructed at the old Hillside landfill. Free commuter parking could be offered to commuters taking the Blue Line. First and foremost. please fix a fifty year old problem and add the fourth lane to the Ike. I look forward to being able to attend public hearings to support this vitally important project for our regions economy and quality of life.	**A1, B2, C11**
88	Come on folks! Widening the Ike to 4 lanes each direction is a stop-gap measure, just like the Hillside strangler is still poor. What we need is MASS TRANSIT improvements!!!	**B2**
89	I'm an Oak Park resident who opposes widening the Eisenhower for several reasons, namely: Adding lanes will not reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. Why spend tens of millions more to end up with the exact same problem? Research shows that the Ike [I-290] actually would require an additional six to eight lanes to handle congestion. Given that this is not going to happen, a better solution to congestion needs to be created. Expanding the Ike [I-290] will only contribute to the problem of climate change—at a time when we should all be looking for solutions. One alternative would be to extend the CTA Blue Line to Hillside. This would improve congestion problems and contribute to, instead of detract from, our communities. This is such an opportunity for Illinois to be a leader, instead of a joke on late-night TV. Please don't blow it.	**B2**
90	I think expanding the Eisenhower is a bad idea. You spent $140 million expanding the Ike [I-290] at Hillside and all it caused was more congestion. You need to please start thinking about increasing public transportation through the corridor. Rail lines leading out to the western suburbs makes a lot more sense than expanding a lane of highway for the 4 or 5 miles up to Austin, it will only increase vehicle usage and create the same problems with no solution. Public transportation ridership is way up, capitalize on this and expand rail.	**B2**
91	As a resident of Oak Park and user of the Eisenhower Expressway, I'm concerned about efforts to increase the freeway's capacity for two reasons: 1) it would increase pollution and noise in the adjacent communities, and 2) it incents further use of automobiles (typically containing only one person) for commuting. Before we do anything to widen the Ike [I-290], let's first extend the CTA Blue Line west to Hillside (or beyond!) to provide greater commuter capacity. This would help contain emissions, reduce congestion and energy use -- and would probably provide a financial boost for the beleaguered CTA!	**B2**
92	I have developed these comments for IDOT's Phase 1 (Environmental and Engineering Study) for the I-290 corridor evaluation. Will IDOT re-engineering a few on/off ramps along with increasing lanes really solve the transportation challenges facing the Chicagoland region? Will increasing capacity relieve automobile congestion for more than a few year period? I say that the money invested in re-engineering I-290 could be better spent on thinking beyond roads and automobiles. When evaluating transportation needs, I would hope IDOT would expand its mind set from the road/automobile paradigm to a more holistic view of transportation. The continued expansion of roads is not a long-term viable solution to our society's transportation needs. IDOT should think beyond highways to increasing mass transit option for residents i.e. CTA Blue Line extension/expansion, bus and Metra service increases, regional transportation hub development along I-290, etc. Additionally, the inevitable rise in gasoline costs, a known finite resource, should be strongly considered. With increasing gas costs, more individuals will shift to mass transit use. When IDOT is evaluating the environmental aspects of the expansion, I would hope IDOT would consider global climate change and the health of the communities near the highway. Increasing automobile traffic will only allow our region to increase their CO2 emissions (adding to global climate change) and adversely affect the health of the residents the highway transverses (increased air pollution). The Chicagoland area has an extraordinary amount of public transit options for an American city; however there is room for so much improvement. Increasing the "livability" of the region will cause people to flock to Chicago as a place they want to live. Also, increasing mass transit needs will make this a place where everyone can thrive. Increasing the highway capacity of I-290 only benefit a small group of people with extra disposable income who can afford a car but it adversely affect many other people with less financial options by increasing air pollution by their homes and creating a situation that isolated them financially. If IDOT shifts their view and looks more at a holistic way to solving public transportation issues (i.e. expanding the CTA Blue Line west), this will be money spent that will benefit everyone. It will help many more individuals have more access to commerce and job opportunities. In summary, I believe that: I-290 should not expand the number of lanes; I-290 on/off ramps should remain as is; Public transit should be increased i.e. CTA Blue Line extension/expansion, increase in bus and Metra services, regional transportation hub to be expanded/developed; Any money spent towards expanding I-290 will benefit only a few individuals with higher disposable income but adversely affect many communities; and money should be spent on increasing mass transit therefore helping many more individuals have more access to commerce and job opportunities. In closing, I am perplexed why IDOT is performing this evaluation. The communities along the I-290 corridor went through a thorough public meeting / workshop process when evaluating these same topics in the Cook Dosage Corridor Study. I would hope that IDOT would not spend tax dollar money redoing a study so thorough performed before – the issues haven't changed.	**B2, B9, C11**

ID #	Proposed Alternative Comment	Disposition
93	I support the expansion of the Blue Line west, the addition of bus rapid transit service, and increased Metra service to address the transportation needs of this corridor. Furthermore, the Blue Line expansion should include a third track for express trains. There exists room in the current right-of-way for such track. The "problem" in this corridor is one of moving people, NOT vehicles. Widening I-290 will NOT result in less congestion. IDOT spent $140 Million to "solve" the problem of the Hillside Strangler and yet travel times remain virtually unchanged from before the solution of widening the road. I read of one study that found that the additional time lost by a car drivers during the construction phase will never be made up by sufficiently reduced travel times post-construction. The fact that travel times are virtually unchanged is testament to this fact. To add more lanes will only result in more people choosing to drive. This choice will then result in more pollution, more negative quality of life impacts, and, ironically, more congestion and NO reduction in travel times. Tax dollars will be better spent by expanding choices, i.e. expanding the Blue Line, better connectivity between the 'el, Metra and Pace. Expanding I-290 and incentivizing people to drive is irresponsible considering the fact that Chicagoland has the highest asthma rates in the nation. With a small exception, I-290 bisects communities that are lower income and suffer from higher asthma rates, especially among youth. More vehicles will only mean more missed school days and hospitalizations. I urge IDOT to truly become a department of transportation and not just highway building.	**B2, B9**
94	I live within two blocks of I-290 in Oak Park and I would urge you to consider all transportation options as you review the future of I-290. I am aware there are several community groups who have provided numerous solid alternatives to expanding I-290, so I will not repeat those here. Instead, I would like to your team to consider the benefits of being a leader in addressing the situation. IDOT and the other stakeholders have a unique opportunity to partner together and develop a solution to the traffic issues of I-290 in a way that is creative and environmentally friendly. In this way, your work on this project could serve as an example on how communities, government agencies, and action groups can work together to solve problems in an innovative way. Regardless of the specific benefits and plans being offered, please consider this an opportunity to be on the forefront of transportation planning and execution, which will serve your organization well and offer benefits in this project and future projects for years to come. Bottom line: true innovation often is rewarded more than merely repeating what has been done in the past. By executing smartly on this project, your team well be well positioned to secure additional funding and resources in the future.	**B2, B7**
95	I strongly urge you to reconsider your proposed expansion of the Eisenhower Expressway. In this era of improving our environment, creating 6-8 additional traffic lanes to accommodate cars isn't a wise choice when we are aiming to reduce noise and air pollution as well as preserve the beautiful landscape and structures around Oak Park and surrounding areas. A much better solution is to expand the Blue Line transit system. On a personal note, my family consciously decided to use our one car only when necessary; we much prefer using public transportation when going to the city; it saves us money and helps make our environment cleaner. For the sake of future generations, help us reduce global warming, put much-needed dollars towards the CTA through the Blue Line extension, and leave Oak Park the desirable community it is by not expanding lanes on the Eisenhower.	**B2**
96	If you built 8 lanes each way it will still be problematic. Any discussion of widening the Ike [I-290] must START WITH the idea of simultaneously extending the Blue Line to Lombard / Oak Brook.	**B2**
97	Please consider expanding public transit.	**B2**
98	As a resident of Oak Park, I am unhappy that IDOT has decided to try to ram through this project and ignore the studies that have been done concerning I-290 area near Oak Park. While your department may think that roads are the answer to all problems, this is a time in history where we need to focus much more on public transportation rather than widening roads. Expanded public transportation to the western suburbs is a much better solution to the traffic problems than is widening an already wide highway. Plus, widening I-290 through Oak Park will destroy some our most valuable assets: a library, a conservatory, and numerous homes. Such destruction is absolutely unwarranted and shows gross disregard for other options for improving transportation and gross disregard for the residents of our village.	**B2**
99	A net air pollution benefit is likely to result from an increase of capacity on the Eisenhower Expressway. An extension of the CTA Blue Line is less appropriate for the context, an expressway corridor. Significant transit capacity exists and improvement will result for flexible bus service traveling in an uncongested express toll lane connecting to the Forest Park Blue Line and other locations. The Eisenhower Expressway study should include as a principal alternative the addition of an express toll lane in each direction from Mannheim Road to Austin Boulevard. The Chicago Metropolitan Agency for Planning released preliminary measures for capital projects at the October 23, 2009 Transportation Committee, in which the results for such a project are very impressive. Additional capacity on the Eisenhower is forecast to reduce regional congestion by 50,000 hours per day. While no one can expect uncongested freeway travel this project has more benefit than any other evaluated. Result in a net air quality benefit. Slow moving or stop and go vehicles are more polluting than those traveling at speeds more typical of urban expressways. Pollution due to vehicle volume increase is offset by an improvement in the rate of pollution from each vehicle. Among highway projects only the Eisenhower expansion project indicates a net benefit for both fuel vapors and oxides of nitrogen. Result in a minimal diversion from transit of 3700 transit trips out of over 90,000 in the corridor. However, the CMAP model did not include improved and new bus service with uncongested travel to the Forest Park Blue Line Station. A express toll lane providing uncongested bus travel between the Forest Park Blue line and job centers in DuPage and Northwest Cook Counties is likely to attract thousands of additional riders. Enumerating existing transit infrastructure and daily trips questions the value of a Blue Line extension: Metra BNSF: 60,000 trips per day; Metra UPW: 25,000 per day; Pace Route 747: 1010 per day; Pace Route 313: 1278 per day; Pace Route 322: 2187 per day. Further, Metra has a New Start proposal to improve service on the UP-West to match that of the BNSF. Consider the land use context and the desire to see compact urban development, rail transit lines in expressway medians that necessitate long walks to the final destinations are less successful. The most successful transit lines in our region are within their own corridors. The north main branch of the CTA, that is the Red, Brown, and Purple lines, supports 180,000 riders per day. Metra's UPN, UPNW, MDW, and BNSF are examples of rail service to vibrate suburban downtowns, all running in their own corridor. An express toll lane supports transit service, allocates the scarce highway resource, and supports a portion of the construction cost. Tolls typical provide a modest subsidy to the accompanying transit service. A variable price in the toll lane will ensure good utilization; the lane will not be empty. High occupancy vehicles should not travel for free due to the availability of transit and the need to move more persons than is possible in private vehicles. In Houston and New York busses move up to 40,000 thousand people per lane per hour. Finally, some measure of reconstruction funding for the Eisenhower expressway, a benefit to all in the corridor, can be gained through toll funding of the single new express toll lane. The remaining lanes can remain untolled.	**A3, B2, B7, B9**
100	I hope that we don't just look at expanding an expressway here. With the upcoming need for a high-speed-rail corridor, adding high speed rail along side of, and near the Oak Park corridor under, the roadway would be a smart plan.	**B13**

ID #	Proposed Alternative Comment	Disposition
101	I am in support of IDOT closely examining a road improvement project that would provide a consistent 4 lanes on I-290 from the loop in Chicago to Mannheim Road. This type of project makes total sense for environmental and efficiency reasons. An incredible amount of time and gas are wasted in the unnecessary traffic jams caused by the reduction in travel lanes from 4 to 3 between Mannheim and Central Avenue in both directions of travel.	**A1**
102	A simple one, move the entrance/exit ramps to the outside of the expressway at Austin and Harlem to help reduce the amount of congestion caused by people not knowing the exit side or people waiting until the last minute to merge unto the next lane when not exiting the expressway. Plus a ramp at Oak Park Ave would be nice.	**C2**
103	I think we need to separate the questions of increasing capacity and design deficiencies. If a truly good and impartial study shows that design deficiencies are significantly slowing traffic then I am in favor of a redesign of the Oak Park section of I-290. However, redesigning the Oak Park section cannot and will not significantly increase capacity. An extension of rail service is a far better response to trying to increase capacity than adding extra lanes (especially HOV lanes) throughout I-290 and capacity certainly needs to increase. If people are interested in carpooling to use an HOV lane, they will be willing to use public transit and then rail is a preferred alternative.	**B2**
104	There is no question that the Eisenhower needs to be widened. When it was built in the mid-50s, the three lanes west of Austin Blvd were sufficient. That is no longer the case. I would suggest that if you are going to widen the expressway, do it right for once and for all. Widen it to four lanes and extend the Green Line (is it?) out to Oak Brook at the least and preferably Yorktown. That area is growing and has no public transportation to speak of. An extension of the el would be a boon to the depressed towns of Maywood, Broadview, Bellwood and Hillside.	**A1, B2**
105	I live in Oak Park. I see the problem with congestion not stemming from "too few lanes" but from not enough public transportation out to areas like Schaumburg where a lot of the jobs seem to be going. Why not take a better look at where all of this traffic is coming from...and going to...then make a decision as to whether or not to cut a new lane into a historic suburb like Oak Park. Expanding rail...there's your answer. How about a collar Metra line running North/South and intersecting with some of the lines that go into the city?	**B10**
106	Do not relocate the exit/entrance ramps at Harlem and Austin in Oak Park. These are absolutely necessary.	**C2**
107	The lane exit at Austin is wonderful. Likewise at Austin entering the Ike [I-290], works well. Harlem going west isn't as smooth. Considering the population base of Oak Park and surrounding communities improving Harlem and leaving Austin's exit as is makes sense.	**C2**
108	Thanks someone can see a problem and does something to fix the problem. Add 2 more lanes, add 4 more lanes, but fix the problem. Maybe public transportation will be great in 2040. For now, we have millions of vehicles we need to move east and west through the I-290 system. Also, EXIT to the right.	**A1, B2, C2**
109	The exits at Austin and Harlem would work better if there was a lane dedicated to exiting at those spots! People use the lanes to ditch and get in front of the other traffic that is westbound and not exiting at these streets. We need more lanes to help carry the load of traffic here.	**A1, C2**
110	Please, please, please widen the Eisenhower at Harlem !!! Get rid of the bottleneck.	**A1**
111	Leave the expressway ramps open at Harlem Ave and Austin Blvd.	**C2**
112	I would like to go on record as being opposed to the expansion of I-290 to add additional lanes. I live very close to the expressway in Oak Park, and have many concerns: decrease in property values; increase in pollution; disruption to community during construction; not a viable solution - traffic will only increase (fairly recent expansion at Hillside did NOT solve the problem it was intended to solve - let that be a LESSON LEARNED). Public transportation should be expanded instead.	**B2**
113	I am in favor of a fourth lane in each direction thru Oak Park as long as: It is accompanied by an extension of the CTA BLUE LINE to the outskirts of Cook County with parking garages at stations; the State of Illinois gives tax credits to those who live within 10 miles of their place of work; the City of Chicago increases the fees for downtown Chicago parking; the State of Illinois gives tax credits for economic automobiles (smaller user tax fee at purchase); noise walls are erected along the Eisenhower from Westchester to Oak Park; all expressways in Chicago are turned over to the Illinois State Toll Highway Authority so that those who choose to use them will be taxed on that use; and it is not dependent on taking additional right-of-way. It is not in the best interest of the driving public or Oak Park to maintain a bottleneck from Westchester to Oak Park.	**A1, A4, B2, C11**
114	I live in Oak Park and feel strongly that the Eisenhower Expressway should NOT have additional lanes added. The problem in our society is that we constantly want more and don't spend time figuring out how to get by with less. If we add more lanes, then more people will drive and we will be back to the same problem of increased traffic in the future. If people are forced to think of alternatives to driving (like using public transportation) because there is too much traffic, then they will. We need fewer cars on the road and better public transportation, not more lanes to accommodate more cars.	**B2**
115	Crossing the Eisenhower Expressway as a pedestrian in Forest Park is very difficult and dangerous. There is a high traffic volume from a number of locations at Harlem and Des Plaines and the Circle Avenue bridge has narrow vehicle lanes and narrow sidewalks adjacent to the roadway. Our main park is just along the south side of the Eisenhower Expressway. Forest Park desperately needs a pedestrian walkway over the Eisenhower at Beloit Avenue which is in the middle of our park. Please provide a safe way for pedestrians and bicycles to cross the Eisenhower Expressway in Forest Park.	**C3**

ID #	Proposed Alternative Comment	Disposition
116	The Eisenhower Expressway plan will have a significant and long-lasting impact on the area... well beyond it's projected completion sometime in 2017 or 2018! The planning for this project involves more than IDOT, as we know that the [Cook] DuPage [Corridor] Study and Oak Park Eisenhower Cap have included considerable input and studies into this projected development. In addition, other stakeholders are seeking involvement relative to the future applications in this corridor including freight rail, CTA, Metra, Illinois District 8 Park Districts. The study must include projected transportation demands considering: fall in peak oil production by 2020; 2020 - 2030 global oil demands relative to US fuel costs; projected "Green Generation's" increased dependency on public transportation; expected future capacity of CTA and/or Metra to meet increased commuter demands; evaluation of the similar US cities (i.e. Minnesota, Denver, Salt Lake City, St Louis, Portland) and the likely need for high-speed commuter rail; new 'auto ferry' approach (possible vehicle rail transport between I-290/I-294/I-88 and the south loop); rail or commuter termination within unused building spanning over Congress; convert I-290 to tollway to supplementary fund ongoing operation of public transportation alternatives; private business resource opportunities within the expressway; evaluation of the appropriate sound and environment barriers (avoiding the likes of the now disassembled "Berlin Wall" thru Illinois District 8 communities). There are many vantage points to look at this endeavor. At this critical planning juncture, it needs the leadership to encompass all stakeholder needs, and the vision to successfully merge these ideas.	**A4, B2, B9, B13, C7**
117	Adding more lanes to I-290 is not the answer. All that will do is add more auto traffic to this corridor in the long run. Extending public transportation further west along I-290 is a much better short and long term solution.	**B2**
118	I am opposed to an expansion of the Eisenhower. However, if the Eisenhower is to be widened, I believe any automobile expansion of the Eisenhower should be matched by an equal rapid transit CTA expansion to Hillside. I think the facilitation of automobile traffic will lead to greater urban sprawl which I consider to have a negative impact on the quality of life within our metropolitan region. I would prefer to see the Eisenhower capped and not widened. I believe the day of the car has come and gone. Detroit will be the next Tombstone. Highways will be the next Oregon Trail - just ruts across the landscape. Let's not burden our grandchildren with highways they will not use and will not be able to afford to maintain.	**B2**
119	As a long time resident of Oak Park, I would encourage IDOT to take a comprehensive look at the various options presented to dealing with the transportation needs of the Eisenhower corridor. I urge the study group to consider the various alternatives that have been put forward to simply recommending that the expressway be widened. I particularly urge the study group to support the westward expansion of the Blue Line along the expressway corridor. This option will be beneficial to all western Cook County suburbs and would promote the economic development of the area.	**B2**
120	Concerning the proposed Ike [I-290] land expansion project, we are concerned about the health issues during the construction period. Also we will lose our street, Garfield Ave, therefore, there will be more traffic on other streets. This doesn't seem like [I-290] a good idea, and there will be no advantage to people in our area (south of the Ike [I-290] and east of Harlem Ave). Only disadvantages and hardship during the construction.	**C10**
121	I was just wondering if there is going to be any coordination with CTA in regards to extending the Blue Line west. It seems as though it would be a given that raising money and community support etc. could all be done around both objectives. Also, if bringing the Blue Line west is going to happen perhaps we should consider underground subway system, with this system your property acquisition would be less. It may also speed up the process in that you would not have to hassle with some communities for land.	**B2, C9**
122	I am writing to express my opposition to any widening of I-290. As a resident of Illinois, my hope is that any future development will be with an eye to what our state and our country really need to succeed. Wider highways perpetuate our dependence on a car-based society. A car-based society relies on foreign oil and produces global warming - both things which make this country a frightening place for future residents. Instead of continuing the knee-jerk reaction of adding lanes because we have so many cars, we should take a careful look at what is fueling this need. Are more residents in far-lying suburbs driving daily into the city? How can we plan urban communities to better protect our resources while also helping our citizens. Better public transportation options are the wave of the future and Illinois risks being behind the times if we don't face this reality. As a former resident of Atlanta, I have seen that a city built of 10-14 lane highways built through unregulated urban sprawl, only continues to be clogged with traffic. If you add more lanes, they too will be clogged with traffic with no added benefit to commuters or those whose communities have been destroyed. As a resident of Oak Park, I am even more vehemently opposed to any widening of the Ike [I-290].Our historical homes and libraries and conservatories are national treasures. It will cripple a vibrant community to destroy this. The current Ike is enough of an eye-sore and pollutant. Why isn't there already a barrier wall separating the Ike from Oak Park to cut down on air and noise pollution? Why aren't trees planted on either side to further counter-act the ill-effects of the highway? If IDOT insists upon widening the Ike [I-290],they should consider these kind of options to make it more palatable. In addition, when looking at the current path of I-290 through Oak Park, it is obvious that any construction will impact the Blue Line. If more lanes are really the ONLY option, why not raise the Blue Line, creating a lane for cars underneath? Why not re-route the freight train line to the south of I-290 which is hardly ever in use to create another lane or two without destroying historic homes and the heart of a community? I urge you to act with an eye toward a sustainable future and a heart full of respect for the history and future of a vibrant town.	**B2, C9**
123	I have lived in Hillside for 30 years. I work right in the south loop. The solution seems simple. Move the ramps from the middle of the highway at Austin Blvd and Harlem Ave to the sides. Extend the Blue Line west, maybe as far as Lombard. Add lanes till there are 5 in each direction from the Circle to Wolf Road. Enforce the truck lanes and stop light [metering] on the ramps.	**A1, B2, C2, C6**

ID #	Proposed Alternative Comment	Disposition
124	As someone who lives in Oak Park and commutes using the I-290 I have first-hand experience with the traffic problems there. Expanding I-290 is not a viable long-term solution to the area's congestion problem. While it is true that a bottle-neck exists, where the expressway narrows from eight lanes to six, Oak Park is not the root cause of congestion on I-290. The only way to truly reduce congestion is to reduce the number of low-occupancy vehicles using the roadways at any given time. Some form of public transit is the solution. The six lane constriction of I-290 is not simply an Oak Park issue. The expressway is narrowed in this fashion for six miles between Austin Blvd and Mannheim Rd. Making I-290 wider in Oak Park will accomplish nothing other than a shift in the bottle-neck 1.5 miles and a great deal of destruction in Oak Park simply for being in the way. It solves nothing. Oak Park will loose hundreds of homes and the attendant property tax revenue, many businesses, and a public library. Seven bridges would need to be demolished and reconstructed causing a major disruption on major north/south arterial streets like Austin Blvd, Harlem Ave, Oak Park Ave and Ridgeland Ave. The negative consequences for emergency services are obvious. Five CTA station houses would also require reconstruction. All this and years of construction related traffic disruption for no solution. Fixing the lane issue would require a swath of demolition six miles long from Austin Blvd to Mannheim Rd across several municipalities including Oak Park, Forest Park, Maywood, and Bellwood. This would engulf homes, businesses, schools, parks, municipal buildings, and churches. The acquisition costs for theses properties would be staggering not to mention the permanent loss of tax revenue, and the costs required to replace public buildings. In addition, the relocation of hundreds of graves in Waldheim and/or Concordia Cemeteries would be necessary. The reconstruction of twenty-one bridges will also be needed. However the massive investment of public money, many years of construction and extremely worsened traffic, as well as the years of shutdowns or disruptions of CTA services between Des Plaines and Austin will ultimately accomplish very little but the construction of two terribly expensive expressway lanes. It would be a profligate waste of public funds that no government entity in Illinois can really afford. The pattern in other areas such as Atlanta, GA shows that simply building more and bigger expressways does little to solve traffic congestion problems. Any effort to reverse the eight-to-six lane bottleneck on I-290 will have very limited success at best and at a disproportionately great expense. Expanding I-290 will do absolutely nothing to address the very real congestion issues between Mannheim and Thorndale or Austin and the Loop where no bottleneck problem exists. Other expressways in the region without bottlenecks also suffer from severe congestion during peak use periods. In light of this, the six-lane stretch between Austin and Mannheim can hardly be the sole traffic obstacle of east-west travel. If the growth patterns of the region persists, then there will be even more vehicles on the road negating the benefit of an additional lane by the time such a project is completed unless there is some viable transit alternative to reduce the need for more roads to accommodate more low-occupancy vehicles. Express buses from outlying western suburbs to the city is one low cost alternative that would not require vast expenditures on new infrastructure and can be implemented very rapidly. Such buses would travel between major population/activity centers with very limited stops (e.g. Oak Brook Mall – West Point Mall – Maybrook Court – Loop). A proper study and survey of travel pattern would be needed to designed the best routes. However, any such routes must be active during peak travel times and should not add significant time to commuter's travel compared to driving by making excessive stops. Alternatively, extending the CTA Blue Line further west can serve a similar purpose at greater speed and capacity, especially if express services can be initiated that bypass most stops within Chicago. However the rail option carries with it significantly higher cost than bus routes, similar community impact construction issues, as well as jurisdictional and cost-sharing issues between Chicago and the suburbs an extended CTA rail line would service. Community impact can be ameliorated with a subterranean route, but at higher cost. In the end, IDOT must fully consider all possible transportation options and not focus exclusively on more and bigger roads. Further, there must be an openness to acknowledge that a new or bigger road is not always the best or only solution to traffic mitigation.	**A2, B15**
125	Please look to a public mass transit solution rather than more lanes on the Eisenhower. It is the right thing to do...reducing dependence on oil, creating less pollution and leaving more green space rather than paving more area.	**B2**
126	Regarding the proposed expansion of I-290, I hope that an extension of the CTA Blue Line will be a priority over adding new lanes. I would also like to request a safe bike lane for bicycle commuters. The Illinois Prairie Path ends at 1st Avenue. Why not extend it through to the Lakefront as part of your new plan? Traffic congestion is not solved by more lanes, only by more transportation choices. As a citizen of River Forest, I am affected by any changes to the I-290 corridor. As a bicyclist and commuter, I want public dollars spent of transportation options for all citizens of Illinois, not just able-bodied, wealthy private vehicle owners between the ages of 16 years and 80 years old. Please consider all transit options for all citizens.	**B2, C3**
127	The key component of any I-290 project is to add additional lanes. Why not eliminate the emergency lanes at bridges and expand the emergency lanes between (removing grass embankments) to accomplish this. This is very cost effective. Secondly, a second access ramp for east bound I-290 to I-294 S and I-88 is a must. Create one for I-88, one for I-294, there is plenty of room and could be done immediately.	**A1, C2**
128	Please, please, please make two of the following changes to the this roadway. 1) Widen to 4 lanes all the way to the Austin exit. 2) Change the exits at Harlem and Austin so that they flow from the right lanes and not the center. I've entered and exited those lanes hundreds of times and each time it is dangerous.	**A1, C2**
129	I am a new Oak Park resident who must travel daily to the far SW suburbs. Getting rid of the bottleneck between Wolf and Austin is my primary concern. Obviously, a broader view would dictate some of the public transport options that have been discussed. But the current situation is subtracting years from my life.	**A1**

ID #	Proposed Alternative Comment	Disposition
130	Dear IDOT, To combat the growing tensions over the Eisenhower Expressway, IDOT has thus far viewed the problem as a need for more capacity on I-290, and seeks to expand the highway. There are not sufficient reliable, safe, and affordable transportation options in the study area west of Forest Park. What was originally constructed with great foresight as the first multi-modal highway/heavy-rail corridor in the nation has since devolved into a single-mode corridor beyond the western terminus of the Blue Line in Forest Park. In the environmental community, however, several officials and organizations view the situation differently. In order to understand the problems that are currently present in the Eisenhower Expressway, the foremost issue to be addressed is that of the environmental injustices perpetuated against low to moderate income families. The noise, air pollution, and unsafe pedestrian environment that already exist along the highway will be exponentially increased, decreasing the quality of life for local residents. Conversely, those that will benefit from the addition of lanes to the expressway are those that are already wealthier, and live further away from the expressway. Instead, we recommend that public transit options be considered as an alternative to further highway expansion. The corridor is in desperate need of a safe, reliable, and economical transit option to decrease household transportation costs, reduce our nation's dependence on foreign oil, improve air quality, reduce greenhouse gas emissions, and promote public health. Any option that is accompanied by highway expansion undermines support for these critical needs. Much of the traffic on I-290 could be significantly reduced simply by providing an alternative between the Oak Brook area and the present terminus of the CTA Blue Line. Coupling such an extension with a decent transit option operating between Naperville, Oak Brook, and Schaumburg, while also implementing congestion prices on I-290 during peak periods, would significantly amplify the benefit. Location-efficient housing would become clustered around the new rail stops, decreasing the cost of housing and transportation for low-income populations. In addition to the negative effects felt by denizens of the local neighborhoods, the proposed highway expansion would have a host of negative environmental effects. An expansion of this type will directly contribute to global warming, through the burning of more fossil fuels. The reduced air quality that this will result in will reduce public health, and put a strain on Chicago's hospitals and health systems. I implore IDOT to further examine the benefits of an expanded transit system as an alternative to highway expansion. The environmental, human health, and general societal benefits will be present for years to come. Sincerely, Kate Galbraith Jacky Grimshaw	**B2**
131	Traffic on the Eisenhower Expressway increases between Hillside and Harlem. Efforts to address the problem must include smart transportation such as a multiple rider lane, a dedicated bus lane, and extending surface rail to the far western suburbs.	**A2, B2, B7**
132	There is no doubt the Ike [I-290] needs to be widened. All the work on the "strangler" had minimal impact. The ramps at Austin and Harlem need to be replaced as well. I do NOT wish expressway to be covered in Oak Park, as has been suggested. These dollars should be spent on the project as a whole.	**A1, C2**
133	I am a resident of Oak Park and I am writing to express my opposition to further expansion of the Eisenhower Expressway. More lanes of highway will not reduce congestion, but investments in mass transit will. We have a wonderful regional transit system serving the western suburbs. We should build on it by extending the CTA Blue Line to Hillside to provide a real solution to urban congestion and a reduction to the energy consumption that contributes to global warming.	**B2**
134	As a senior citizen who does not like to drive at night, I feel it would be more useful to many seniors as well as those without autos to have the CTA Blue Line extended thru the suburbs to Oak Brook shopping malls.	**B2**
135	Please place emphasis on increasing and improving rapid transit along the Ike [I-290] as an alternative to adding more lanes in the targeted area. History has proven that increasing capacity on roads quickly leads to having that new capacity filled. So don't add more lanes. Instead extend the CTA Blue Line farther out west, perhaps to Hillside if possible. And see if the existing tracks can be improved to increase speed, lessen noise, and ensure a smoother ride. The transit cars need to be improved as well - with more comfortable seats and better suspension. People will use the CTA more if riding on it was less uncomfortable. We are not cattle. Regarding the repaving of the Ike [I-290] planned for 2010, efforts should be made, if possible, to improve the pavement and traffic flow and light synchronization on the two principal alternate parallel routes, Roosevelt Ave and Madison St. Drivers would be much more likely to take these streets into/out of the city if they weren't so bumpy, if traffic lights were better timed, if there were better street lighting, and if police aggressively enforced the ordinances prohibiting double parking, lane changes without signaling, and similar Third World-like driving practices that now make driving on those streets so stressful and even somewhat risky. We are a First World country and people need to drive as if they live in one.	**B2, C5, C6, C10**
136	Regarding the I-290 study, I adamantly oppose expanding the highway. The expansion will have detrimental effects on the livability of neighborhoods affected by expansion including an increase in noise and air pollution a loss of important through streets adjacent to I-290. Moreover, it is unlikely that any possible expansion will reduce congestion. A better alternative would be to extend the CTA Blue Line tracks further west. This would allow for greater transit capacity and connect areas of disparate opportunities to one another. In particular, it would be useful in opening up quality job opportunities in the suburbs to low-income persons living in the City of Chicago. In an age where we need to build for sustainability and regional equity, IDOT should invest in smart growth. Extension of the Blue Line is much more sustainable and less destructive than widening I-290.	**B2**
137	Build a second deck.	**C8**
138	This is a comment regarding the I-290 Expressway study. I do not feel that expansion of the roadway would be at all beneficial. The "Hillside Strangler" study and expansion project only moved the congestion to another point. I seems better to consider extending the El or similar options further west and having a decent parking area at that end.	**B2, C11**
139	I suggest the Eisenhower be expanded by building up instead of widened.	**C8**

ID #	Proposed Alternative Comment	Disposition
140	I think that this project is a complete waste. There is no reason to expand the Ike [I-290]. It will have little or no affect on traffic and will just encourage more people to try to use it to get into and out of the city. The money should be used to provide viable alternative transportation for people to move back and forth from the outer suburbs into the city that is more sustainable for the economy, the environment and less disruptive of the community. The corridor between Manheim Rd and Austin Blvd is narrow and densely built up and has created a deep division in several of the towns it passes through including Oak Park and Forest Park. In the space of a city block of Oak Park that corridor includes 6 lanes of highway, two CTA train tracks, dedicated space for two more that could allow express trains to operate if the track was extended to west as a transit alternative, and three well-used freight train tracks. Retaining walls and narrow frontage roads for local traffic are all that separates the corridor from business and single- and multi-family homes in Oak Park. Moving entrance and exit ramps to the outside of this gap will put fast moving traffic right next to Oak Park homes and the local traffic creating dangerous conditions and even more noise than currently exists. There is no room for wide curving exit ramps to connect to Harlem Ave, Austin Blvd or Des Plaines Ave to name just a few. There should absolutely be no taking of additional land or demolition of buildings in Oak Park or Forest Park or elsewhere in the area under study. Whatever is done needs to be done fully within the existing corridor property and not destroy the adjacent communities by removing even more of the built fabric of the historic older suburbs so those who choose to live in the outer suburbs miles away from the center of the city can more easily reach their destination. People need to live closer to the places they need to reach or live with long commute times.	**B2, C2**
141	I would urge IDOT to place the highest possible priority on an extension of rapid transit- high speed rail- as the primary solution to our region's auto commuting dilemma on the Eisenhower. We believe adding lanes to the expressway is a short sighted, ill-fated approach.	**B2, B13**
142	I would like to express my strong opposition to adding additional lanes to the Eisenhower Express between Mannheim Rd and Cicero Ave. Past experience demonstrates that such a strategy is self defeating. Improvements to public transit are a more cost effective way to reduce congestion, improve access to transportation services and avoid the public health and other environmental problems associated with increasing automobile traffic. Extending public transit also provides an opportunity to reduce our reliance on foreign oil and the threats of global warming. The extension of the Washington D.C. transit system to the suburban metropolitan area with its remote parking provides a compelling example of the benefits of a modern public transit system. In addition to taking thousands of cars off the road each day the transit stops have become centers of economic development. I urge IDOT to reject obsolete highway strategies and use the I-290 corridor to develop a modern public transit option to meet the region's transportation needs.	**B2**
143	Why not create a two level expressway. A double decker approach would increase traffic flow, shield the road from snow and other weather, allow for construction repairs and not require a substantially larger footprint. It could be built with pre-stressed concrete(flexicore)and this would allow for rapid construction while utilizing superior materials and a much more efficient process. It would also create a sophisticated and advanced look that would positively impact the perception of Chicago.	**C8**
144	This is long overdue. Can the I-290 eastbound to I-294 southbound ramp be included? Backups are notorious as far back as Rte 83.	**C2**
145	For years, my husband has complained as we go from Harlem Ave to Austin Blvd about the control Oak Park has to create unsafe conditions for thousands of people. We definitely think that the "Ike" [I-290] should be widened to 4 lanes all the way! The last time the Hillside Strangler was attacked, I was "strangled" during construction, for I worked at Proviso West HS--and we all could have predicted that the bottlenecks were not going to leave--only to move a bit east. Let's not have such a lot of money spent on something that's NOT a solution again!	**A1**
146	Regarding the IDOT discussion of widening I290 between Cicero Avenue and Manheim Road: Adding lanes won't reduce traffic congestion. Illinois spent $140 million to fix the Hillside Strangler, yet travel time remained virtually unchanged. If we were to build all the lanes traffic engineers say is necessary to "solve" congestion, the Ike would be 12-14 lanes wide. As long as they still have to merge into two lanes to get onto I90/94 or two lanes on Congress, all that will be accomplished is moving the bottleneck farther East. The congestion will continue. More highway lanes means more cars, more noise, more air pollution, property acquisition, and more global warming pollution. Extending the CTA Blue Line to Hillside, and providing parking for commuters near the stations, is a better solution. It would increase mobility, solve congestion problems, and improve our communities.	**B2, C11**
147	I am opposed to expanding the Eisenhower Expressway. I believe that we should extend the Blue Line train to increase the transportation "bandwidth".	**B2**
148	Adding highway lanes has proven to be an ineffective means of reducing traffic congestion. The totality of transportation needs and options of the Cook-DuPage Corridor [study] must be considered. Extending the CTA Blue Line west has to be the top priority. Building new roads is a 20th century solution to the transportation and ecological challenges of the 21st century.	**B2**
149	Expanding the Eisenhower is a short-term solution to a long-term problem. We need to think into the future expanding the El and public transport is the way to go on this issue, not adding more cars, more carbon and frustrated people grid locked in traffic.	**B2**
150	I would like to state that I do not believe widening the Eisenhower Expressway between Cicero Ave and Mannheim Rd is a good solution to the current traffic problem. Rather than increase the capacity we would be better served by reducing the traffic that passes through this area. The extension of the CTA Blue Line further west is more responsible from a global and environmental aspect. The United States needs to develop a mass transit program and teach people the value of it, choosing to expand the CTA rather than using up more land and adding to pollution by accommodating more traffic is a more forward looking and longer lasting solution.	**B2**
151	I do not want anymore pollution or noise by my house which is two blocks from the expressway. Expansion of the expressway only promotes automobile travel. In a few years the expressway will be crowded again. Where do you stop? Why not just build a ten lane expressway? Please leave the expressway as it is currently or expand public transportation.	**B2**

ID #	Proposed Alternative Comment	Disposition
152	This letter presents the views of the Oak Park Environmental and Energy Commission ("Oak Park EEAC") regarding IDOT's current review of its options for reducing congestion on the Eisenhower Expressway. The Oak Park EEAC believes that the current congestion on the Eisenhower imposes unacceptable environmental and economic costs on Oak Park and the other communities that border the Eisenhower, and we urge IDOT to address this problem. But the only environmentally responsible way to reduce congestion is by expanding rail service along the Eisenhower west to Oak Brook. Whatever the other comparative costs and benefits of adding traffic lanes rather than expanding rail service, when it comes to the environment, rail is the only responsible option. The Oak Park EEAC is a citizen commission established by ordinance in 1997 to advise the Village of Oak Park Board of Trustees on energy and environmental issues in the Village of Oak Park. The Commission is appointed by the Board of Trustees. The Oak Park EEAC is submitting its position to IDOT because expansion of the Eisenhower Expressway would have a significant negative impact on the environment in Oak Park. Oak Park has approximately 50,000 residents and is one of several communities that are bisected by the Expressway. Many Oak Park residences and businesses are located within a ¼ mile of the Expressway. These residences and business would be most directly affected by an expansion of the Eisenhower, but the negative environmental consequences of an expansion would ripple throughout Oak Pak, endangering the health and quality of life of the entire community, imposing additional economic costs (most obviously for additional health care) and directly undermining the Village's investments in programs to reduce greenhouse gas emissions and improve air quality in the Village. We encourage IDOT to review the December 2002 "Report on the Potential Impacts of the Proposed Eisenhower Expansion" prepared by the Oak Park Eisenhower Citizens Advisory Committee. The Report contains substantial detail about the environmental impact of expanding the Eisenhower. The goal of this letter is not to replicate that analysis, but to emphasize the primary quantifiable environmental benefits of additional rail – reducing green house gas emissions and harmful pollutants. [Continued] [Continued] First, transporting commuters by rail, rather than bus or car, will reduce pollution and greenhouse gas emissions. According to the 2009 American Public Transportation Association ("APTA") Fact Book, each year public transit use in the United States reduces C02 emissions by 37 million tons from what they would have been if public transit commuters had commuted by automobile. While putting commuters who would have travelled by car into a bus will have a positive environmental impact, most buses burn diesel fuel while CTA trains do not, and the electricity needed to operate CTA trains can be generated by sources other than fossil fuels. Furthermore, even if adding lanes were to reduce some pollution by reducing congestion, prior experience strongly suggests that the number of vehicles on the road will quickly increase, offsetting any such gains. By contrast, adding rail will inevitably take cars off the road, which will necessarily reduce pollution. Second, transporting commuters by rail will save energy. The APTA estimates that each year, use of public transit reduces annual fuel use by the equivalent of 4.2 billion gallons of gasoline. Third, adding additional lanes to the Eisenhower will have a significant negative impact on air quality and, consequently, public health. The additional emissions produced by additional vehicles will increase the exposure of Oak Park residents to diesel soot, ozone, nitrogen oxides, carbon monoxide, hydrocarbons and other carcinogenic substances, not to mention subjecting them to increased noise pollution. This increase in noxious emissions will not only reduce the quality of life of citizens who live along the Eisenhower, it will increase health care costs to treat the respiratory and other ailments that result from these pollutants. For example, the Clean Air Task Force predicts that in 2010, diesel fine particles will cause 540 premature deaths, 707 non-fatal heart attacks, 321 cases of chronic bronchitis, 11,459 asthma attacks, and 67,603 work-loss days in Cook County. The Clean Air Task Force ranks Cook County 17th out of 3,019 counties in the United States in terms of risk from diesel soot. Expansion of the Eisenhower will impose a number of other costs on the Village of Oak Park, and it is far from clear that expansion will produce any long term benefits in the way of reduced commuting times. Indeed, given the costs outlined above, there is a significant risk that choosing to expand the Eisenhower rather than adding rail will have a negative economic impact on the region. For all these reasons, the Oak Park EEAC strongly urges IDOT to solve the congestion problems on the Eisenhower by adding rail, not by adding traffic lanes.	**B2**
153	If you can do what they have done for I-294 and I-80/I-90 on the Eisenhower especially between Hillside and just past Austin Blvd going east and approaching Austin Blvd going west from Chicago you would make the Chicago area expressways the best in the country.	**A1, A4**
154	I'd like to tell you that I'm totally against the widening of the Eisenhower Expressway. We have a two flat in Oak Park that has been in the family since 1917 and four and soon five generations have been raised in that house. By widening the expressway it puts our house in jeopardy. It means more cars, more fuel, more noise, and more pollution. I've been told that the Conservatory would be torn down and the park would become much smaller. Why not expand the Blue Line and spend the money improving public transportation.	**B2**
155	I have lived in Oak Park for over 30 years. Please do not expand the Ike. Extend the EL.	**B2**
156	GET CARS OFF ROADS...RUN HI SPEED RAIL TO FAR SUBS LEARN FROM OTHER COUNTRIES	**B13**
157	I have gone to the meetings and I looked at the maps _____ on google. It makes no sense to just widen a few miles of the Ike. All that will so is add to the congestion! What does make sense is to use that money and extend the Blue Line at least to Maybrook Dr. and then to I294 with the ultimate goal of Oak Brook and _____ to the new ring Metra communities from the North. When I moved to this area in 1970, the commute from the Western suburbs was already a mess just a few years after being built. We must take a different approach to public transportation. Good, clean, safe trains are a much better use of our tax dollars! P.S. Website not working.	**B2**
158	Expanding the Eisenhower is a short term solution to a long-term problem. As a concerned resident who lives directly beside the already existing road I am against expansion, it will destroy our community. A long term solution would be to extend to El-Line and better public transport.	**B2**
159	To have exits all major streets on 290. To widen lanes near Oak Park and Maywood to lessen bottleneck.	**A1, C2**
160	Current Conditions Problems: 1. Too much traffic congestion through the corridor, especially through Oak Park. 2. Over pass bridges in Oak Park are in poor condition, are unsafe, and now-ADA compliant, not wide enough for traffic flow. 3. The negative environmental impact, of poor air quality and extremely excessive noise, from the expressway ditch b/w Austin and Harlem. Solutions: CAP the Eisenhower through Oak Park; extend the Blue Line to Oak Brook; Add a BRT Lane. Do all 3.	**B2, B7, C7**
161	Yes there is congestion, but I worry that widening the Ike will only create more traffic. Please consider either extending the blue line buying a rail line from Canada line and running Metra trains. We need alternatives.	**B2, B9**
162	I am strongly focused in extending public tranportation rather than widening the Eisenhower. Or use land used by rail instead of tearing down houses	**B2**
163	I was a long-time resident of Westchester, now living in Darien. I still use I-290 quite often for business and pleasure and find it frustrating day and night to get through this area of the highway. On an even more personal note my brother was killed in 1988 after his eastbound car stalled on the right side of the highway while approaching Harlem Ave. He attempted to cross the highway on foot to get to the Harlem Ave ramp and was struck by a car in the left-hand lane. That ramp situation as well as the ramp at Austin Blvd I would hope could be moved to the right side as part of this project. While my brothers situation was unique I have always found it uncomfortable trying to enter or exit at those ramps in heavy traffic, maybe because they are not the norm. I don't know if accident statistics support my concern but if so please consider the possibility of moving those ramps.	**C2**
164	Please expand I-290! sooner rather than later.	**A1**

183	(Map Post-it Note) North bound tollway at West bound I-290 entrance from Park and Ride.	**A4**
184	(Map Post-it Note) New location for high-speed rail Park N' Ride from Hillside to the old post office building on Congress and Clinton.	**B13**
185	(Map Post-it Note) South bound tollway exit and East bound 290 exit to high- speed rail Park N' Ride.	**B13, C11**
186	(Map Post-it Note) Add parallel track for high speed rail (along rail between Darmstadt Rd and I-290).	**B13**
187	(Map Post-it Note) South bound tollway and West bound I-88 entrance from new high-speed rail Park and Ride.	**B13, C11**
188	(Map Post-it Note) Make I-290 a tollway between Hillside and downtown to finance high-speed rail and support of it's operational costs.	**A4**
189	(Map Post-it Note) Congestion pricing to encourage mode shift. All lanes tolled should be tested.	**A3, A4**
190	(Map Post-it Note) Blue Line stop at 25th Ave.	**B2**
191	(Map Post-it Note) 1. Extend Blue Line as far West as possible. 2. Ramp entrances should be on the right side. 3. There should be 5 lanes on each side. 4. larger exit signs.	**A1, B2, C2, C6**
192	(Map Post-it Note) Blue Line stop at 1st Ave, Maywood.	**B2**
193	(Map Post-it Note) Extend Forest Park "L" to Maywood and further.	**B2**
194	(Map Post-it Note) Blue Line must go further West than Maybrook---to Oak Brook area.	**B2**
195	(Map Post-it Note) Look at intermodal facility at 1st Ave by extending Blue Line, moving shops and bus terminal.	**B2**
196	(Map Post-it Note) Blue Line park & ride (along Maybrook Dr in Maywood).	**C11**
197	(Map Post-it Note) Blue Line park & ride (west of 25th Ave at Prairie Path).	**B2, C11**
198	(Map Post-it Note) Blue Line extension and consistent with the Maywood Comp. Plan	**B2**
199	(Map Post-it Note) Consider BRT through corridor.	**B7**
200	(Map Post-it Note) BRT with HOV without barrier separation is ill-advised.	**A2**
201	(Map Post-it Note) Expand	**A1**

ID #	Proposed Alternative Comment	Disposition
202	(Map Post-it Note) Expand roadway 4 lanes.	**A1**
203	(Map Post-it Note) Build a double-decker expressway.	**C8**
204	(Map Post-it Note) Build double-decker for express traffic over present railroad tracks.	**C8**
205	(Map Post-it Note) Expand at the 1st Avenue area. Traffic always bottlenecks in this area.	**A1**
206	(Map Post-it Note) Emergency lane needed for emergency vehicles going to Loyola (1st Ave.)	**A1, C11**
207	(Map Post-it Note) Muni Plans along IHB, E.G., LaGrange Park, Broadview, etc., anticipate inner circ to Blue Line @ I-290/25th. How will alternatives contemplate these benefits.	**B10**
208	(Map Post-it Note) Project should contemplate accessibility benefits @ IHB--inner circ for O'Hare/Midway job access.	**B10**
209	(Map Post-it Note) I like it the way it is, but bike lanes might be nice.	**C3**
210	(Map Post-it Note) Add bicycle lanes into corridor	**C3**
211	(Map Post-it Note) Connect the Prairie Path to a bike route into the loop.	**C3**
212	(Map Post-it Note) Restore ____ Prairie Path (Old Elgin) Chicago _____.	**C3**
213	(Map Post-it Note) 1) Traffic timing issues for north ramps at 1st Avenue cause congestion. 2) District courthouse is considering expansion. 3) Increase mobility to/from courthouse pedestrian/public transit.	**C3, C5, C6**
214	(Map Post-it Note) 25th Avenue ramp backs up causing traffic problems for business along Beach Street.	**C2**
215	(Map Post-it Note) Reconstruct Roosevelt Rd in advance as alternative during construction.	**C10**
216	(Map Post-it Note) More public transportation, especially coming in from DuPage Co. is very important.	**B2**
217	(Map Post-it Note) Please save our real estate. Extend the Blue Line (surface or subway) to Oak Brook.	**B2**
218	(Map Post-it Note) Extend CTA Blue Line to DuPage County	**B2**
219	(Map Post-it Note) Have the Green Line extend. Consider bicycle lanes to the community.	**B5, C3**
220	Public transportation is the one solution	**B2**
221	(Map Post-it Note) Consider BRT solution through corridor	**B7**
222	(Map Post-it Note) Cost for BRT must include new lanes, etc. BRT can't exist without them.	**A1, B7**
223	(Map Post-it Note) How will alternate modes of transportation like bike lanes and bus and train lines be added or extended within the context of this plan. I fear the only thing considered will be widening I-290.	**B2, C3**
224	(Map Post-it Note) Consider HOV lanes through the corridor.	**A2**
225	(Map Post-it Note) To reduce traffic on I-290 and not just move it downstream past Cicero= the extension of the Blue Line Westward (possibly to Oak Brook). Also add park and rides in westward villages.	**B2, C11**
226	(Map Post-it Note) BRT is a placeholder for rail. The corridor is already dense enough for rail, so a placeholder is a waste of $.	**B2**
227	(Map Post-it Note) This plan is myopic. Instead think of a rail-west with multiple routes.	**B2**
228	(Map Post-it Note) Waste of $ to build more lanes. Spend $ on public transit.	**B2**
229	(Map Post-it Note) Bring the Cta under the roadway.	**C9**
230	Pave it over and add rail. Electric rail (freight and passenger) .	**B10**
231	(Map Post-it Note) Do not add HOV lanes. Put in extension of Blue Line.	**B2**
232	(Map Post-it Note) Put trains underground and run new lanes on top.	**C9**
233	(Map Post-it Note) Can CTA be extended West-- with parking lots out west, ride train into downtown.	**B2, C11**
234	(Map Post-it Note) Extend Blue Line further west.	**B2**
235	(Map Post-it Note) The extension of the CTA Line would be a better solution to the problem . Yes to the Oak Park Cap.	**B2, C7**
236	(Map Post-it Note) Extend Blue Line to Oak Brook. Do not add HOV lanes.	**B2**
237	(Map Post-it Note) I live in Oak Park six houses south of I-290, and I oppose the additional lanes. Expansion of public transportation is the answer--this will negatively impact the entire neighborhood and the investment I have made in my home-- No additional lanes!	**B2**
238	(Map Post-it Note) Extend rail service to Oak Brook and N/S to O'Hare.	**B1, B2**

ID #	Proposed Alternative Comment	Disposition
239	(Map Post-it Note) Blue Line to Yorktown in Lombard/Oak Brook/Downers Grove.	**B2**
240	(Map Post-it Note) Concentrate on light rail. Blue Line to Yorktown.	**B2**
241	(Map Post-it Note) If Blue Line is extended into DuPage county, do not run alignment next to expressway.	**B2**
242	(Map Post-it Note) Local traffic only. Replace highway with electric rail, freight on flat beds to Harlem or Cicero or Circle only. Passengers use CTA.	**B2, B10**
243	(Map Post-it Note) Extend Blue Line at least to Oak Brook (IL 83) or Lombard (Highland Ave).	**B2**
244	(Map Post-it Note) Make El a subway.	**C9**
245	(Map Post-it Note) Extend CTA or add Metra. Do not widen Ike.	**B2, B10**
246	(Map Post-it Note) Extend Blue Line to Oak Brook.	**B2**
247	(Map Post-it Note) Extend entrance ramps. Increase red light by a minimum of five seconds.	**C2, C6**
248	(Map Post-it Note) Build a pedestrian/bike bridge over the Ike at Beloit for access to park.	**C3**
249	(Map Post-it Note) Move ramp and aid traffic flow	**C2**
250	(Map Post-it Note) Make Austin Blvd and Harlem Ave right exits. There is room to do this without adding lanes or taking land.	**C2**
251	(Map Post-it Note) Move exit/entrance ramps to right side of lanes in Oak Park for safety.	**C2**
252	(Map Post-it Note) Place several "fat bridges" across I-290 to add open space and re-link several neighborhoods.	**C7**
253	(Map Post-it Note) Keep the ramps on the interior of I-290.	**C2**
254	(Map Post-it Note) Minimize land taken for off ramps at Harlem. Increase rail to the west.	**B2, C2**
255	(Map Post-it Note) Reconstruct the Harlem Ave. interchange as a traditional diamond interchange.	**C2**
256	(Map Post-it Note) The pedestrian bridge has all the appeal of a minimum security prison.	**C3**
257	(Map Post-it Note) Remove center lane merges [Austin Blvd, Harlem Ave].	**C2**
258	(Map Post-it Note) Lower R.R. tracks as much as much as possible to avoid raising crossroad bridges.	**C11**
259	(Map Post-it Note) Ped. access of EL on Harlem requires crossing a very busy road. Can this be made safer?	**C3**
260	(Map Post-it Note) Blue Line train station entrance is not safe for pedestrians crossing I-290 on and off ramps at Harlem Ave and Austin Blvd.	**C2**
261	(Map Post-it Note) We need bike lanes, not more car lanes so local commuters can bike downtown safely.	**C3**
262	(Map Post-it Note) Harrison frontage between Harlem and East Ave. is only 1.5 lanes wide. Dangerous for parking or two-way traffic. (See similar comment(#32) for Garfield)	**C10**
263	(Map Post-it Note) Garfield frontage road between Home Ave. and Austin is only 1.5 lanes wide and dangerous to park or drive. (See similar comment (#30) for Harrison)	**C10**
264	(Map Post-it Note) There needs to be a stop sign here on the north side of the bridge @ Circle due to heavy pedestrian traffic by the parks.	**C6**
265	(Map Post-it Note) Oak Park -- Widen the curb cuts and sidewalks for pedestrians at the Harlem Ave. off and on ramps. Much too narrow now.	**C3**
266	(Map Post-it Note) Sidewalk is very pedestrian unfriendly. Roadway is also too narrow to accommodate busses and ____ loading and unloading at CTA stations.	**C3**
267	(Map Post-it Note) See example of Oak Park, Michigan in terms of running expressways through communities without physically dividing them.	**C7**
268	(Map Post-it Note) Extend Prairie Path east to link up with Columbus Park.	**C3**
269	(Map Post-it Note) Jackson Blvd., bikes and pedestrians only. Connect to Prairie Path and Columbus Park.	**C3**
270	(Map Post-it Note) Partial Cap @Oak Park Ave/I-290--Reconnect business district.	**C7**
271	(Map Post-it Note) (Map Drawing) Cap I-290 from Home Ave. to East Ave. for new straight connection to East-West	**C7**
272	(Map Post-it Note) Either have CSX use their tracks or give them up to make room.	**C11**
273	(Map Post-it Note) Cantilever street on north side. Bump over on south side. Do not remove any more houses.	**C11**
274	(Map Post-it Note) Make it toll road $40 minimum.	**A4**
275	(Map Post-it Note) Look at one-way couples on frontage roads.	**C10**

ID #	Proposed Alternative Comment	Disposition
276	(Map Post-it Note) Meet with local communities impacted by the study. Extend Blue Line	**B2**
277	(Map Post-it Note) Move ramps to aid traffic flow.	**C2**
278	(Map Post-it Note) Don't switch ramps to right--use more effective metering.	**C2**
279	(Map Post-it Note) Re-design left exit/enter ramps in Oak Park.	**C2**
280	(Map Post-it Note) Lengthen on-ramps for rush hour traffic.	**C2**
281	(Map Post-it Note) Reconstruct westbound Austin Blvd interchange such that exit and entrance ramps depart and enter from westbound I-290 right lane.	**C2**
282	(Map Post-it Note) Get rid of lane drop westbound at Austin Blvd and all left hand ramps (Austin Blvd, Harlem Ave).	**C2**
283	(Map Post-it Note) Keep the ramps on the interior of I-290.	**C2**
284	(Map Post-it Note) How about building a fly over ramp to avoid the congested area.	**C11**
285	(Map Post-it Note) Provide bus space on bridges where there are rapid transit stops.	**C5**
286	(Map Post-it Note) This ramp catches motorists off guard. Left turn only w. four lanes to 3 lane reduction.	**C2**
287	(Map Post-it Note) Provide ample space for long semi-trailer trucks wanting to enter the Eisenhower or limit trailer length and enforce.	**C2**
288	(Map Post-it Note) Move all entrances/exits to right side of the road.	**C2**
289	(Map Post-it Note) Put CTA below ground.	**C9**
290	(Map Post-it Note) Expand public transit options. Do not add lanes.	**B2**
291	(Map Post-it Note) Extend rail service to Oak Brook.	**B2**
292	(Map Post-it Note) Need to acquire railroad property for moving CTA to the south and add lanes.	**A1**
293	(Map Post-it Note) No additional lanes-- Increase Blue Line track. No cap!	**B2**
294	(Map Post-it Note) Be more visitor friendly by providing many large signs for streets.	**C6**
295	(Map Post-it Note) Have more signs ahead of arriv[ing] at exits for Harlem & Austin	**C6**
296	(Map Post-it Note) Cars sitting in traffic pollute. Need more lanes.	**A1**
297	(Map Post-it Note) Need 4th lane - managed lane with transit - as part of regional managed lane network.	**A2, A3**
298	Would moving the 4-3 lane contraction to a straight road segment (here?) result in less congestion?	**A1**
299	(Map Post-it Note) Add lanes! Keep it in the ditch!	**A1**
300	(Map Post-it Note) Cap on partial cap @ Austin/I-290. Connect Columbus Park with Barrie Park.	**C7**
301	(Map Post-it Note) Blue Line station entrance at Harlem unsafe with pedestrians crossing I-290 on and off ramps.	**C5**
302	Try SPUI [single-point urban interchange] at Austin Blvd and Harlem Ave.	**C2**
303	Oak Park EEC letter, add rail, no adding of traffic lanes.	**B3**
304	Commuter trains should be extended to at least Hillside (the former quarry landfill could be a terminal) or Berkeley (the air space above the Proviso Rail Yards could be a terminal and connection to Metra) It would relieve some of the highway traffic. Adding lanes would of course reduce congestion.	**A1, B2**
305	Intersection saftey at Austin and Railroad south of IKE	**C10**
306	There should be a lane increase between Mannheim and Cicero in both directions, but especially the inbound. No boutique in Oak Park is more important than the precious time of thousands of commuters who are bottlenecked in this area each and every day.	**A1**
307	The obvious solution is to add a lane from Austin to Mannheim. Whoever design I 290 to narrow at Austin must have had the foresight of a rock. Getting rid of that ridiculous bottleneck would vastly improve the flow in peak hours.	**A1**
308	Carpool lanes will not solve any of the problems on the Eisenhower. I doubt that many drivers would pay attention to the restrictions. I think that the CTA lines should be extended at least to Oak Brook.	**B2**
309	Expand the CTA Blue Line west and upgrade the rail lines. Leave the Eisenhower itself alone. We need to lessen our dependence on cars and move to forms of transportation that benefit the environment and do not destroy the community.	**B2**

ID #	Proposed Alternative Comment	Disposition
310	As a resident of Oak Park and one living a block away from I-290, I am writing to express my extreme opposition to any attempt to expand the Eisenhower freeway without a proper, independent and honest environmental impact study. This study should not only look at the deposition of highway contaminants up to 5 blocks away from the freeway's proposed site of expansion, but also the immediate impact of the expansion on air quality in the surrounding area. Additionally, a cost benefit analysis should be done to compare the cost of the expansion over the cost of more environmentally and socially sound alternatives, such as expanding the CTA service. Finally, this analysis should also accurately reflect the true value of HOV lanes (many studies show them to be ineffective) and consider the cost of the decrease in quality of life, property values, and the increase in potential diseases due to increase pollutants in the air and ground. I believe that a fair analysis will show what Oak Park residents have been saying all along, that there are far better alternatives to improve transportation along this corridor without compromising people's health and the environment.	**B2**
311	It is foolish to expand the Eisenhower, given that we are in a crisis regarding availability of oil and of global warming. The only sensible solution involves rapid transit and the Blue Line.	**B2**
312	Please, please provide a safe bicycle path that will run along the new eisenhower expressway. There are many bikers, runners, etc...that would utilize this route into the city, especially from Oak Park and nearby suburbs. The current Augusta bike path is not a safe route and is pretty much a joke - too many gangbangers, crazy drivers and pot-holes. It would be irresponsible not to implement a healthy lifestyle and safe route into the city for the 21st century. Now is the time and Chicago can be a leader in promoting "green" urban development.	**C3**
313	Please consider adding a "green" piece to this project...a separate,protected from traffic, bicycle lane, running parallel to the expressway. This is a wonderful opportunity to provide communities with an alternative method of transportation.	**C3**
314	I would like to see a bike lane incorporated into this project. It's a sensible, green, twenty-first-century thing to do. If the el can exist alongside traffic, so can a bike path. Please consider allowing commuters an alternative means to transportation that reduces congestion and reliance on foreign oil.	**C3**
315	I can not believe in this day and age we are not planning for alternative transportation choices which include biking to work or a day in the City. Come on people and get wtih the times and add a bike/walk path along the Eisenhower expressway while you still have the opportunity to still make this an option.	**C3**
316	The expressway should be rebuilt with the future in mind. Just expanding the size is not what will help the general public. In London you cannot drive in the downtown area without paying a fee. The same thing is going to happen in Chicago so we do not need more cars & trucks going into the city. A much better idea is to expand the public transportation to reflect the growing population. It should be expanded to the suburbs so they will come to the City but not clog it up with vehicles. Better and safer service with Trans (ELS) going out to Aurora and Dekalb & other Surburs on all areas North,South,Southeast & West is the ideal situation, not more vehicles. It will also help keep polution down.	**B2**
317	How about a bike/running lane? Those close to the city could use their own power to get there safe and fast. Perfect time to move toward a more environment responsible plan. Not to do so would be a great mistake.	**C3**
318	The Hillside strangler is worse than ever, especially after the huge project that was supposed to fix it. What is being done to have a set number of lanes the entire length of the highway - i.e. 4 or 5 lanes so the 4 and 5 lanes of traffic downtown and out in the suburbs do not need to jam into 3 lanes in the strangler area.	**A1**
319	It is important to add the idea of "bike paths" to the initial design for the Eisenhower Expressway project. Chicago needs to think more "green". Otherwise, we'll be a city that is always repairing bad decisions.	**C3**
320	I travel the Eisenhower from Wolf Road through downtown Chicago every weekday because public transportation is too difficult to get me to the north side of Chicago. I'm not the first one to register this observation, but the narrowing of the Ike through Oak Park is nonsensical. Let me echo the sentiment of thousands: Add a fourth lane all the entire length of the Ike. Thank you.	**A1**
321	Instead of adding additional lanes to the Ike [I-290] at Austin, your should seriously consider expansion of the CTA Blue Line west into Maywood and Hillside and upgrade the rail lines to accommodate transportation demands.	**B2**
322	Instead of expanding the Eisenhower, the State should re-allocate the funds to extend the CTA Blue Line to Maywood and Hillside. Expanding the Eisenhower is at most a temporary fix. In time more drivers will use the extra lanes causing those lanes to be overcrowded, just as the added lanes intended to solve the "Hillside Strangler" already are. The environmental impact of extending the El is much less than adding lanes to the Ike.	**B2**
323	We need a bike path into the city!!!!!!! It must be incorporated into this plan or we again will be missing out on a golden opportunity to be GREEN!!!!	**C3**
324	I strongly support adding a fourth lane to the Eisenhower Expressway between Austin Blvd and 25th Ave. The fourth lane would correct a design flaw that has existed in the highway since it was built 50 years ago. The daily traffic gridlock caused by this design flaw has a huge economic and environmental cost to our region and even the national economy. The costs of having tens of thousands of cars and trucks caught in the gridlock include a huge loss of productivity, additional pollution and a waste of fuel. The cause of this gridlock is the narrowing of a busy highway from four to three lanes. It is time for the obstructionists to stand aside and let the state add the fourth lane. I believe that there are options to add the fourth lane in Oak Park without widening the existing trench through the village. I hope that the project can be completed without taking any additional, or only very minimal land, in Oak Park. I am also opposed to the fourth lane being only a HOV lane. We do not have HOV lanes in the region, and I see no reason to require that the new lane be HOV. I work in downtown Chicago and ride the Metra from Oak Park on most work days. I do support improvements to public transportation, including looking at extending the Blue Line to Hillside or Oak Brook and expanding service on Metra. But first things first-widen the Ike [I-290].	**A1, B2**
325	Add a lane both eastbound & westbound from Austin to Mannheim.	**A1**
326	It is vital to the transformation of our urban area to have a green and cycling safe connection linking, the near suburbs to downtown. I am a regular bicycle commuter from Oak Park into the Loop. Safety is a huge issue.	**C3**
327	With a critical need to improve physical health, lower carbon emissions and alleviate congestion, we must integrate alternative transportation, like safe cycling and pedways.	**C3**

ID #	Proposed Alternative Comment	Disposition
328	What happened to the proposals which were extensively studied to partially cap the IKE in Oak Park?? Oak Park does not need more lanes widening the IKE. It is plenty disruptive now!! In the 50's the community successfully blocked the exits at Ridgeland Ave. Later the idea of tunring Ridgeland into the Crosstown Xway was shot down along with the whole extreme disruption of the Crosstown route elsewhere..fortunately. The metro area should not have more traditonal expressways - think of European Cities defaced and destroyed by what has taken place in the US - rapid transit must be improved. Build another xway or lane and it will be clogged in no time. I am an 50 year Oak Parker residing on block adjacent to IKE - anmd a cyclist - so would appreciate accomodations in the future for cyclists. Riding from Oak Park downtown to the Lakefront is quite a challenge..no bike lanes, bike lanes which end, etc. Thanks for the chance to comment.	**C3**
329	We are not in favor of the expansion of the Eisenhower Expressway. We would like to see public transportation (rail) expanded instead.	**B2**
330	With everything that we now know regarding automobiles and their impact on the environment, there should be some kind of option for bicycles included in updated version of the Eisenhower. It would add little to the cost and greatly enhance the lifestyle for many Chicagoans. Thank you for listening.	**C3**
331	Has anyone thought of just putting another highway on top of the Eisenhower highway? Please do not cap the Ike. Oak Park should think about selling the property south of the expressway to Berwyn. That way there wouldn't be that seperation problem that Oak Park officials seems to worry about.	**C8**
332	Our concern is the taking away of private property in the communities along the expressway. Our suggestion is to go green and expand the El line further west.	**B2**
333	After years of suffering with the bottleneck of the Eisenhower from Austin to Mannheim, hopefully they will finally widen the highway to what it should have been all along 4 lanes each way!	**A1**
334	I strongly object to the widening of the Eisenhower Expressway. Studies show that widening highways creates more of a demand and increases the numbers of cars. Also, it would take land away from my town, Oak Park. We should put the money into Rapid Transit.	**B2**
335	With this lastest re-paving fiasco: Of which it seems like all of us that go west just got through with stuff and here we are again! Why dont we/you do the real repair on the IKE which is the ebtrance and exits from the left lanes from Central, Harlem, etc and.....the lanes narrow by a lane! Whomever designed the left hand enter and exit on top of a lane reduction - should have to drive the IKE in both directions every day for at leat 5 times per day! I hope whomever is reading this has a sense of humor but it is rediculous! Drivers have a tough time merging to begin with and then when you let them on and off to the left!???!!! That is where we should be working and investing! I also do NOT think I am alone on this!?	**C2**
336	With so much money involved why don't we widen and improve the rail through out the area as well, instead of just resurfacing.	**B2**
337	Station improvements in Maywood at 5th Avenue, Infrequent stop times at Metra Stations	**C5**
338	I live in Oak Park. Make the damn thing 4 lanes. There are people who will support you. Look at how well the I-294 project went. Lets start I-290 in 5 years. Then we can extend 53!!!	**A1**
339	Recommended 'fiscally constrained' solutions identified in the 'Regional Mobility' Section 5.6 - 'Cost and Financing' of the CMAP 2040 Draft Plan (pp. 180-194) indicates alternative transit related projects and upgrades to existing roads and highways. Roads and Highways for 2040: IL 53 North and IL 120 ; Elgin O'Hare Expressway ; I-190 access; Add lanes to I-80; Add lanes to I-88; Add lanes to North I-94; Add interchange at I-57 and I-294; Provide "Managed Lanes" along I-55; Provide "Managed Lanes" along I-90. Alternative Transit for 2040: CTA Red Line Extension; West Loop Transportation Center; CTA North Purple and Red Line Improvements; Metra Rock Island Improvements; Metra UP North Improvements; Metra UP Northwest Improvements and Extension; Metra UP West Improvements; I-290 Multimodal corridor provisions. Regarding the I-290 (Eisenhower) Corridor, the Draft Report states that the "the [I-290] project should require careful attention to minimize project impacts on adjacent communities and preserving options for transit in the Corridor." The report refers to IDOT's phase I engineering work for the modes to be chosen and goes on to state that "a multimodal approach is favored over simply adding lanes to the highway."	**B2**
340	Provide greater evaluation of fraontage roads, safety, on-off ramps and reduced width. Sustainability intiatives	**C2, C11**
341	CTA Forest Park terminal issues • Congested auto access and constrained capacity at the existing park-and-ride facility • Lack of direct express bus access from I-290 to the Forest Park bus terminal • Undersized terminal rail yard facility • Potential for relocation of terminal facilities to a new site between First Avenue and the Des Plaines River in Maywood (and TOD redevelopment of surrounding Maywood area and existing Forest Park terminal site)	**C5**
342	Regarding the purpose and need outline as it relates to the Village of Maywood:What about residential population areas not being served by transit (slide 9). Improve bus connection times between blue, green lines and Metra (slide 16).	**C5**
343	We [the park district] would like assurances that the investment that the community has made will not be laid waste by this project. Without the mass transit component, th econgestion will grow worse instead of better. Extend the Blue line, add some safe, well designed places to park a bicycle, figure out how to fund connecting bus lines, shove over and use some of the rail space for something other than storing flat cars. After these aspects are addressed realistically, then talk to me about taking a street and a line of homes.	**B2, C3, C5**
344	(1) Ultimately the Park District of Oak Park would like concrete evidence that there are absolutely no major impacts to our parks, buildings, or programs, whether it be physically, economicaly, or environmentally. (2) Extend the CTA's El Blue Line farther west to a destination spot, for example, Oak Brook Terrace or Downers Grove. (3)Arterial and non-motorized improvements should be proposed for the intersection at Harlem Avenue and Austin Boulevard. (4) Create a north-south HRT, CR, or LRT line, maybe along I-355, to connect to existing single and multimodal transportation systems that lead into interior suburbs and the City of Chicago.	**B2, B16, C3, C10**
345	Make all exits and entrances from right lanes	**C2**

ID #	Proposed Alternative Comment	Disposition
346	Can someone take a look at how the traffic on the eastdound Ike exit at Cicero extends all the way to Lavergne and sometimes Laramie Ave. This is a very big accident waiting to happen. It was a very scarry wait for the Cicero light at Lexington to change. Please take a look it happens everyday, especially around 10:am-6:pm When I'm sitting in the local lane waiting It only reminds ME of the kids that were killed when the truck rammed into the car or van they were in Pleas Help before it is too late!!!!!!!!!!!!!	**C2**
347	I attended Your open house on May 18th and YIKES! it was happenning all over again! You took my home for the Hillside Strangler Project and I moved to Elmhurst. I was studying your map of ALTERNATIVE #54 [CORRIDOR ADVISORY GROUP] which showed a rail line coming down Butterfield Road, RTE 56, to Oak Brook. Right past close to where I live! From the time the "Strangler" Project was announced until We received our "offer" From IDOT for our Home, The Real Estate value depreciated from $225,000 to $180,000. If you bring a rail line down Butterfield Road, you'll get Me again, depreciating the value of our property. Nothing like noisy trains to bring down property values. In Hillside, we lived next to the Railway and our home was much cheaper to purchase because of it. It seems like it is intended to bring "customers" to Oak Brook Shopping Center instead of alleviating traffic congestion. It reminds me of when some friends and family worked at NORTH RIVERSIDE SHOPPING MALL a number of years ago. They were always replacing stolen cars. The "JOKE" was --"I'm taking the EL and a bus to North Riverside Mall, but I'm Driving home!". Widen the Expressway from 25th to Austin or Central but don't Play West of Wolf Road.	**A1**
348	The blue line should be extended and light rail should be added. Expanding the IKE should be off the table.	**B2**
349	1. Include Desplaines ave in arterial study 2. Ironic & unfortunate that bicycle travel is not recommended at First Ave and DesPlaines Ave when Prairie path ends at First Ave and there is a pedestrian bridge over Desplaines River at Haybrook Court House 3. Rapid bus on Prairie path? No way!	**C3, C10**
350	1. Improve regional travel: Include Harrison from 1st to Austin & frontage raods (including garfield) along I-290 2. AGT would best serve as express rather station every 1/4 mile 3: Express bus should be express bus. 4. Express rail with Park-n-ride	**B4, B15, B16, C10**
351	Add bicycle lanes along 290 to connect downtown with the western suburbs. Please consider connecting the Prairie path east into the city.	**C3**
352	Take a look at the public trans that extended to the western suburbs. Please remember other plans like the "intercirc" which was going to link O'hare and Midway on the IL Harber belt.	**B2**
353	Fenwick High School advocates the inclusion of CTA Blue Line Rapid Transit Service from Forest Park to Hillside.	**B2**
354	Improve regional and local travel transit mode including people movers.	**B16**
355	Construct an elevated highway over the present expressway with limited access and egress. Extend Blue Line West along Prairie Path.	**B3, C8**
356	Please get rid of the left-lane on and off ramps at Harlem and Austin.	**C2**
357	The stoplight on 1st avenue going south that is near the expressway takes twice as long to turn green than the opposite side street light. Extend the blue line and add lanes.	**A1, B2, C2**
358	Extend Blue Line west, widen I-290 to 4 lanes to Cicero, redo Austin and harlem ramps to right side of expresway	**A1, B2, C2**
359	Bike /pedestrian-maintian (blue) improve(green)-These designations for blue should change to green or improve at Austin, Lombard, Sait and OP Ave. Most important at Austin and OP. Cap over the IKE at OP Ave.	**C3, C7**
360	Focus on better public transportation, green alternatives and cost effectiveness	**B2, C11**
361	The main push must be improving and extending the blue (and green) lines. Toll Eisenhower road during peak traffic okay. Bury the train under highway?	**A4, B2, B5, C9**
362	I strongly oppose adding a lane to the Eisenhower. Blue and green lines should be extended. Park and ride lots at terminal. The blue line could be moved underground. Eisenhower should be a toll road, increased toll during rush hour.	**A4, B2, B5, C9**
363	Raised monorail system from blue line down prairie path to Dupage.	**B16**
364	The roads need to be widened and public transit needs to be extended.	**A1, B2**
365	Extending public transit westward should be the first priority. I would ride my bicycle more if safety was assured. More "improvements" or widening Roosevelt Rd seems like a bad idea.	**B2**
366	I would love to be able to take public transportation that runs 24/7 at least to Oak Brook. I also agree in principle with changing the Harlem & Austin Ave ramps to right-hand ramps.	**B2, C2**
367	Move all Eexit/entry lanes to right side, add lanes to avoid congestion, no bus lanes, no bike lanes next to car lanes	**C2**
368	I really like the people mover concept.	**B16**
369	The project should not seek to increase traffic on local arterials such as Ridgeland Avenue. New interchanges at these types of roadways that cross I-290 should not be part of the project.	**C10**
370	Maintain praire path with new roadway improvements. Provide buffers (physical) & space between bicylle and roadway. Love to see the "round abouts " to help with arterial traffic congestion	**C2, C3**
371	The following conditions need to be included at Oak Park Ave, Home Ave, and East Ave over I-290: "Improved Conditions for Pedestrians"/"Suggested Interchange Improvements"/ "Suggested pedestrian and bicycle improvements."	**C3**
372	I agree we have to ease the congestion on 290, not by adding more lanes or changing ramps, but by extending the current rail lines further west.	**B2**
373	Extend the blue line.	**B2**

ID #	Proposed Alternative Comment	Disposition
374	Consider bicycle and pedestrian crossings/paths for your design. Connections to the Illinois Prairie path should also be considered.	C3
375	Extend the blue line out to Oak Brook along existing infrastructure.	B2
376	Extend blue line. Extend Green Line. Add NS Metra Line N IL 59. No commerical trucks on I-290.	B2, B5, B10
377	Pace, CTA, RTA how can their contribution to the over-all logistical equation be changed go as to decrease individual relinace on single-vehicle traffic.	C5
378	Focus is pointed more toward increasing number of vehicules on road, rather than increasing efficiency & reliability of mass transit. Why? Increasing safety: if there were fewer vehicules on road, the highway would be safer. Increasing mass transit would reduce vehicules on road. Why is this not being emphasized more?	B2
379	The initial alternatives do not include improvements for pedestrian and bicycle crossings at Oak Park Avenue or at the Home Avenue pedestrian bridge. Wider sidewalks, curb cuts and concrete repairs are sorely needed for safety and ease of use of these heavily traveled crossings.	C3
380	1) Suggested one way frontage road (arterial improvement). Am concerned this would create unitended conseguenses of higher traffic in residential side roads. Need the proposed modeling and integration with other soultions to understand what this could mena. 2)Construct additional general purpose lanes. First priority should be to take space from rail not frontage road. Widening expressway beyond existing frontage is couterproductive to goals. Not for optimizing existing footprint is fine.	A1, C10
381	Trains/buses are the way to go. Tunnel from the Hillside Strangler to west of the I-290-90/94 interchange. Put trains and express lanes in tunnel.	B2, C9
382	Include area for wildlife crossings at Des Planines River and Addison Creek	C11
383	Widening the Ike will not relieve congestion. Rapid transit is more environmentally friendy, creates jobs and improves access to jobs	B2
384	Don't close Austin entrance. Just reroute Harlem or Austin Ramps to sides. Fix rapid transit entrances by moving entrances off main street. Last but not least to fix congestion on Eisenhower destrot it completely	C2, C5
385	AGT-Follow 290 route to 88 to Oakbrook/Yorktown. Use the mall lots as park and ride. Do not extend blue line through river forest on old rail tracks. Rather extend blue line as above with AGT to Mannheim.	B16, C11
386	Make more lanes for the ramp for 294 south. Different on and off ramps in the most congested areas. Make semi-truck only lanes.	A1, C2
387	Extending the 4th lane all the way to Mannheim would be a tremendous help. Also, north-south pedestrian/bike routes need to be added at DesPlaines and Harlem.	A1, C3
388	Just restripe, contrinue 4 thru lanes between Central and Mannheim.	A1, C11
389	Expand transit to points west and multi-use trails	B2, C3
390	Have two lanes meet two lanes on the I-290/I-88 merge to become four lanes.	A1
391	Prefer expanding public transit options over "highway only" options. However improvements to entrance/exit ramps needed for improved safety.	B2, C2
392	We support adding the blue line extension, possibly buying and putting metra lines on the CSX railway and adding other forms of transportation (monorail, bus lines).	B2, C5
393	Consider expanding CTA rail corridor west, more public transport options.	B2
394	The best option for reducing congestion seems to be extending the CTA Blue Line (and improving its service). The blue line used to run to Westchester and should once again.	B2
395	Use the Harlem blue line entrance frequently. Not only is it not ADA compliant but it is also very dangerous for all pedestrians. Please use this reconstruction as an opportunity to improve conditions for pedestrians accessing CTA median stations.	C3, C5
396	Yes to pedestrian improvements suggested. Yes to improvements for bikes. Yes to BRT service. No to widening 290.	B7, C3
397	Alternate public transportation items need to to be fully considered. The RTA Cook-DuPage corriodr study outlines a number of these transit options that would reduce inbound/outbound congestion along I-290	A1, B9, C5
398	I favor the following solutions: 1. Add a 4th lane to the Eisenhower between Austin and 25th avenue. Negotiatewith the CN railroad to purchase their right of way through Oak Park so the road can be widened in the existing trench. 2. Improve Metra and CTA service especially the reverse commute options on Metra for commuters who work in DuPage County.	A1, B9, C5
399	Please do not add any more capacity for cars on the Ike…We must have better interconected public transit with easy transfer across systems.	C5
400	Reversible HOV lanes could satisfy most of the peak hour problems of the IKE without requiring a widening of the ditch. In the alternative, I would prefer to see the Blue Line extended to at least 1st ave. A partial cap should be built whether or not lanes are added [through Oak park]. More and better public transportation coupled with policies which discourage auto travel would be the best course of action.	A2, B2, C7, C11
401	Adding a fourth lane will align the highway and eliminate westbound strangle and improve the eastbound trip. I am against tolls. And transit. No more. The area has tons of transit holding up the surface roads. Also an interchange at Norht avenue and 290 to 294 would reduce that strangle on 290.	A1, C2
402	Connect Cermak to 294N to I-88N ramp to divert I-290 traffic that could use Cermak and avoid Oakbrook congestion when going Cermak to I-88 West.	C11
403	I love blue line extension but need express lane to make it successful. (1) Travelers loop to Oakbrook need trip to be short, easy (2) Every day commuters who work in loop/Oakbrook need express can't stop at all stops or will take over.	B2, B4

ID #	Proposed Alternative Comment	Disposition
404	Proposed Prairie Path, Realignment per CMAQ, Butterfield Road Reconstruction Project, Widening: Reconstruction. Prairie path to travel north via Mannheim to Washington, Mannheim then cross, travel west to exist offroad path at Forest.	**B10**
405	Provide additional space for bus loading/unloading. Get rid of center on/off ramps. Provide longer on ramps (thru traffic is hindered by turning vehicles). Build larger turn lanes for long semi-trucks (turn radius)	**C2, C5**
406	(1) Extend blue line to Oak Brook. (2) Ban commerical trucks between Mannheim and Cicero-better to loop. (3) Create tollway authority under state control. (4) Metra line following approx IL RTE 59.	**A4, B2, B10, C11**
407	Eliminate either Central Ave or Austin Blvd interchange. (1) Eliminate Austin Blvd interchange, Have CTA put Central Ave stop on Blue Line back in service and improve pedestrian and bike access at Austin Blvd. (2) Eliminate Central Ave interchange-improve pedestrian, bike and CTA bus access at Austin Blvd.	**B2, C2, C3**
408	Maintain 1 1/2 miles between interchanges. Ie eliminate interchanges at 9th ave, 17th ave, DesPlaines, Central Ave. Improve ped, bike, and bus acess at remaining interchanges. Improve ped, bike, and bus access at DesPlaines, Circle, OakPark, East, Lombard, Central Ave.	**C2, C3**
409	Need better links between Metra and Pace. Especially for reverse commuters.	**C5**
410	Ped crossing at Harlem and I-290 is dangerous due to ramp configuration. Consider express CTA service from DesPlaines station to UIC Halsted, Med Center, or Jackson. Consider BRT along Harlem to Midway and North to O'Hare. Consider widening bridge at Circle Ave.	**B7, B15, C2**
411	BRT along Roosevelt and Mannheim to North interchanges at North, Melrose park station, Prairie Path, Roosevelt. No to "expressway improvements" (ie don't build more lanes). Express Blue Line (take auto lane on each side for 2nd rail line to allow express to pass) expand park+ride to encourage people to use these trains.	**B2, B4, B7, C11**
412	Transit needs are overlooked. We need more options and alternatives to driving.	**B2, C3, C5**
413	(1) Extend the blue line west to at least Oakbrook and eventually to the starline. (2) Improve the current bike trail and extend it into at least Oak park-connect it to the blue line.	**B2, C3**
414	I am writing to provide comments on the DRAFT PURPOSE AND NEED document for the I-290 proposed activities. The plan is geared toward highway expansion which will not alleviate highway congestion in the long run. If more lanes are constructed, more cars and trucks will find their way to I290 and will again become as congested as before the lane additions. A more holistic solutions needs to be found. If transportation issues are to be solved along the I290 corridor, the CTA Blue Line needs to be expanded/upgraded. (Special busing routes should not be created to overlap with the Blue Line coverage, this is spending extra funds on providing a repetitive public service.) More freight traffic can be directed along the rail lines south of the CTA Blue Line to alleviate truck traffic. The left side exit and entrance ramps are said to be unsafe, however in 9 years of living in Oak Park and my 38 years of living in the Chicagoland area, I have never seen an accident along this area. Traffic may slow down from the 70 mph speed of the vehicles, which may cause traffic to slow down to 55 mph - the legal speed limit on the road. If unsafe conditions are being caused, it is not due to the left hand ramps, but to drivers not obeying the speed limit. With the price of gas ever increasing, I am not sure why the state is putting more resources into road expansion. People are reducing their driving and taking public transport to save money. Any state funds need to be reallocated to supporting other forms of transportation. Also, the increase in traffic, will only decrease the living standards and health of the families living along this corridor and beyond.	**B2, C4, C5**
415	The most viable solution to transportation issues in the corridor is the expansion of the CTA Blue Line further west. Such expansion will accomplish the d ual goal 1) moving people through the corridor, and 2) reducing vehicles on I-290. By reducing the number of single occupancy cars, there'll be more capa city for truck traffic; which seems to be an underlying and unstated goal of this study.	**B2**
416	A "managed" lane, using only the existing structure would lead to even worse traffic jams. The Blue Line should be extended farther west, to reflect grow th in those areas. Long term planning should consider a monorail, which would free up more space beneath and be quieter. Unlike most Oak Park reside nts, I do think that it should not lose a lane at Oak Park. Not only is the backup annoying it puts a tremendous amount of fumes into the air. One way to expand the highway without encroaching farther on private land would be to have the blue line be a subway all the way and use its current space for cars . Perhaps more practically, the subway could begin at Austin Blvd, and then a lane could be added without taking any more Oak Park land.	**A1, B2, C9**
417	As a student at University of Illinois at Chicago, I would like to see the Morgan Street exit more aesthetically appealing. I am interested in involving stude nts in a project to build a garden that can enhance its appearance. Who controls the property on the east side of the highway there?	**C2**
418	Extend study area east to Wells or Michigan, Extend Blue line to Hillside and beyond	**B2**
419	As an Oak Park resident, I strongly urge for improvements in pedestrian and bicycle transportation in the Ike corridor, specifically at all crossings (Oak Par k and Ridgeland Ave. especially, repair/improvement of the Home Ave. pedestrian bridge, and more pedestrian bridges if possible. I also strongly oppos e expanding the Ike footprint in Oak Park. There should be no added traffic lane studies have shown it will not ease congestion. We need rail and alternate transportation, not more auto congestion. Further, the existing off ramps sho uld not intrude further on Oak Park. The left exits are unique in the minimal intrusion on our limited space, and giving up space for "modern" off ramps i s moving in exactly the wrong direction.	**C2, C3**
420	better mass transit and bicycle-friendly and pedestrian-friendly features along 290 Beautification of the corridor on all exits entering Oak Park - Harlem, Austin bike friendly curbs and streets along Oak Park Ave. , Home Street and 290 bridge improvements trash removal along highway and exits!	**C3, C5**
421	HRT to oakbrook, AGT to oakbrook, ped and bike improvements	**B2, B16, C3**
422	Extend Blue Line, Improve intersections along I-290	**B2, C2**
423	I strongly support: (1) HRT to Oak Brook or (2) AGT to Oak Brook and (3) non motorized pedestrian and bicycle improvements. I strongly oppose: (1) HOV lanes (2) Expressway expansion/improvements (3) arterial improvements	**B2, B16, C3**

ID #	Proposed Alternative Comment	Disposition
424	You have to look prior to Mannheim. The 294 / 290 interchange needs to be addressed. Traffic coming from 290 east onto 294 south backs up 290 to Yor k road. There is plenty of room here to use the fly over interchange. This is a major interchange and the current configuration squeezes 290 east inbound traffic to 1 lane due to 294 south bound traffic. The same occurs on west bound 290 traffic on a smaller scale when 294 merges onto 290 thru York road. f: congestion after Manheim. I do not understand why there is only 3 lanes from route 83 to Austin. There needs to be a Min of 4. The population of the metro area has exceeded the capacity of the current system. Austin to Circle should be 5 lanes. Traffic at the 53 90 interchange are at times 6 lanes and that over 40 miles from the City. Parking Garages. The court house and CTA would both benefit from parking garages to free up some land move the trai ns in to the parking lot and cars above the trains. g. In the places where land is tight why not use suspension bridges, expensive but effective. I also thin k concrete walls need to be built like they did on the Dan Ryan, even if your not going to expand lanes to the wall, use that space for shoulders to get bro ken down cars out of the way. h. Raised reversible express lanes. I know land is a premium. Also do not do 2 lanes like you did on the Kennedy It only tak es one problem in the express lane to make the solution the problem.	**A1, C2, C11**
425	We live on the south end of Oak Park, and my primary concern is making the El Stops at Oak Park Ave and Harlem Ave more pleasant and easier to use. The overpasses at these two streets are too narrow for pedestrians and bikes. The El stops are unpleasant (compared to some of the new stations in the city). The pedestrian bridges e.g. Home Avenue, over 290 are in horrible shape - dangerous to walk over and worse for biking due to uneven broken con crete.	**C3, C4, C5**
426	Expand the Blue Line to add commuters on the rails not the highway! Expanding the Ike is not solving the problem! Look at ways to make El & Metra acc ess easier for those in the burbs.	**B2, C5**
427	What?? Expand the IKE-our village was already cut in half when you built it and you tore up our trees bringing water to the western suburbs. How about Public transportation..I take the blue line every day. Extend it, make it cleaner and safer and I think you may have a solution that will save lots in oil consumption, congestion and our tax dollars.	**B2, C4, C5**
428	Encourage public transportation!! Another waste of our tax dollars. We need alternatives and when people have an option that saves them money they will use it. If you have to have consultants-use some that are from the area!! Not Denver residents that don't have a solid public transport system....how about some commone sense here-quit wasting our taxes on consultants!!	**B2**
429	We need to reform and expand the CTA and Metra options in order to be a viable city of the future.	**B2, B9**
430	I am shocked beyond belief that in this day of $4.50 + /gallon gas and an increased awareness of the health and political costs of our reliance on foreign oil that an major highway expansion is even being considered. Experts in the field (talk to someone at McKinsey & Co. and scientific experts) readily agree that the U.S. is rapidly approaching or has already passed peak oil production. The coming years near to provide replacemens for a car driven culture, not a pathetic attempt by state agencies to get more money by expanding our roads. Most middle class people cannot afford a $5/gallon commute from the far western suburbs on top of expensive city parking. We need to reform and expand the CTA and Metra options in order to be a viable city of the future.	**C5**
431	Please reconsider widening the IKE in the Oak Park area. Please DO consider more public transportation	**B2**
432	I am in favor of expanding blue line service to the far western suburbs. Not only would expanded blue line service relieve traffic congestion on the Eisenhower, but it would also offer a less expensive way for people to commute to downtown Chicago from the western suburbs. Widening the Eisenhower, by contrast, will encourage more people to drive to work, thereby increasing pollution. Widening the Eisenhower will also have a negative impact on communities like Oak Park. Housing values will decline as noise and pollution increase from an expanded Eisenhower. I am opposed to expanding the Eisenhower expressway. Widening the Eisenhower is not a cost-effective or environmentally sound solution to reduce traffic congestion.	**B2**
433	As a commuting stakeholder, I have the following comment and suggestions: There's more than enough room currenty on the Eisenhower to transport more than double the people that are currently travelling on the road. The key is to get rid of all of the empty seat hauling that we're doing. Sadly, 90% of all commuter trips have only one person in the car - the driver. 98% of all commutes have only one or two people in each car. The solution is to manufacture and drive narrow cars - cars with all of the passenger seats behind the driver. That way there can be more than double the existing number of lanes on the roads without widening the highways. I couldn't disagree more with widening the road as a solution. There's no reason to believe ultra-narrow car technology won't take over the highways as fast as computers, cell phones, and smart phones have in a 20 year span. To start, then, legalize lane splitting and create "Congestion Passing Lanes" in the middle of the highway where only narrow cars and motorcycles are allowed to lane split. Public service announcements from newspaper, radio, and tv news would communicate the need for careful lane changing in the middle of the highway during congested periods. As people would see the narrow cars and motorcycles passing the congested traffic, more and more people would transfer to this type of vehicle. For more information, see www.deletetheseats.org and www.commutercars.com. Delete the seats.	**C11**

ID #	Proposed Alternative Comment	Disposition
434	This is a time of great opportunity to place Chicago at the forefront of modern transit. Expanding the Ike is not the solution. With gas prices at an all time high, and with such unrest in the Middle East, this is not a time to increase our reliance on oil. This is an opportunity to improve public transit via the CTA and Metra. Now is the time to utilize financial resources towards a state-of-the-art high-speed rail system. I strongly believe that expanding the Ike is NOT the answer. It would be a band-aid not a solution. We must expand our thinking and imagination and use this opportunity to implement alternative commuter resources that do not rely on fuel-reliant vehicles. Chicago suburban-area residents need alternative commuter transportation. The cost of living continues to climb while wages remain stagnant. Forcing commuters to rely on their vehicle is not the answer. Chicago parking rates are ridiculously high. These rates limit my family's participation at Chicago attractions and events. We deserve an alternative mode of high-quality transportation. If resources are or become available, do not force Chicago-area residents to rely more on their vehicles. Give us the opportunity to use our tax dollars towards improved and reliable public transit. Specific factors that could improve the commuter experience are 1) a more accessible and 2) sanitary CTA. The current state of the CTA limits our participation in Chicago events, attractions, shopping, etc. As touched on, we cannot afford parking in downtown Chicago. In addition, we are limiting our car use due to the high price of gas. Therefore we usually take the blue line into the city. However, we have a young child and always travel with a stroller. The limited number of CTA stops with elevator access is unacceptable. Not only that, but the elevators that do exist smell so horrible of urine that it keeps us from visiting the city. Improving CTA and alternative rail systems is the answer. With these improvements, our family would take greater advantage of all that Chicago offers, aka, we would spend more money in Chicago. Expanding the Ike would not be the answer. Chicago can do better. We as arearesidents and tax payers deserve better.	**B2, C4**
435	I commute on the Eisenhower every day. Public transportation isn't an option for me due to the nature of my work. While improving the blue line should be part of this improvement, many people like myself simply can't abandon their vehicle in favor of public transportation. We are at the mercy of a poorly designed road. There is room to improve it and make it flow. Restricting access from other roads would help. Why do we need all the avenues pouring in? Cut off a few and have the merging roads reduced. I like the separated road Eastbound near the old Hillside Strangler. You should extend that to 171 so that all merging/exiting traffic doesn't mingle with the three lanes of the Ike until after 171. The Central access going Westbound is too close to Austin, which is too close to Harlem. Finding a way to route Central onto Austin and eliminating that access would help a ton. Right now people exit at Austin, then jump across and enter on the other side passing 40 cars, but snarling traffic at the merge on the other side. Changing the lights to prevent this will help.	**C2, C6**
436	Please consider the inclusion of a parallel lane for cycling commuters, similar to the lake front path of LSD.	**C3**
437	With the rising cost to operate an auto and the environmental effect of a higher number of cars traveling through the Oak Park corridor it seems that dollars would be better spent to expand the rapid transit system which could use the revenue. Especially with the program being put in place that would take free travel away from senior citizens. There is definately something in this program that clearly shows a hugh profit for individuals that do not deserve it. The time is coming when we will find that if we do not start putting constructive programs in place not only will Oak Park loose its standing as a community that cares, but our state revenue will collapse and the likelihood of an overpriced expansion being completed properly almost impossible.	**B2**
438	Please do not expand the Ike. Adding HOV lanes will not significantly reduce congestion. Only a multi-modal solution of expanding blue line, metra alternatives,and possibly light rail will reduce congestion.	**B2, B9, B17**
439	I am a resident of Oak Park and live near the highway. I am against the expansion of the Ike since it will have a detrimental impact to a historic community and will only perpetuate our reliance on automobiles. Instead of more lanes, the train service should be expanded and improved. For example, lengthening the Blue Line will draw additional commuters from communities not well serviced currently, e.g. Maywood, Westchester, Hillside. A high speed rail system should also be considered. Finally, there are freight tracks that are RARELY used that is taking precious real estate. Perhaps these can be used to create express Blue Line tracks.	**B2, B13**
440	Make it a double decker expressway	**C8**
441	Why can't they double-decker the highway.	**C8**
442	If new lanes are going to HOV lanes, don't bother - waste of money, unless two lanes are added: 1-HOV, 1-unrestricted. "Congestion pricing"? Why penalize commuters for something that's not their fault? If the road was built right in the first place it wouldn't be congested.	**A1**
443	Could an elevated in/out express lane be a possibility? Where possible build it over the Metra tracks until Metra goes below ground and at that point bring it over the east/west lanes that currently exist. Have 5 mile stretches without on/off ramps to handle the suburban traffic and not the intra city traffic	**C8**
444	As a resident of Oak Park for most of the past 25 years, including three in a house facing I-290 and nine in a house within 100 yards of the expressway, I am absolutely against further widening of the expressway through Oak park. The level of noise, soot and air pollution is already a detriment to the quality of life in this area, further widening this expressway will exacerbate these issues without eliminating tarffic congestion or even mitigating it in any meaningful way. Congestion will remain and our community will pay a price for little or no reward/benefit to the greater metro area. What is needed, as soon as poossible, is a sound wall to contain and mitigate the noise caused by the expressway, the blue line, and the rail lines. Further expansion of the blue line makes absolute sense and should be the first priority when reconsidering the Eisenhower.	**B2**
445	Its so easy.Double deck it.You would have twice as many lanes right away.We have the technology to prevent collapse.only have to plow snow on the top lanes.Dont have to buy more property.	**C8**
446	I agree with nearly all of the suggested steps. Definitely: e. Widen the road to three lanes west of Austin to eliminate the bottleneck. f. Extend the CTA Blue Line to Yorktown shopping center, but you would need express trains to speed up the trip. (The CTA used to have 'A'trains and 'B' trains that each made every other stop, except for a few stops where you could change trains. That made sense.) g. Expand parking at the CTA stations. I would use the Blue Line a lot more, but the parking at Forest Park is a nightmare. You should be able to use a credit card to pay for parking.	**A1, B2, B4, C11**
447	With the high cost of adding lanes, which would not necessarily reduce congestion, I think the best solution is to construct an elevated, four lane expressway with limited entrances and exits. Many of the vehicles entering at 294 are headed to the loop. Frames that span the tracks or hammer head piers could support the structure with high level bridges at the existing overpasses	**C8**

ID #	Proposed Alternative Comment	Disposition
448	We believe that it is not possible to build our way out of congestion on I-290. The "Hillside Strangler" project has demonstrated that. There is too much congestion – 17 hours each day – to make a dent by adding another general purpose car lane, as has been suggested. Moreover, adding a lane on I-290 would eventually attract more cars, resulting in comparable levels of congestion but with even more traffic. The best strategy for reducing congestion, improving mobility and safety, and creating better access to jobs in the I-290 corridor is to make it easier for travelers to use transit, biking, and walking for work commutes and other trips. We need a combination of new Bus Rapid Transit service; improved service on existing rail, (CTA and Metra) and bus (CTA and PACE) lines; better, faster bus connections to CTA and Metra rail; and better, safer bike and pedestrian access to transit and jobs. IDOT should focus on these alternatives as the study continues.	**B2, B7, B9, C3, C5**
449	What the Ike corridor needs is not more cars, but more trains	**B2**
450	I would like to suggest that the advisory group consider the addition of dedicated bike lanes in any improved design of the Eisenhower. Dedicated bike lanes would dramatically lower bike commute times, which would in turn increase the number of bike commuters from nearby communities like oak park, forest park and river forest, resulting in lower vehicle traffic volumes. Compared to a multi-modal route, such as walk, train, walk, or bike, train, walk, a unimodal route is typically much preferable. Separate bike lanes on the highway would make biking a competitive option to public transit as well as driving, from communities within 10 miles radius.	**C3**
451	What is needed is 4 LANES in the proposed stretch of road. Save up funds for this and do it right. Maybe do east bound 4th lane first, then west bound later after more money becomes available. (maybe Federal jobs program money) Keep buses off! I see problems with that. Also, no tolls. This was supposed to be a free road. What happened to all the fuel taxes we paid? Keep the Tollway commision as far away as possible from Ike. Why single out Ike for tolls? If Ike is tolled, then why not all exoressways? If nothing else, continue eastbound 4th lane east of 25th Ave. (between railroad bridge abutments, I think there is room.) Also, moving Harlem & Austin ramps to right side of expressway makes sense, but how to do this with RR tracks on the south? If possible, this would almost make enough room for another lane(s) thru Oak Park. If Oak Park doesn't cooperate again, I have a couple of suggestions: e) close all ramps to & from Oak Park. Evidently, they do not need Ike. f) keep ramps open but toll those ramps only Seriously, I've spent a ton a of time in the "suburban squeeze" over decades of commuting on the Ike. Extending the light rail line further west is also a good idea.	**A1, B2, C2, C11**
452	These are my thoughts: e. As much consideration should be given to improving public transportation including the CTA Blue Line as is given to expanding the lanes on the Eisenhower. f. Reversible lanes are a waste of time on the Eisenhower. g. I believe express bus lanes will have a minimal impact on reducing congestion. Going north on the CTA – four train lines occupy the same platform in the most heavily populated area, and three lines thereafter. Although this accommodates mostly rush hour traffic it allows a great deal of flexibility for commuters. If another line could that catered to commuters and expressed to forest park from downtown or maybe Illinois Medical , turned around at Clinton or LaSalle and then ride back out to Hillside or Rolling Meadows. i. I understand there is talk of expanding the CTA line. If it is expanded it should be expanded at a minimum to Hillside and most likely to Rolling Meadows. j. If the goal is to allow commuter to travel to and from work – some attention should be paid to 24 hour transit and bus service. k. Bicycles – A bike only path should extend from downtown out to Forest Park with exits only at certain main streets. The path should be lit have reflectors on the ground and along the sides, and be patrolled by officers on bikes, 3-wheel or 4-wheel carts, or Segways and be closed to other motorized or foot traffic. l. Trucks should be barred from using the Eisenhower during certain time periods. m. Flexible toll rates will force drivers to other routes but will not ease overall congestion. c. Congestion may be eased if a second "elevated" 4 to 6 lane Eisenhower were built for cars only.	**B2, C3, C5, C8**
453	I think extending the Blue Line to Oak Brook would do a lot to cut down on vehicular traffic	**B2**
454	Sure we can use more public transp., but the road needs to be four lanes all the way to 88/294.	**A1**
455	Please consider IMPROVEMENTS IN TRAIN SERVICE including expansion of the Blue Line westward to Oak Brook in order to decrease vehicle traffic that generates noise and pollution in residential areas.	**B2**
456	I have lived near the Eisenhower most of my life. I feel strongly that we need to extend the rail line down the middle of the Eisenhower that would go all out to Oakbrook and beyond. The drive down the IKE is now pushing people away from living here....I hear it all the time.	**B2**
457	I do not think the Eisenhower expressway should be widened. What the area needs is better public tansportation and transportation links instead.	**C5**
458	I would like to see more federal and state monies going to support public transportation and encouraging bike use instead of building more roads or wider roads. We have enough car and oil use as it is.	**B2, C3**
459	It is foolhardy to add highway lanes in the 21st century. We cannot afford financially or ecologically to reinforce automobile travile in urban areas. Extend and improve blue line. I would love to be able to take it to Oakbrook. We go downtown all the time to cultural events, to eat, to shop, no arguments about what lane to be in. no parking fees or hassle. My recent observation of ike drivers while riding the blue line was the high precentage of one occupent cars. HOV lanes arne't going to be very popular and you will have delayed (expensively) the inevetible need for transportation.	**B2**
460	Establish Ramp at Racine, Morgan ramp is inadequate	**C2**
461	My idea would be to make the expressway into a variable speed expressway (VSE).	**A2, A3**
462	Request a high-performance bus alternative as managed lane or dedicated lane as replacement to blue line	**A2, A3, B7**
463	I was unable to attend the last meeting, but my idea is to simply add 2 lanes, but make them toll lanes. Charging a toll would deter much of the traffic from entering what would be express lanes. These would be built on both sides of the expressway, and eventually be paid off by the tolls. The tolls would then help pay for the cost of repairs.	**A3**
464	ITS at access points to I-290.	**C6**
465	Smart Corridors [TSM]	**C6**

ID #	Proposed Alternative Comment	Disposition
466	Station/roadway improvements - ITS/TSP; Roosevelt Rd - bus turnouts & limit peak [-period] parking; park & ride at Wolf; guided bus on [Illinois Prairie] Path - TSP at intersections.	**C5, C11**
467	Shift CTA ROW to CSX for improved stations, increased platform width, and connections to neighborhood. Add park & rides at intermediate stations. Begin shift to CSX ROW at approximately Cicero Ave and extend to Des Plaines Ave.	**C5, C11**
468	Express bus from Metra train station in Maywood along 5th Ave to Loyola. Stops at Washington Blvd, Madison St, and Roosevelt Rd.	**B15**
469	Better connection from Metra train stop to Cook County Court House (not timed right currently).	**C5**
470	Bus routes - Ridgeland Ave and Central Ave route to open Blue Line station at Austin Blvd; Laramie bus to Cicero Ave.	**C5**
471	Redevelop CTA Blue Line Harlem station.	**C4**
472	Redevelop CTA Blue Line Oak Park station.	**C4**
473	Redevelop CTA Blue Line Austin station.	**C4**
474	Increase park & ride capacity at Forest Park and improve connections to roadways for bus and auto, improve connection to Prairie Path, rebuild CTA yard and shop at Des Plaines Ave, widen bridges at CTA connections and bus routes crossing I-290 for improved pedestrian access, bike facilities, visibility, and improve drainage in I-290 corridor including CTA facilities.	**C3, C5, C11**
475	Provide improved connectivity for regional bikeways. 1) Extend Illinois Prairie Path east, connecting with off street bikeway in Columbus Park, further connecting to the City of Chicago "streets for cycling" system. 2) Improve prairie path crossings of SRA's preferably with grade separations. 3) Provide crossing of Des Plaines River Trail (proposed) across I-290. 4) Provide linkages from Prairie Path and Salt Creek Greenway to new and developing commercial uses in Hillside (see Hillside ITEP submittal proposed in 2010). 5) Provide undercrossing of I-290 in Northlake.	**C3**
476	Formal request to analyze the potential for a major new off-road trail connecting to the Illinois Prairie Path and other local and regional bikeways within the study corridor. Create an extension of this trail [assumed Illinois Prairie Path] to connect western Cook County communities to the City of Chicago ... IDOT's current study could be the first step in creating a new Eisenhower Regional Trail.	**C3**
477	Please improve existing pedestrian and non-motorized sidewalk infrastructure (i.e. 1st Ave on east side of street north of I-290). Access across I-290 ditch is poor along I-290 corridor. Limited bicycle parking along I-290.	**C3**
478	1) Improve interchange area non-motorized crossings and safety focus on Austin Blvd, Harlem Ave, DesPlaines Ave, 1st Ave, 17th Ave, 25th Ave, Mannheim Rd (see regional bikeway sheet). 2) Provide wide bike-pedestrian crossing of expressway; where widening is not feasible separate walkways from traffic with a safety barrier. Provide crossings every 1/4 mile where expressway separates communities to eliminate barriers to walking. 3) Provide bike lanes across expressway on non-state roads. 4) Minimize bike/pedestrian crossing distances over heavy-traffic facility. 5) Provide transit access improvements.	**C3**
479	Improve arterial and non-motorized opportunities for intersections at Harlem Ave & Austin Blvd. Maintain bridge access at Lombard Ave, East Ave, and pedestrian bridge at Home Ave.	**C3**
480	Pedestrian/bike improvements at expressway Interchange.	**C2, C3**
481	Use single point [urban] Interchange to minimize pedestrian/vehicle interaction and enhance safety and neighborhood quality	**C2**
482	Change exits to center lane exits (rather than right lane exits) to provide consistency and improve quality of neighborhood experience, and improve pedestrian safety. Interchanges include Mannheim Rd, 25th Ave, 1st Ave, Central Ave, Laramie Ave and Cicero Ave.	**C2**
483	Interchange traffic circles at 4 locations - 1st Ave, Harlem Ave, Austin Blvd, and Cicero Ave.	**C2**
484	Major interchange improvements along I-290 (1st Ave, Austin Blvd, ramp access on & off I-290).	**C2**
485	Same interchanges but modernize them and no left-lane ramps.	**C2**
486	Eliminate interchange to reduce expressway vehicle conflicts and manage expressway VMT. Provide access management on approaches to remaining Interchange through intergovernmental agreements. Provide better local street connectivity (assume existing bridges to remain). Improved local street connectivity will reduce interchange congestion. Complete interchange or expand interchange capacity.	**C2**
487	EZ access on/off ramps from I-290 to Forest Park station.	**C2**
488	Frequent (15 min headway) system of express bus routes on new or converted HOT, HOV, or bus lanes. Routes would originate on the west at the intermodal terminal in Forest Park or Hillside. Bus routes include destinations along 1) Western Ave N & S; 2) Michigan Ave in Streeterville; 3) along Cicero Ave north and Cicero Ave to Midway Airport; 4) to Medical Center (at Ashland Ave); 5) Hyde Park and University of Chicago. Buses operate express along I-290 and limited stop along arterial streets. Intermodal terminal would include park & ride lot.	**B15**
489	Improve park & ride option at Forest Park station based on analysis of need, assuming Blue Line extension.	**C11**
490	Larger parking lot at DesPlaines Ave.	**C11**
491	IDOT Rapid Deployment Emergency Crash Removal Program - Know there is some program presently, but development of emergency lanes and emergency signal/info devices on highway to allow faster access to crash site for removal. Area shown within project limits - Mannheim Rd to Cicero Ave.	**C11**
492	Re-evaluate multiple bridge crossings at Des Plaines and create two way access to and from Van Buren for better access to station.	**C10**
493	Arterial improvements on Roosevelt Rd to improve bus flow and amenities.	**C10**

ID #	Proposed Alternative Comment	Disposition
494	UP-W line-within-a-line from Cicero Ave to Elmhurst for reverse commute. Stops at Cicero Ave, Harlem Ave, 5th Ave, Broadway, Mannheim Rd, I-294 and York Rd.	**B9**
495	Melrose Park and Bellwood have suggested through RTA community planning (former RTAP) process to combine stations with a new station near 25th Ave.	**B9**
496	Upgrade existing Metra service to make it an attractive commute option along the UP[-W] line. Increase frequency of trains, demo fares (fare integration), improved station facilities.	**B9**
497	Capacity improvements on Metra BNSF and UP-W. Five additional peak limited stop trains.	**B9**
498	Upgrade service on Metra's MD-W line.	**B9**
499	3 train service on Metra UP-W line; upgrade signal systems for trains.	**B9**
500	Metra MD-W Service Expansion	**B9**
501	Metra UP-W Service Expansion	**B9**
502	Metra BNSF Service Expansion	**B9**
503	Harlem Avenue	**C10**
504	BRT Roosevelt	**B8**
505	BRT along Cermak Rd from 54th St to I-355.	**B8**
506	BRT in exclusive lane on Roosevelt Rd; integration with J-line on west end.	**B7, B8**
507	BRT line in the existing "ditch" along I-290 from park & ride facility at Hillside to downtown Chicago. Should include express capabilities and have key stops at I-294/I-88/I-290, 1st Ave, Harlem Ave, Austin Blvd, Cicero Ave and Western Ave.	**B7**
508	BRT, Loop to I-355 via Blue Line ROW, I-290 and I-88	**B7**
509	Mid-City BRT	**B7**
510	I-290/I-88 BRT [1st Ave to Highland Ave]	**B7**
511	1st Ave ART	**C10**
512	East and west power line corridor [assume to be adjacent to Illinois Prairie Path]. Busway.	**B8**
513	I-290 managed lane (price and/or occupancy) from Cicero Ave to I-355 with a BRT lane from Des Plaines Ave to I-355. BRT stops at I-355, Main St, Meyers Rd, Summit Ave, Kingery Hwy [IL 83], York Rd, Wolf Rd, Mannheim Rd, 25th Ave, 1st Ave, and Des Plaines Ave.	**A2, A3, B7**
514	DuPage "J" Line	**B7**
515	CTA Green Line extension from Forest Park / Oak Park to Maywood. Stations located at 5th Ave and 19th Ave. (60% of employed Maywood residents work along Green Line).	**B5**
516	Build CTA park & ride, yard, shop at Maywood ComEd site and extend Blue Line. Connect to regional bus system.	**B2, C5, C11**
517	Blue Line extension to Mannheim Rd; new stations at Maybrook Courthouse, 17th Ave and Mannheim Rd; shuttle bus service to Loyola Medical Center and Hines VA [hospital].	**B2, C5**
518	Blue Line extension with north south circulators with interline connectors, employment center/hospital connectors.	**B2, C5**
519	Managed lanes-not new, but rather price all existing without add-a-lane. Blue Line extension west to I-290/I-294 "triangle". Peak period pricing on all existing I-290 lanes. Transit hub to interface with bus service at I-290/I-294 including potential DuPage J-Line operating Naperville/Oak Brook/Schaumburg alignment. Large park & ride facility with car share program in-place on-site. Rebuild I-290 without add-a-lane component.	**A4, B2, C11**
520	Extension of local service Blue Line. Phase 1 to include 4 additional stops to Mannheim Rd over capped landfill. Phase 2 continues connection to I-290, I-294, I-88 expressways with a park & ride oasis. Additional stations at 1st Ave, 17th Ave, 25th Ave and Mannheim Rd. Also renovate existing Des Plaines Ave station. [Also include a new multimodal transit station converting CN rail to express train at Austin Blvd - see Alt 29.]	**B2, B10, B11,**
521	See Cook DuPage [Corridor study] final system map, but limit Blue Line to Oak Brook area, e.g. I-290/I-294, not Lombard or even further west. Key elements: HRT in I-290 corridor, DuPage J-Line connect to HRT, add pricing on all I-290 lanes (existing) with no add-a-lane. Also N/S transit at Inner Circumferential [commuter rail] (25th) area. Rebuild I-290 without expansion.	**A4, B2, B10**
522	HOT lane w/bus (BRT) improvements. Use toll proceeds for transit improvements (extensions of Blue Line to 1st Ave with expanded parking and direct ramp access for parking and bus. Improve/rebuild existing Blue Line).	**A3, B2, B7, B11,**
523	Blue Line extension to 1st Ave with BRT access and park & ride; BRT in HOV lane of I-290/88 to Oak Brook; stations at logical cross arterials; BRT access to major activity centers in Oak Brook; integration with J-Line on west end.	**A2, B2, B7**
524	Extend Blue Line to Courthouse from Des Plaines Ave.	**B2**
525	Extend Blue Line to Oak Brook from Des Plaines Ave along I-290.	**B2**

ID #	Proposed Alternative Comment	Disposition
526	Extend Blue Line to Oak Brook from Des Plaines Ave along I-290. Stations at 1st Ave, 25th Ave, Mannheim Rd, Wolf Rd, York Rd, and Spring Rd.	**B2**
527	Extend Blue Line to Oak Brook with a shared station between 1st Ave and 5th Ave, and at 25th Ave and potential stations at Mannheim Rd and Wolf Rd.	**B2**
528	Extend Blue Line to 1st Ave from Des Plaines Ave.	**B2**
529	Extend CTA Blue Line to Oak Brook in I-290 and I-88 ROW. Under no circumstances should the Prairie Path be utilized.	**B2**
530	Extend the CTA Blue Line along I-290 to encourage better usage of the existing Blue Line capacity.	**B2**
531	Modern, fast, clean, state-of-the-art mass transit from Loop to Oak Brook. Fixed, not bus line. Along I-290 ROW.	**B2**
532	Extension should be a high speed, mass transit application. If new technology is appropriate use it - and replace aging Blue Line currently in place with newer technology. Whatever is built will be used for 60 to 100 years. It should be modern, clean and fast with good station accessibility and planned economic growth linked to the stations. Fixed tech - not bus. Along I-290 ROW.	**B2**
533	Extend Blue Line to Oak Brook along I-290 with key stations at 1st Ave, 25th Ave, and Spring Rd. Also add another rail line or ability to run "express" service between Oak Brook and downtown Chicago and O'Hare.	**B2, B4**
534	CTA Blue Line extension to Oak Brook from O'Hare along I-290 ROW. Stops at 1st Ave, 25th Ave, Wolf Rd, York Rd and Spring Rd. Tourists/visitors take Blue Line to Oak Brook hotels/shopping /entertainment center instead of staying in downtown Chicago. Tax revenue enhanced in DuPage County. A 1/4% tax on hotel stays is enacted to fund transit in the region.	**B2**
535	Extend CTA Blue Line to new terminal at 1st Ave using former Great Western ROW. Move CTA parking and yard/shop to new terminal. Keep existing CTA Des Plaines station, but redevelop remainder of property with T.O.D. This alternative frees up CTA ROW adjacent to I-290 between Des Plaines Ave and river crossing for roadway widening.	**B2**
536	Continue Blue Line to Wolf Rd. Add 5 stops with park & ride capacity. Stops at 1st Ave, 17th Ave, 25th Ave, Mannheim Rd then Wolf Rd.	**B2, C11**
537	Expand Blue Line through old RR ROW to west side of Des Plaines river. Build new transit multi-modal center at Maybrook Court facility. This will allow further expansion for BRT/other transit to the west.	**B2, C11**
538	Possible connection of CTA from Forest Park to [O'Hare] Airport.	**B2**
539	Use the old Great Western right-of-way thru Concordia Cemetery for CTA to access Maybrook Square and continue on Eisenhower west. This alternative is so burials would not have to be moved in cemeteries for widening of highway.	**B2**
540	Use Cook DuPage [Corridor study] Blue Line extension to Oak Brook.	**B2**
541	Blue Line extension (elevated structure) over Prairie Path (maintaining bike use) to Oak Brook via Butterfield Rd & I-88.	**B3**
542	Blue Line extension to Maybrook Courthouse; station at Maybrook Courthouse.	**B2**
543	Extending Blue Line to Maywood court house would alleviate multi-modal traffic issues by riders currently exiting at Forest Park when then have to bus to court house.	**B2**
544	Extend CTA BL to Maybrook Court via Maybrook Drive.	**B2**
545	I-290 Blue Line Extension [FP CTA to Il 83]	**B2**
546	I-290 Blue Line Extension [via I-290/ I88 ROW, FP CTA to Highland Ave]	**B2**
547	Blue Line extension via IPP, to co-exist with IPP [Illinois Prairie Path]. Begins at Des Plaines Ave, ends at Spring Rd in Oak Brook. Stations at 1st Ave, 25th Ave, Mannheim Rd, Wolf Rd, York Rd.	**B3**
548	Blue Line extension to Oak Brook via Prairie Path (maintain bike use) on elevated structure to Oak Brook activity centers adjacent along Butterfield Rd and arterials.	**B3**
549	Extend the CTA's Blue Line farther to the west to a destination spot, for example Oak Brook Terrace or Downers Grove. Create a north/south HRT, CR, or LRT line, maybe along I-355, to connect to existing single and multi modal transportation systems that lead to interior suburbs and the city of Chicago.	**B2**
550	Blue Line extension along I-290 [to I-88/I-290 split] at the edge of the ROW to avoid isolating stations in the middle of the expressway and making pedestrian, bus and bike access difficult. Also restructure local busing to serve HRT at O/D ends.	**B2**
551	More express buses from the west into Forest Park. Rush hour only.	**B15**
552	Express bus from/to 3 major locations.	**B15**
553	Have a dedicated express rail (CR and/or AGT / High Speed Rail). This would transfer auto trips from remote areas to express rail service with minimal stops. Should feature Chicago desired rail from O'Hare to [McCormick] Convention Center. [see Alternative 28 for recommended multi-modal transit station at Austin Blvd.] Collect I-290, I-294, I-88 at park & ride oasis. [see Alternative 28 for Blue Line extension, phase 1]	**B13, B16**
554	Abandon CTA ROW west of medical center (Ashland Ave). Build new transfer station for Illinois Medical District [IMD] and access to yard and shop at 54th.	**B12, C11**
555	Inner Circumferential Rail	**B10**
556	Prairie Path Realignment	**C3**
557	I-290 tolled facility with congestion pricing or peak hour tolling. Include I-55 in strategy.	**A4**
558	I-88/I-290 HOT Lanes [Cicero Ave to I-355] & Express Bus	**A3, B15**
559	I-290 BRT [Cicero Ave to Il 83] & HOV [Cicero Ave to I-88/I-290 split]	**A2, B7**

ID #	Proposed Alternative Comment	Disposition
560	I-290 BRT [1st Ave to Il 83], HOV [1st Ave to I-88/I-290 split] & Blue Line Extension to 1st Ave.	**A2, B2, B7**
561	Express bus using HOV/BRT lanes from Oak Brook to Chicago.	**A2, B7, B15**
562	BRT continues westbound from Forest Park Blue Line station. This option becomes viable with an additional managed/HOT lane. Also see relocation of Forest Park Blue Line terminal to west of river.	**A2, A3, B7**
563	Convert lane to managed lane. Lowest cost transit improvement. Upfront lease payment for 25 years of revenue collection.	**A2, A3**
564	Provide managed lane facility westbound from Circle interchange to I-294 / I-88. Provide managed lane facility eastbound from I-294/I-88 to Cicero Ave. Implement congestion pricing. Implement HOV preferences and Q-bypasses at Interchange. Tighten ramp metering; provide truck bypass and HOV bypass.	**A2, A3, C6, C11**
565	BRT in HOV lane in I-290/I-88 with direct (ramp/lane) access to Forest Park Blue Line; Oak Brook end includes access to major center(s) via arterial lanes; stations at logical major arterials/activity centers; integration with J-line on west end.	**A2, A3, B7**
566	I-290 HOV Lanes (2 + 1 on I-88) [Cicero Ave to I-88/I-290 split, split to IL ? Or I-355]	**A2**
567	In Oak Park section of the Ike [I-290], consider adding 2 lanes from Austin Ave to Harlem Ave by eliminating left hand ramps. Replace ramps with an elevated roadway connecting the 2 streets.	**A1, C2, C8**
568	Add managed lane. Convert lane 1 on I-88. Add managed lane on I-290. No free HOV passage. 25 year optional lease payment.	**A1, A3**
569	Managed lane network on regional expressways and tollways using a conversion of existing lanes in all locations (I-294, I-88, I-290) except along I-290 between Central Ave and 25th Ave where new construction would be necessary to add one managed lane in each direction. Access points at major roadway interchanges, including connection to Blue Line terminus at Des Plaines Ave or 1st Ave.	**A1, A2, A3, C5**
570	Add managed lane or convert existing lane with toll revenue used to fund transit improvements. Begin at Mannheim Rd and extend to Circle interchange.	**A1, A2, A3**
571	WCMC Letter. The WCMC would encourage IDOT to utilize a multimodal approach when exploring all possibilities beyond the traditional roadway approach. We hope that a roadway expansion will only be considered as a last resort or as supplemental to a reasonable transit option prior to disturbing the land use of one of our communities. The Cook DuPage Corridor Study has closely reviewed potential alternatives to improve traffic flow along the Eisenhower. We hope that the work completed during this study will be given due consideration during this Pahse I study.	**B2**
572	In summary, I-290 should not expand the number of lanes, pon/off ramps should remain as is, public transit should be increase i.e CTA Blue Line extension/expansion, increase in bus and Metra services, regional trnasportation hub to be expanded /developed, increasing transit	**B2, B9, C5, C11**

N

*Not to scale

DESCRIPTION:

> Elevated CTA Blue Line extension via Illinois Prairie Path and Butterfield Road (IL 56).
> 7.6 miles

TRANSIT SERVICE ENHANCEMENTS:

> Added 7 New Blue Line stations: 22nd Street, Roosevelt Road, York Road, Wolf Road, Mannheim Road, 25th Avenue and 1st Avenue.

TRANSIT SERVICE ENHANCEMENTS: *(con't)*

> Added 11 new stops at new stations on routes: CTA Bus Route #17, Pace Bus Routes # 301, #310, #317, #325, #330, #331, #332, #747, #877, and #888.
> Rerouted Pace Bus Route #331 from 5th Avenue to 1st Avenue station.
> Truncated Pace Bus Route #747 to new station at York Road.
> Optimized 2 existing Pace express bus routes to provide express shuttle service: #877 and #888.
> Included future Pace Bus Route art89 along Cermack Road (Yorktown to CTA Pink Line) and Pace feeder bus route on Roosevelt Road to Roosevelt Station.

Blue Line I-290 > Blue Line Extension from Forest Park CTA Terminal to Oak Brook

ID: HRT 2

N

*Not to scale

DESCRIPTION:

> Via I-290 median (at-grade) from CTA Forest Park Terminal to Mannheim Road.
> Adjacent to I-290 (elevated), adjacent to I-88 (elevated), and adjacent 22nd Street (elevated) from Mannheim Road to Oak Brook (IL 83).
> 8 miles

TRANSIT SERVICE ENHANCEMENTS:

> Added 6 New Blue Line stations: 22nd Street, York Road, Wolf Road, Mannheim Road, 25th Avenue and 1st Avenue.

TRANSIT SERVICE ENHANCEMENTS: *(con't)*

> Added 12 new stops at new stations on routes: CTA Bus Route #17, Pace Bus Routes # 301, #310, #317, #325, #330, #331, #332, #747, #757, #877, and #888.
> Rerouted existing Pace Bus Route #331 from 5th Avenue to 1st Avenue station.
> Truncated 3 existing bus routes to new terminal stop: #391and #757 to Wolf Road station and #747 to York Road station.
> Optimized 2 existing Pace express bus routes to provide express shuttle service: #877 and #888.
> Included future Pace Bus Route art89 along Cermak Road (Yorktown to CTA Pink Line).

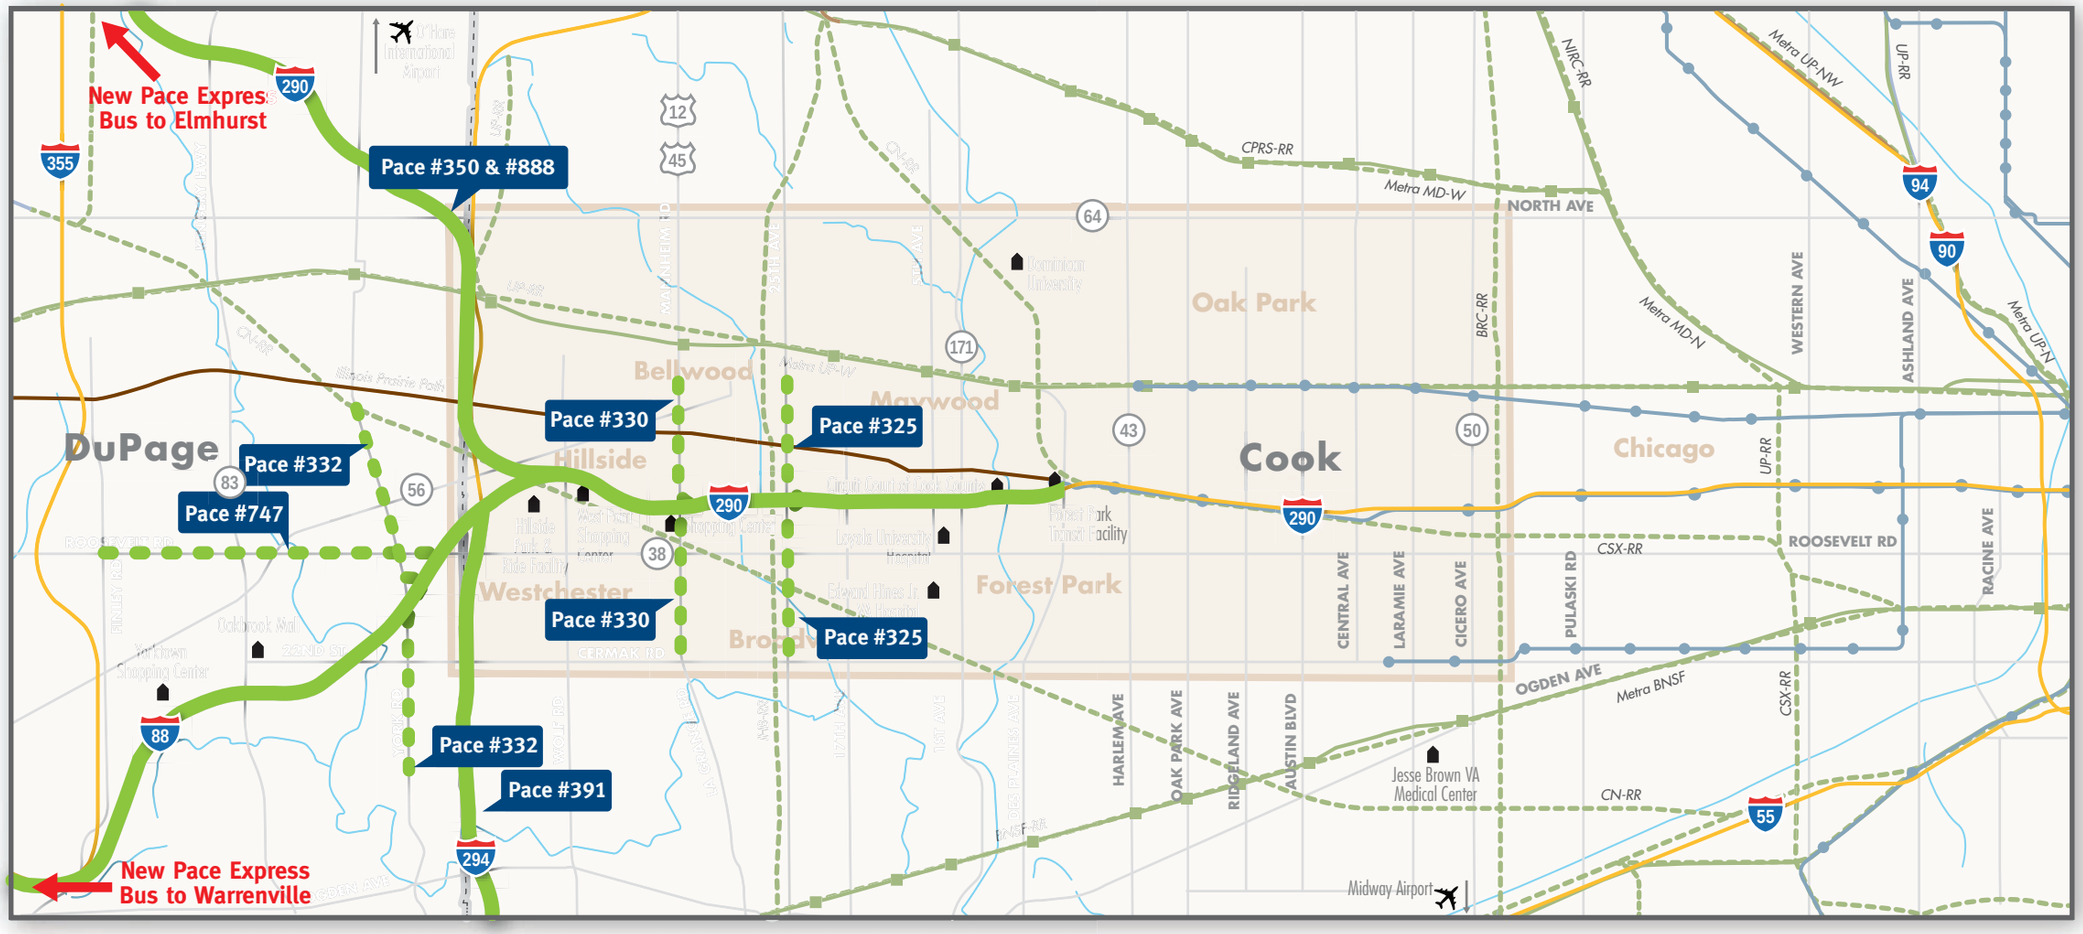
Blue Line I-290 > Blue Line Extension from Forest Park CTA Terminal to Mannheim Road

ID: HRT 3 | Heavy Rail Transit (HRT)

DESCRIPTION:

> Via I-290 Median (at-Grade) from CTA Forest Park terminal to Mannheim Road.
> 3.5 miles

TRANSIT SERVICE ENHANCEMENTS:



> Added 3 New Blue Line Stations: Mannheim Road, 25th Avenue and 1st Avenue.
> Added 10 new stops at new stations on routes: CTA Bus Route #17, Pace Bus Routes #317, #325, #330, #331, #391, #747, #757, #877, and #888.

TRANSIT SERVICE ENHANCEMENTS: *(con't)*

> Rerouted existing Pace Bus Route #331 from 5th Avenue to 1st Avenue station.
> Truncated 6 existing bus routes to new terminal stop: #317, #391, #747, #757, #877 and #888 to Mannheim station.
> Optimized 2 existing Pace express bus routes to provide express shuttle service: #877 and #888
> Included future Pace Bus Route art89 along Cermak Road (Yorktown to CTA Pink Line)

Alternative

- Add Lanes
- Toll Lanes

N

*Not to scale

DESCRIPTION:

> Toll I-290 lanes from I-88/290 split to Cicero Avenue.
> Add 2 lanes (1 in each direction) along I-290 from I-88/290 split to Central Avenue.
> 8.5 miles

I-290 Phase I Study

Round 1 - Alternatives Footprint Evaluation (West of the DesPlaines River)

September 29, 2011

DRAFT

NOTE: Alternative impacts in this table are for the portions of the alignments that lie west of the DesPlaines River. Alternative footprints east of the River cannot be determined at this time due to locational variability of alignments associated with the availability of CSX or CTA ROW, and the use of context sensitive design. Impacts in this area will be evaluated when the availability of railroad ROW is determined.

(1) - Crash totals are for injury and fatal crashes only

(2) - Length based average

(3) - Person miles are calcuated using the CMAP regional travel model for each alternative

Initial Alternatives Identification and Evaluation Report

November 2011

APPENDIX E

Single Mode Alternatives Footprint Evaluation

I-290 Phase I Study

Round 1 - Alternatives Footprint Evaluation (West of the DesPlaines River)

September 29, 2011

DRAFT

NOTE: Alternative impacts in this table are for the portions of the alignments that lie west of the DesPlaines River. Alternative footprints east of the River cannot be determined at this time due to locational variability of alignments associated with the availability of CSX or CTA ROW, and the use of context sensitive design. Impacts in this area will be evaluated when the availability of railroad ROW is determined.

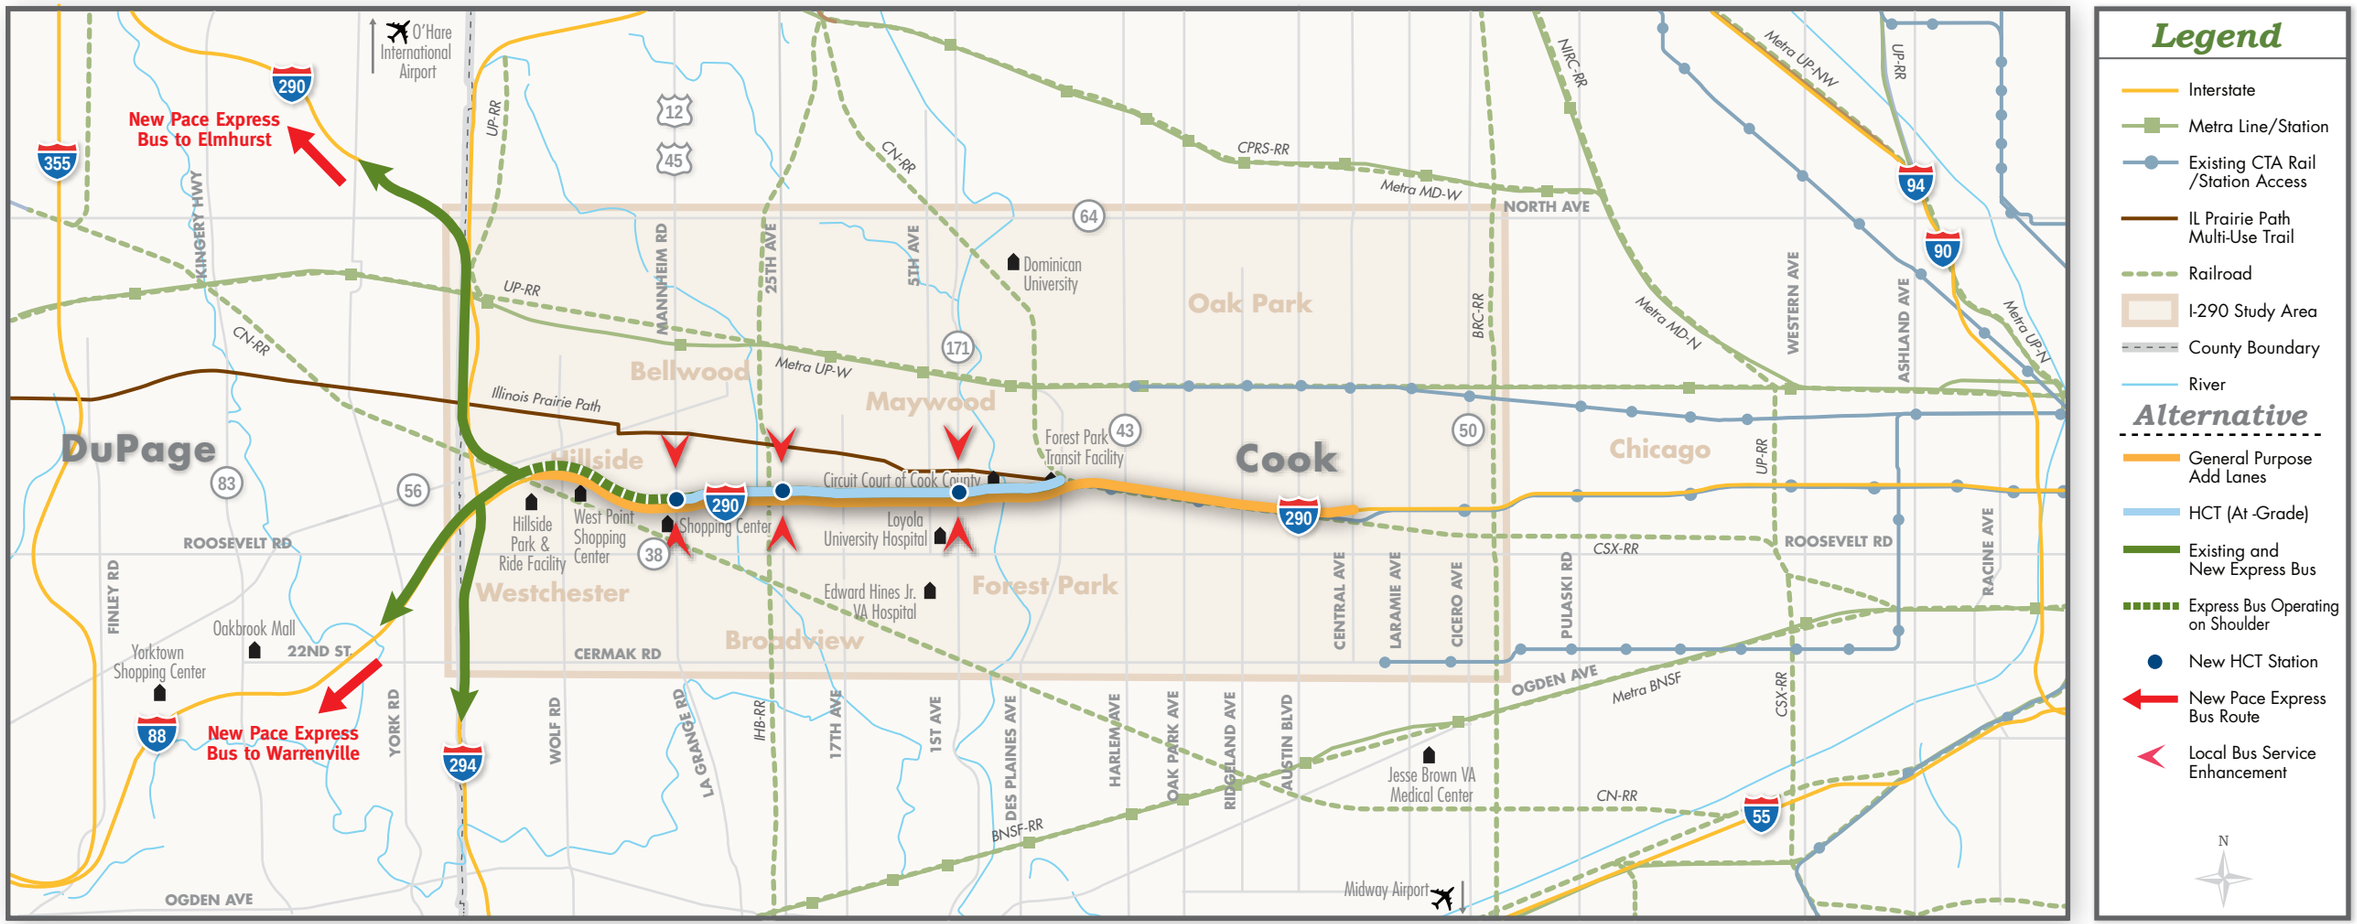
- Metra Line/Station
- Existing CTA Rail /Station Access
- IL Prairie Path Multi-Use Trail
- Railroad
- I-290 Study Area
- County Boundary
- River

Alternative

- General Purpose Add Lanes
- Express Bus Operating on Shoulder
- New Pace Express Bus Route

N



GP Lanes

> Add 2 Lanes (1 in each direction) along I-290 from I-88/290 Split to Central Avenue.
> 7.5 miles

Express Bus:

> Express Bus Service on I-88 & I-290 to CTA Forest Park Terminal.
> Enhanced local bus routes to run express to CTA Forest Park Terminal.
> Express Bus service to use I-290 Shoulder.

GP + HCT + EXP > General Purpose Add Lane & High Capacity Transit & Express Bus Service

Legend

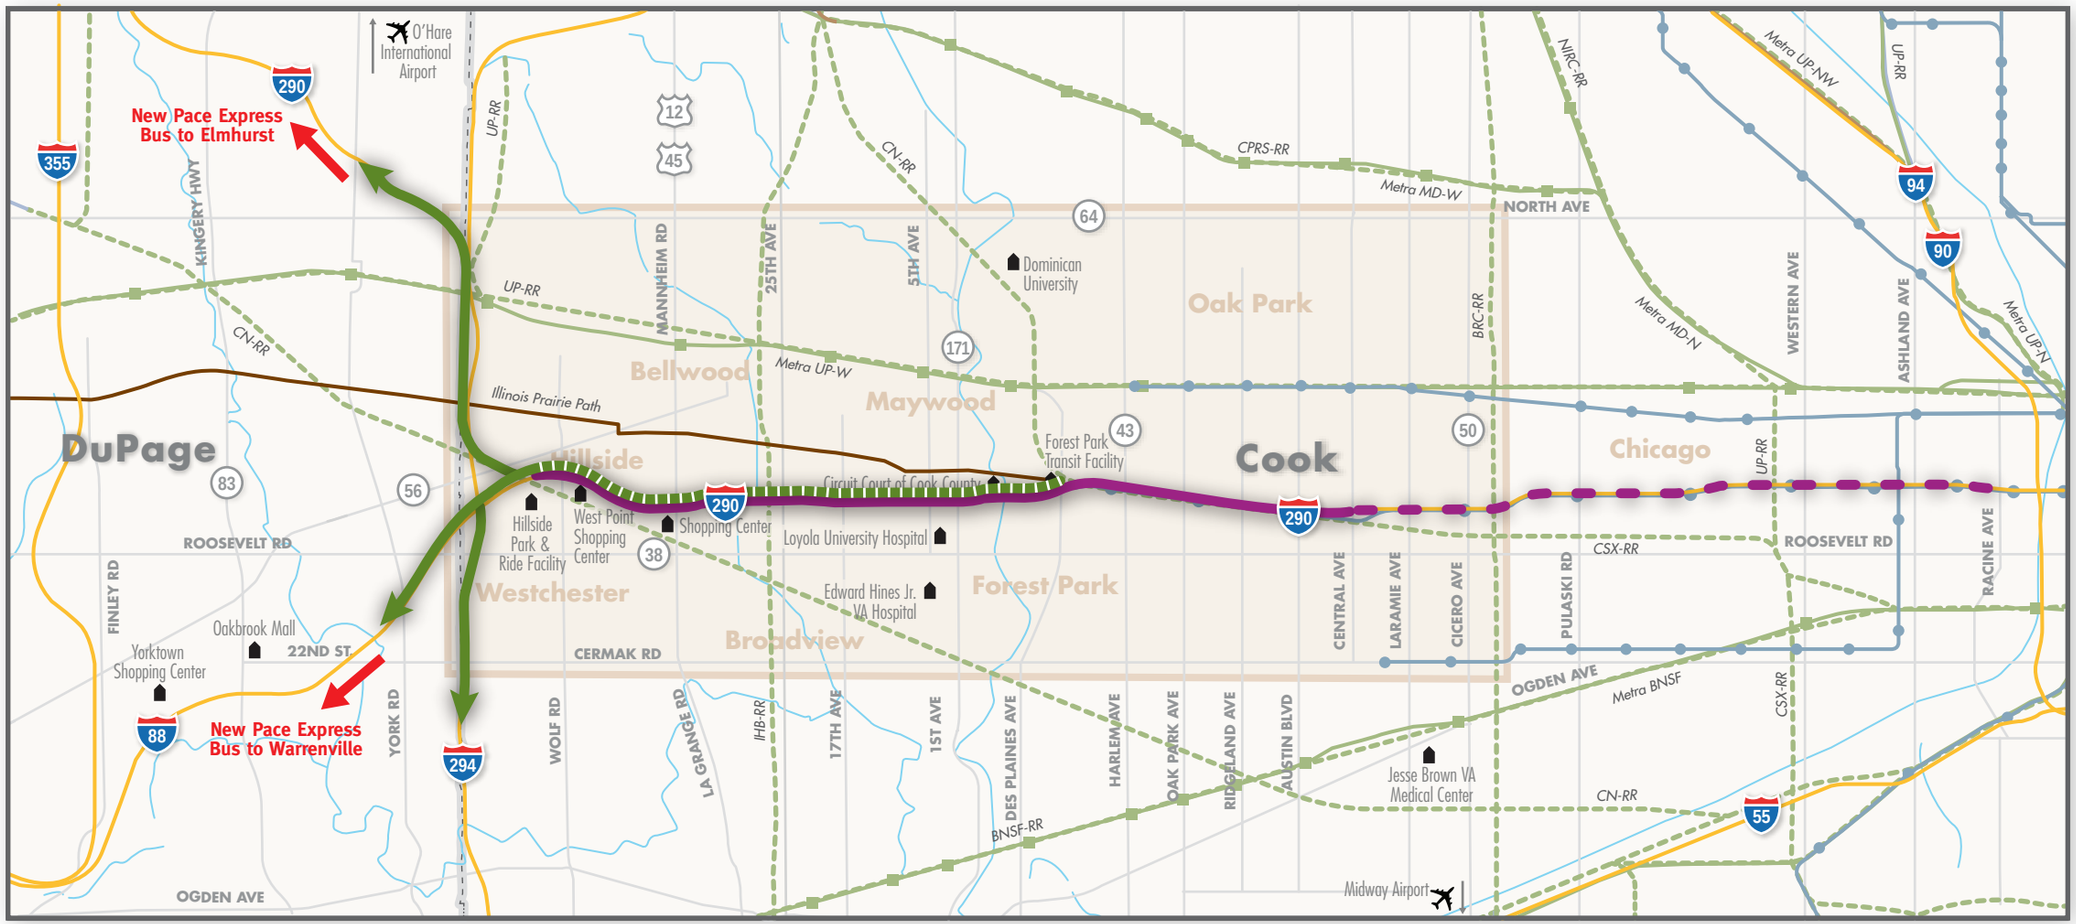
- Interstate
- Metra Line/Station
- Existing CTA Rail /Station Access
- IL Prairie Path Multi-Use Trail
- Railroad
- I-290 Study Area
- County Boundary
- River

Alternative

- General Purpose Add Lanes
- HCT (At -Grade)
- Existing and New Express Bus
- Express Bus Operating on Shoulder
- New HCT Station
- New Pace Express Bus Route
- Local Bus Service Enhancement

N

*Not to scale



GP Lanes:
> Add 2 Lanes (1 in each direction) along I-290 from I-88/290 Split to Central Avenue.
> 7.5 miles

High Capacity Transit (HCT):
> HCT as Blue Line Extension (HRT) or Bus Rapid Transit (BRT).
> Add HCT from CTA Forest Park Terminal to Mannheim Road in I-290 Median.

High Capacity Transit (HCT): *(con't)*
> 3 New HRT/BRT stations – Mannheim Road, 25th Avenue, 1st Avenue.
> 3.5 miles

Express Bus:
> Express Bus Service on I-88 & I-290 to CTA Forest Park Terminal.
> Enhanced local bus routes to run express to CTA Forest Park Terminal.
> Express Bus service to use I-290 Shoulder.

HOV + EXP > High Occupancy Vehicle Lanes (HOV) 2+ Occupants & Express Bus Service

*Not to scale

Legend

- Interstate
- Metra Line/Station
- Existing CTA Rail /Station Access
- IL Prairie Path Multi-Use Trail
- Railroad

> Toll existing lanes from I-290/I-88 Split to Racine Avenue.
> 13 miles

High Capacity Transit (HCT):

> HCT as Blue Line Extension (HRT) or Bus Rapid Transit (BRT).
> Add HCT from CTA Forest Park Terminal to Mannheim Road in I-290 Median.
> 3 New HRT/BRT stations – Mannheim Road, 25th Avenue, 1st Avenue.
> 3.5 miles

Express Bus:

> Express Bus Service on I-88 & I-290 to HRT/BRT Mannheim Station.
> Enhanced local bus routes to run express to HRT/BRT Mannheim Station.
> Express Bus Service to run on HOT Lanes at no charge.

Round 2 Combination Mode Alternatives

Initial Alternatives Identification and Evaluation Report

April 2013

APPENDIX H

Travel Forecasting Assumptions

Purpose

The purpose of this summary is to present the travel forecasting assumptions being used by IDOT for the I-290 Environmental Impact Statement (EIS). In addition, a comparison of any differences in assumptions being used by CMAP for the development of their GO TO 2040 Comprehensive Regional Plan and the Cook-DuPage Corridor Study is also included, as well as a discussion of how the GO TO 2040 Plan and forecasts will be considered as part of the I-290 Study. The I-290 Study has previously documented its travel forecasting approach. The "I-290 Travel Model Assumptions Methodology & Validation" report (July 2010) was prepared and is posted on the I-290 project website (www.eisenhowerexpressway.com). CMAP has prepared "CMAP Travel Demand Model Validation Re port" (February 23, 2011), which documents their regional travel forecasting process and is available on their website (www.CMAP.illinois.gov). In summary, a project level forecast is required for the I-290 Study:

- To satisfy the requirements of National Environmental Policy Act (NEPA)
- To provide the appropriate level of engineering and environmental detail
- To account for differing infrastructure assumptions for the no build and build scenarios
- To properly disclose and measure project impacts.
- To provide tolling forecasts that are consistent with national industry standards

Why develop a project level forecast?

GO TO 2040 and NEPA studies are produced for different purposes

As part of the Clean Air Act Amendments and past Federal transportation authorizations up to and including Moving Ahead for Progress in the 21st Century (MAP-21), metropolitan areas over 50,000 in population must develop regional long range transportation plans. These plans are intended to guide public policy with respect to future land use and infrastructure investment for the next 20+ years for the region. GO TO 2040 is intended to identify an overall framework of major capital projects that are tested for air quality conformity and are within an assumed overall fiscally constrained scenario. The projects identified as part of the GO TO 2040 process essentially represent placeholders that are subject to NEPA studies, including a rigorous analysis of alternatives. GO TO 2040 does not, however, satisfy all of NEPA's planning requirements for implementing an infrastructure project.

As required by NEPA, a major infrastructure project such as I-290 is required, at a project level of detail, to undergo:

- An analysis of a "No Build" alternative to define the transportation need. For the I-290 study, the "No Build" is defined as no major improvements in the study area; outside the study area, the major capital improvements contained in GO TO 2040 are assumed to be in place.

- An analysis of a range of reasonable Build alternatives. As documented in the ongoing I-290 study, a broad range of multimodal (highway/transit combinations) alternatives are being evaluated.
- An assessment of the social, economic, and environmental impacts of a proposed action or project. The I-290 study will include an analysis of noise, air quality, energy, threatened & endangered species, natural resources, wetlands, floodplains, water resources, groundwater resources, Section 4(f) properties/parks and recreation, special/hazardous waste, special lands, social and economic impacts including environmental justice, cultural resources, visual resources, indirect and cumulative impacts, and construction impacts.
- Consideration of environmental sequencing: avoidance, minimization and mitigation.
- Stakeholder involvement: coordination and consultation on every aspect of the NEPA process, including the identification of project needs, evaluation methodologies, and alternatives development and evaluation.

NEPA requires preparation of an EIS for major Federal actions that may significantly affect the quality of the human environment. An EIS is a full disclosure document that details the process through which a transportation project was developed, includes consideration of a range of reasonable alternatives, analyzes the potential impacts resulting from the alternatives, and demonstrates compliance with other applicable environmental laws and executive orders. IDOT and FHWA will be preparing an EIS for the I-290 Study.

GO TO 2040 and NEPA studies differ in scale and level of detail

Regional Long Range Transportation Plans – For CMAP, a seven-county northeastern Illinois region is evaluated; the regional transportation network covers 23 counties in three states; this regional modeling platform yields broad measures of performance, such as total auto and transit trips, average travel time, and hours of congestion. To evaluate this project in a regional context using its standard travel demand model, CMAP codes a managed lane as equivalent to 0.33 lane additional capacity. Standard travel models cannot effectively evaluate managed lane operations or congestion pricing.

NEPA / Project Level Studies – Require a greater level of travel modeling detail for use in design, environmental impact evaluation, and financial analysis. NEPA / Project Level Studies typically use a focused area modeling approach where the regional model is detailed in the project study area. This involved developing a finer level of detail for the roadway network in the study area. The I-290 Study also implemented additional modeling enhancements to better analyze the alternatives under consideration, including modeling procedures to estimate auto occupancy in order to evaluate HOV alternatives, tolling procedures to evaluate toll and HOT alternatives, transit model improvements to evaluate transit alternatives, and detailed travel performance measures, such as person throughput, study area expressway and arterial performance, and truck and transit measures. The travel model enhancements developed for the I-290 Study are presented in the attached table.

GO TO 2040 and NEPA studies differ in transportation infrastructure assumptions for "Build and No Build"

During 2008, while GO TO 2040 was in its early development, CMAP used a "Reference Scenario" as a baseline to evaluate over 100 proposed major capital improvements. Because the policy direction of GO TO 2040 had not yet been established, the Reference Scenario assumed continuation of current socioeconomic and land use trends and no additional transportation infrastructure in 2040. In 2010, CMAP officially adopted GO TO 2040 which includes a "Preferred Scenario" that promotes infill and reinvestment as the primary policy driver for future land use planning and transportation investment. The Preferred Scenario integrates socioeconomic and land use assumptions with a fiscally constrained set of transportation improvements intended to support specific planning goals. In the Preferred Scenario, CMAP assumes an I-290 managed lane from Mannheim to Cicero, but no CTA Blue Line extension, in the list of fiscally constrained transportation projects. The I-290 NEPA study tests and refines the original project specification to achieve better performance and recognize specific construction and operational constraints.

As prescribed by NEPA, IDOT excludes all major capital projects in the study area to determine "No Build" conditions. The No Build alternative serves as a benchmark against which the transportation needs are defined and the Build Alternatives are compared. For the I-290 study, the No Build alternative includes all of the major capital projects included in fiscally constrained GO TO 2040 Plan *except* the proposed I-290 Multimodal Corridor project. The I-290 project also employs an updated version of the Reference Scenario by assuming that socioeconomic and land use patterns are the product of market-driven trends rather than the policy driven integrated land use and transportation scenario found in the GO TO 2040.

The Build alternatives for the I-290 Study are combinations of highway and transit improvements, including managed lanes, the Blue Line Extension, and other transit, highway, and non-motorized improvements. As such, the Build alternatives that advance to the Draft Environmental Impact Statement (DEIS) will each require a Build socioeconomic forecast. Further coordination with FHWA and CMAP is necessary to address the need to develop multiple build forecasts and the role of the GO TO 2040 preferred scenario forecast.

What are the specific differences between GO TO 2040 and I-290 forecasting approaches?

2040 Population and Employment Forecasts

As part of the GO TO 2040 Comprehensive Regional Plan process, CMAP developed population and employment forecasts that reflect the desired outcome of the plan. As part of CMAP's mandate to integrate land use and transportation planning, the method used to develop the 2040 population and employment forecasts is a radical departure from previous practices in the region. Prior to GO TO 2040, regional planning practice in northeastern Illinois was based on municipal and county consultation, historic trends, local land use policies, local development proposals, available land for development, and county level control totals. This socioeconomic and land use forecast was adopted as the planning

baseline for major project development under the separately developed Regional Transportation Plan (RTP).

CMAP's approach for the GO TO 2040 Plan was to integrate land use and transportation policy using a scenario-driven 2040 population and employment forecasting technique systematically responsive to major investments and high-level choices that shape the region. The scenario-driven forecasts reflect the plan's desired scenario outcome (i.e. the Preferred Scenario) and assume that the recommended policies will be in place by 2040 in order to achieve these.

Since the late 1990's, a court ruling (Sierra Club, et al v. U.S. Department of Transportation, et al, January 16, 1997, No. 96 C 4768) has required inclusion of No Build and Build Scenario evaluations for major project development. IDOT has coordinated with CMAP on performing No Build and Build analyses that forecast alternative development patterns and travel behavior that might result from a major new transportation project. It is instructive to recognize that actual socioeconomic and land use outcomes are a combination of policy- and market-driven economic forces. In reality, public policy only redirects market-driven land development. A market-based economic forecast alternative can also aid detailed NEPA level project development in determining the sensitivity of proposed highway and transit facility performance and environmental impacts under different background assumptions. Also, any potential toll and revenue evaluations needed to finance a project will require that an investment-grade forecast be prepared. Lenders and bonding agencies are typically reluctant to assume that goal-based policy-driven recommendations will be entirely effective in the face of *laissez-faire* market economics. Tolling options are being considered as part of the I-290 Study, and similar market-based economic forecasts are also being used by the Illinois Tollway for their major project development studies. Similarly, the Federal Transit Administration now places more emphasis on models that replicate current year demand and existing land use as the basis for forecasting eligibility for New Starts funding.

IDOT has developed a market-based economic forecast for this study. This No Build market-based economic forecast does not assume the implementation of the I-290 Multimodal Corridor project, but includes implementation of the fiscally constrained projects outside of the study area. The I-290 Study No Build forecasts maintain the same control totals for the region as GO TO 2040, but have a different distribution of population and employment within the region that more closely resembles the Reference Scenario.

CMAP anticipated and supports the need for alternative socioeconomic forecasts to evaluate major projects as outlined in CMAP's Forecasting Principles. IDOT consultants have closely coordinated with CMAP staff on development of the I-290 market-based economic forecasts, consistent with the CMAP forecasting principles, and CMAP staff concurs on the method used to develop them.

The I-290 Study is using market-based economic forecasts for the No Build scenario 2040 population and employment forecasts. The I-290 Study population and employment forecasts are based on historic trends, 2010 Census data, land availability, local land use policies, and independent Woods & Poole county level economic forecasts. Note that the resulting population and employment forecasts for the I-

290 Study are based on different forecasting assumptions than GO TO 2040 Plan, which were scenario derived, policy-based forecasts. The I-290 Study No Build market-based population and employment forecasts do not contain the same policy assumptions as the CMAP forecast, and are more consistent with the detail and assumptions typically used to initiate project level design, environmental, and financial evaluations.

A comparison of the existing 2010, CMAP GO TO 2040 Plan, and I-290 Study 2040 No Build population forecasts for Cook and DuPage Counties is presented in the following table. The difference between the 2040 population forecasts from the I-290 Study and the CMAP GO TO 2040 Plan reflects the level of policy and directed investment assumed in the GO TO 2040 Plan policy goals. For Cook County, there is an 8% difference between the 2040 GO TO 2040 population total and the I-290 Study. For DuPage County, there is a 14% difference between the 2040 CMAP GO TO 2040 population and the I-290 Study. This is largely the result of accommodating new growth within existing communities instead of converting vacant or agricultural land at the region's fringe to urban use.

Population Forecast Comparison

County	2010 Population (Census)	2040 CMAP GO TO 2040 Population Forecast	2040 I-290 Study No Build Population Forecast
Chicago	2,695,934	3,303,768	3,000,996
Suburban Cook	2,499,365	2,935,429	2,773,534
Total Cook	5,195,299	6,239,197	5,774,530
DuPage	916,924	1,160,364	1,022,204

The I-290 Study will also develop 2040 Build population and employment forecasts that will be used to test the final Build alternatives being evaluated in the DEIS. The I-290 2040 Build population and employment forecasts will use the 2040 I-290 No Build population and employment forecasts as a starting point and then revise the forecasts based on the increased accessibility provided by the transportation improvements included in the Build alternatives. Given the need to develop multiple build forecasts for the Draft EIS alternatives, further coordination is required with FHWA and CMAP to develop a methodology for producing them and determining the role of the GO TO 2040 forecast in that process.

Highway and Transit Network Assumptions

The I-290 Study utilized the CMAP GO TO 2040 Plan highway and transit networks as a starting point to develop the No Build scenario transportation networks. Thus, major capital projects contained in the fiscally constrained GO TO 2040 Plan were included in the networks, with the exception of the I-290 Multimodal Corridor project. In addition, the background transit service enhancements included in the fiscally constrained GO TO 2040 Plan, such as implementation of arterial rapid transit, and other bus enhancements were included in the I-290 Study transit network. Thus, these background transit improvements contained in the GO TO 2040 Plan, such as the Cermak Road arterial rapid transit (bus rapid transit) service, are included in the 2040 I-290 transit network for all alternatives tested.

For the development and testing of transit alternatives in the I-290 Study, the CTA Blue Line extension, bus rapid transit, and express bus alternatives were coded on top of the background transit network. The I-290 transit alternatives included the addition of new terminal and intermediate stations for the Blue Line extension and bus rapid transit alternatives, the availability of park-and-ride at outlying stations (Mannheim Road and stations to the west), feeder bus connections for existing bus routes, and additional new (or restored) feeder bus service. The attached map depicts the transit network improvements for the testing of the Blue Line extension to Oak Brook via I-290 as part of the Single Mode testing.

For the I-290 Study, additional detail was also included in the study area for the coding of I-290 in order to better reflect actual movements. The use of auto occupancy and toll modeling procedures also required more detailed coding of I-290. On the transit side, minor revisions were made to the transit network and processing of the network to better replicate existing transit travel patterns in and near the study area. This included improving the split between forecasted Metra and CTA rail ridership.

Travel Model Enhancements

Throughout the I-290 Study, the travel demand forecasting approach and implementation has included continuous coordination and cooperation with CMAP. When the I-290 Study was initiated in 2009, the CMAP regional travel model and the 2030 Regional Transportation Plan assumptions were used as the starting point. With the adoption of CMAP's GO TO 2040 Comprehensive Regional Plan in October 2010, the travel modeling for the I-290 Phase I Study transitioned to using CMAP's GO TO 2040 forecasts.

Over the course of the I-290 Study, IDOT's consultant has implemented a number of enhancements to the CMAP regional travel model, which have in turn been adopted by CMAP. There were three major reasons for developing and implementing these CMAP regional travel model enhancements:

- To update the CMAP regional travel models using data from the 2007 CMAP Travel Tracker Survey, the American Community Survey (ACS) and the 2010 Census.
- To develop and implement more detailed travel forecasting procedures and inputs for use in the development of design-level traffic forecasts for major project development, and
- To develop enhanced travel forecasting procedures to provide improved sensitivity to the alternatives being tested.

IDOT's consultant has coordinated closely with CMAP staff as part of implementing these model improvements. The I-290 Study travel model improvements were developed by Parsons Brinckerhoff staff with extensive experience working directly with the CMAP regional travel model.

The attached table summarizes the regional travel model enhancements implemented for the I-290 Study. As seen in this table, there have been a long series of travel model enhancements made for the I-290 Study as additional needs arise. Many of these travel model enhancements have since been

integrated into the CMAP regional travel forecasting process.

Can you compare CMAP's results for I-290 and the Blue Line extension in GO TO 2040 with IDOT's current I-290 study?

I-290 Results

The modeling results for an I-290 managed lane improvement are not comparable. GO TO 2040 did not use any auto occupancy or tolling procedures in their regional modeling. The I-290 managed lane project was represented by increasing capacity on I-290 by an additional third of a lane in each direction to approximate the additional traffic that would use the managed lane. Therefore, this added capacity which is supposed to act as an HOV/HOT lane, is essentially represented by an increase in capacity of the general purpose lanes. The additional one-third of a lane capacity is intended to represent the magnitude of the additional HOV/HOT vehicles that would be using the managed lane. For the purposes of regional long range transportation plan project analysis and regional air quality conformity analysis, this is an acceptable approach.

The I-290 Study, since it is a NEPA/project level analysis, is using auto occupancy and tolling procedures to provide a more causal representation of travel behavior associated with managed lanes. Thus, the model estimates single occupant, 2-person, and 3+ person auto vehicle trips, as well as reflecting the impact of tolls, including mode shifts from auto to transit as a result of tolling. This additional level of analysis detail is required for development of project level design, environmental, and financial measures.

Blue Line/HCT Extension Results

The modeling results for a transit extension of the Blue Line to Oak Brook are more comparable, since CMAP regional transit modeling procedures were used for GO TO 2040 and the I-290 Study. The "GO TO 2040 Major Capital Projects" (originally drafted February 2010; updated October 2010) shows a Blue Line extension resulting in +4,000 transit trips and -3,000 auto trips. In the Round One Single Mode Screening analysis in the I-290 Study, the Blue Line Extension to Oak Brook resulted in +8,400 transit and -8,400 auto trips. Thus, even using a 2040 No Build market-based population and employment forecast in the I-290 Study, the Blue Line extension resulted in double the auto diversion, and higher ridership than in GO TO 2040.

Role of GO TO 2040 Comprehensive Regional Plan goals in the I-290 NEPA study

The GO TO 2040 Plan identified improvements in the I-290 corridor that met the broad goals of GO TO 2040, including conformity with regional air quality standards. For the purposes of the I-290 NEPA study, our purpose and need has and will continue to be related to those goals, including:

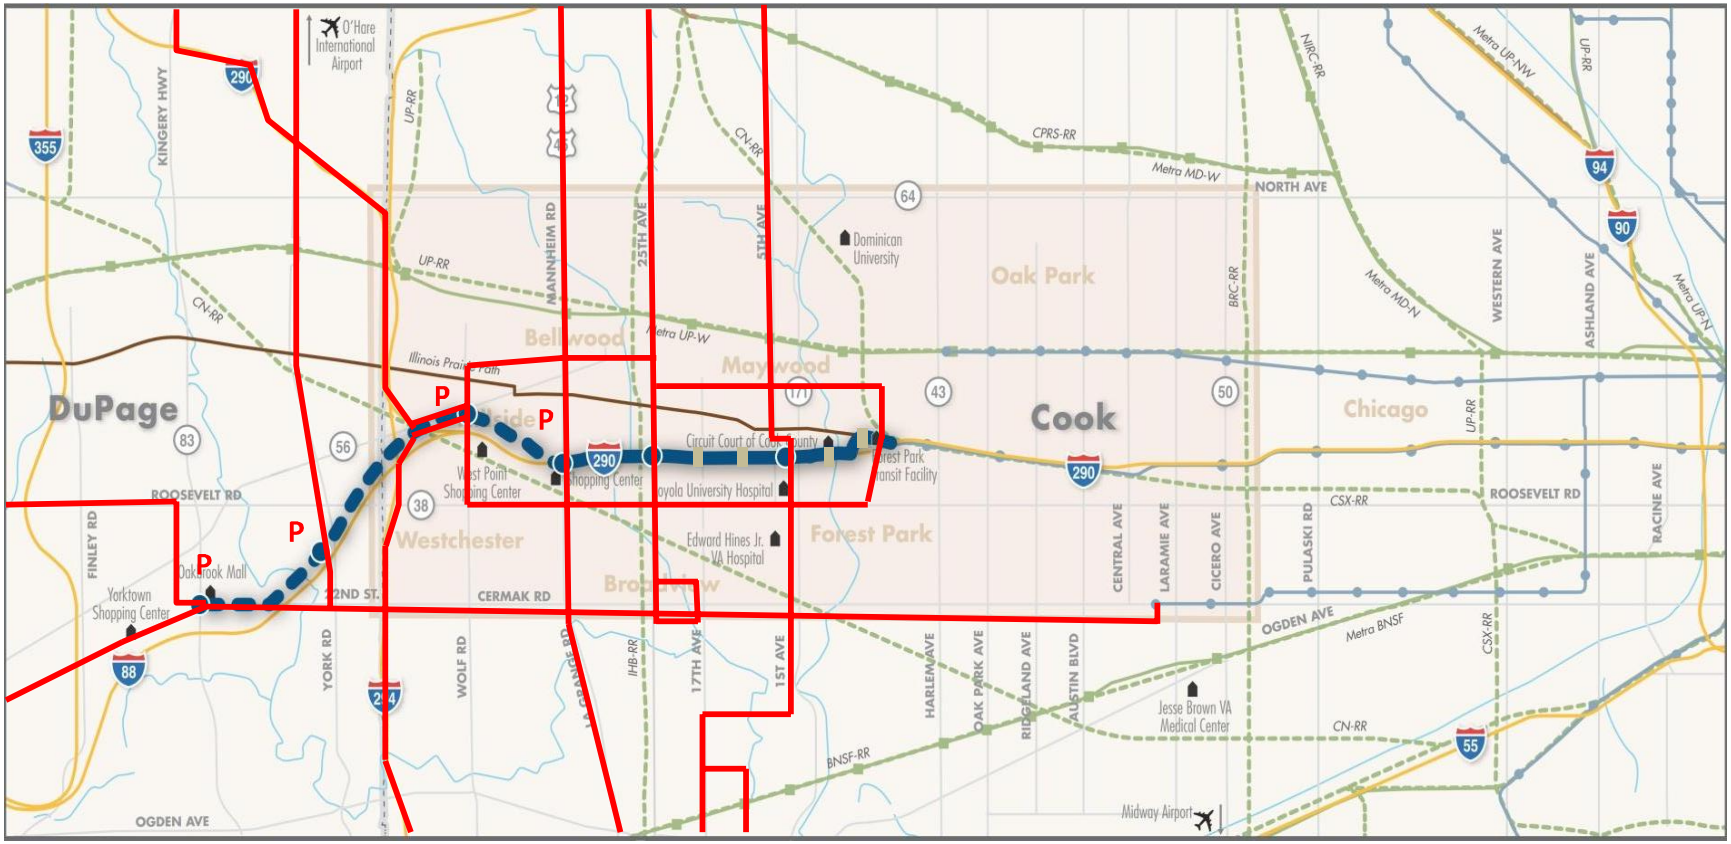
- Improve regional and local mobility – Directly related to GO TO 2040 congestion evaluation measures, including speeds, travel times and hours of congestion

- Improve accessibility to employment – Directly related to GO TO 2040 jobs-housing access evaluation measure
- Improve safety for all users – Safety is a paramount goal for any transportation project
- Improve modal connections and opportunities – Directly related to GO TO 2040 mode share evaluation measure
- Improve facility deficiencies – Directly related to GO TO 2040 facility condition evaluation measure

Furthermore, the I-290 DEIS will address in a much greater level of detail the socio-economic and environmental impacts/benefits of the finalist build alternatives.

In addition, a comparison between the GO TO 2040 Preferred Scenario and the I-290 NEPA study forecasts will be included in the Draft EIS. The eventual preferred alternative, which will be identified in the Final EIS, will include a discussion of how it is consistent with the GO TO 2040 Plan.

Summary



A project level forecast is needed in order to provide a sufficient level of engineering and environmental detail, to account for differences in infrastructure assumptions, and in doing so, satisfy NEPA requirements. CMAP has anticipated the need for alternative forecasts for project level development by issuing their "CMAP Forecast Principles for Data Users and Forecast Developers," and IDOT has coordinated with CMAP in developing I-290 market-based economic forecasts, for which CMAP has concurred with the methodology used to develop these forecasts.

The requirement for more detailed NEPA project level forecasts for the I-290 Study also led to more detailed highway and transit networks and processing in the study area. Furthermore, additional travel model enhancements were made for the I-290 Study to better model managed lane alternatives and to better replicated study area travel patterns. The model enhancements made by IDOT have been/will be incorporated back into CMAP's regional model.

The overall results in testing of the I-290 managed lane in GO TO 2040 versus the I-290 Study are not comparable, since GO TO 2040 did not use auto occupancy or tolling procedures to model the I-290 improvements. With regards to the Blue Line extension, the I-290 Study resulted in double the auto diversion and higher ridership than GO TO 2040.

Travel Forecasting Comparison Table

Attributes or Assumptions	CMAP GO TO 2040 2008 Evaluation	IDOT I-290 EIS Model 2012 Evaluation	Comments
2040 Base Line Projects Assumed in Transportation Networks	CMAP 2040 fiscally constrained major projects and background bus and arterial projects included.	Starting point is the same 2040 CMAP transportation network minus the I-290 Multimodal Corridor Managed Lane Project.	To create 2040 I-290 "No-Build" alternative scenario used for comparison of conditions with and without an improvement. Required practice for EIS and accepted by CMAP.
2040 Socioeconomic Forecasts	Based upon CMAP GO TO 2040 Preferred Regional Scenario (developed prior to 2010 Census results).	2040 No-Build forecast developed by Consultant Team (developed after 2010 Census results) based on CMAP regional control totals. 2040 Build forecast to be developed by Consultant Team for use in DEIS.	CMAP developed only 2040 Preferred Regional Scenario. Preferred Regional Scenario developed as a scenario-driven policy-based 2040 forecast for addressing major investments and high-level choices that shape the region. The forecast reflects the desired plan scenario outcome and assumes that the recommended policies will be in place by 2040. The I-290 2040 No Build forecast were based on historic trends, land availability, and independent Woods & Poole county level forecasts and match the population totals used for GO TO 2040. Market based forecast approach is typical practice for design and financial analysis purposes for major project development. 2040 Build forecast to reflect any accessibility changes based on implementation of the build project.

Attributes or Assumptions	CMAP GO TO 2040 2008 Evaluation	IDOT I-290 EIS Model 2012 Evaluation	Comments
Specific Regional Travel Model Improvements			
1. Trip Generation Model (2009-2010)	Previous trip generation model calibration data based on information from1989-1991 Household Survey and 2000 Census Journey to Work data.	Updated CMAP regional trip generation rates based on more recent 2007-2008 CMAP Travel Tracker Survey and U.S. Census Bureau American Community Survey data. This included an update of trip generation rates for persons residing in households, stratification by income level for home-based work trips, and updates of the household vehicle ownership, trip attraction allocation, external trips, and non-motorized sub-models	I-290 improvements implemented by CMAP
2. Trip Distribution Model (2009-2010)	Previous trip distribution model calibration data based on information from 1989-1991 Household Survey and 2000 Census Journey to Work data.	Re-calibrated CMAP regional trip distribution models to more recent CMAP Travel Tracker Survey and Census journey to work trip length data. Updated the input files for estimating the costs of transit and highway travel, and stratified home based work trips by income level.	I-290 improvements implemented by CMAP
3. Mode Choice Model (2009-2010)	Previous mode choice model calibration data based on information from 1989-1991	Updated CMAP regional mode choice model, including re-calibration of the model	I-290 improvements implemented by CMAP

	Household Survey and 2000 Census Journey to Work data.	based upon more recent CMAP Travel Tracker Survey mode shares, update of travel costs to reflect current conditions, adjustment of model coefficients for current dollars in the primary auto-transit choice model and the auto occupancy sub-model, and model code revisions to account for the stratification of home-based trips by income level (for example, this stratification improves transit mode choice modeling for commuter rail and other longer distance commuting trips).	
4. Highway Assignment (2009-2010)	Previous highway assignment time-of-day model calibration data based on information from 1989-1991 Household Survey and 2000 Census Journey to Work data. Highway assignment by auto occupancy level not performed in regional CMAP model runs.	Updated CMAP regional highway trip assignment model, including updates to more current time-of-day factors based on the more recent CMAP Travel Tracker Survey, and revisions to the traffic assignment macros to include the assignment of the additional managed lane trip types.	I-290 improvements implemented by CMAP
5. Sub-Area Highway Network (2009-2010)	N/A	Added highway network detail in CMAP regional highway network for the I-290 study area to allow the development of more detailed project level traffic forecasts required for design purposes.	I-290 project specific model improvement

6. Sub-Area Zone System (2009-2010)	N/A	Added detail to transportation analysis zones in CMAP regional model for the I-290 study area to allow the development of more detailed project level traffic forecasts for design purposes.	I-290 project specific model improvement
7. Evaluation Measure Summaries (2009-2012)	N/A	Developed processes to summarize regional model data into transportation system performance evaluation measures. The summaries allowed IDOT to prepare the evaluation results of alternatives in a tabular format for use in comparing the transportation performance of different alternatives.	I-290 project specific model improvement
8. Highway Assignment (2011)	Equilibrium traffic assignment	Incorporated advanced path-based traffic assignment resulting in improved model convergence, faster computer run times, and the ability to analyze path-based results that are required for the development of travel performance summaries.	Implemented by CMAP
9. Trip Distribution/Mode Choice Models (2011)	Previous trip distribution/mode choice model cost data based on updates during mid-2000s	Revised CMAP procedure for estimating transit cost and time inputs for trip distribution and mode choice, including updating the fare calculations to current levels. These revisions were made to better reflect current transit	Implemented by CMAP

		conditions to provide faster computer run times.	
10. Transit Assignment (2011)	CMAP uses a variant of this transit assignment procedure	Implemented transit assignment procedure that does not require coding of auto access links and allows riders to consider multiple rail stations and bus stops. This results in improved sensitivity of the transit modeling through better transit access representation.	
11. Highway Assignment (2012)	Toll links contained in CMAP network	Updated tolling procedures in regional highway assignment through network coding, updated link volume-delay functions and revised assignment macros. This update improved the sensitivity of the model to tolling characteristics contained in the managed lane alternatives.	CMAP Implementation planned in 2013
12. Mode Choice Model (2012)	Tolls not included in CMAP Mode Choice Model	Developed a post-processing procedure that estimates the effect upon mode choice of alternate tolling and pricing scenarios. This results in the mode choice model being sensitive to tolling, so its impacts can now be reflected in the transit mode share.	CMAP Implementation planned in 2013

1.0 Background

This memo describes the proposed process for the Environmental Justice (EJ) assessment for the I-290 Study and includes some of the results of the analysis, which are summarized in the Draft Environmental Impact Statement (DEIS). The goal of an EJ assessment is to evaluate a proposed federal project based on potential disproportionately high and adverse impacts to minority and low-income populations and make provisions so that those groups are treated fairly during, and can participate in, decision-making processes related to proposed federal projects. To guide federal agencies in achieving this goal, Executive Order 12898 was issued entitled: "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," on February 11, 1994.

The Executive Order states that "each Federal agency shall make achieving EJ part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Pursuant to the Executive Order, the Federal Highway Administration (FHWA) has adopted FHWA Order 6640.23A, "FHWA Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," dated June 14, 2012.

FHWA Order 6640.23A defines the term "adverse effects" to include "the totality of significant individual or cumulative human health or environmental effects, including interrelated social and economic effects," which may include, but are not limited to: bodily impairment, infirmity, illness, or death; air, noise, and water pollution and soil contamination; destruction or disruption of human-made or natural resources; destruction or diminution of aesthetic values; destruction or disruption of community cohesion or a community's economic vitality; destruction or disruption of the availability of public and private facilities and services; vibration; adverse employment effects; displacement of persons, businesses, farms, or nonprofit organizations; increased traffic congestion, isolation, exclusion or separation of minority or low-income individuals within a given community or from the broader community; and the denial of, reduction in, or significant delay in the receipt of benefits of FHWA programs, policies, or activities.

In terms of transportation policy, the EJ framework contains three fundamental principles:

1. To avoid, minimize, or mitigate disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority and low-income populations;

2. To ensure full and fair participation by all potentially affected communities in the transportation decision-making process; and

3. To prevent the denial of, reduction in, or considerable delay in the receipt of benefits by minority and low-income populations.[1]

Under FHWA Order 6640.23A, a minority is defined as a person who is:

- **Black:** A person having origins in any of the black racial groups of Africa;
- **Hispanic or Latino:** A person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race;
- **Asian American:** A person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent;
- **American Indian and Alaskan Native:** A person having origins in any of the original people of North America, South America (including Central America) and who maintain cultural identification through tribal affiliation or community recognition; or
- **Native Hawaiian or Other Pacific Islander:** A person having origins in any of the original peoples of Hawaii, Guam, Samoa, or other Pacific Islands.

Under FHWA Order 6640.23A, low income is defined as a person whose median household income is at or below the Department of Health and Human Services poverty guidelines.

2.0 Defining Environmental Justice Populations in the Study Area

For this assessment, the data has been aggregated as White, Black, Asian, and Other. The Other category represents the sum of several US Census classifications, including American Indian and Alaskan Native, Native Hawaiian and Pacific Islander, Other Races, and those identified by two or more races.

As presented in FHWA Order 6640.23A, Hispanic or Latino populations are classified as a minority group, regardless of race. Consistent with the US Census data, Hispanic or Latino origins are considered as ethnicity data and a separate designation from race data.

According to the US Census Bureau, the terms "Hispanic" or "Latino" refer to persons who trace their origin or descent to Mexico, Puerto Rico, Cuba, Spanish speaking Central and South America countries, and other Spanish cultures. Origin can be considered as the heritage, nationality group, lineage, or country of the person or the person's parents or ancestors before their arrival in the US. People who identify their origin as Hispanic

[1] FHWA, 2000. http://www.fhwa.dot.gov/environment/environmental_justice/

or Latino may be of any race, consistent with the FHWA Order 6640.23A. Thus, the percent Hispanic was not added to percentages for racial categories.

Under FHWA Order 6640.23A, low-income is defined as a person whose median household income is at or below the US Department of Health and Human Services (HHS) poverty guidelines.

Compliance with EJ requirements is evaluated by identifying and assessing potential impacts to minority and low-income populations within the identified Study Area.

As defined by the US Census Bureau, census block groups generally contain between 600 and 3,000 people, and usually cover a contiguous area that does not cross state, county, or census tract boundaries. In conducting these assessments, available data for census block groups on population demographics is taken from the US Census and other sources.

For the purpose of comparison, there are two geographic units analyzed. The first, the affected community (AC), is defined as any census block group that is overlapped by the Study Area. The second, the Community of Comparison (COC), is a larger geographic unit that contains all of the alternatives; for the purposes of this study – it is Cook County, Illinois.

2.1 Determination of Meeting the Minority or Low-income Threshold

To identify concentrated racial and ethnic minority and low-income populations, 2010 Census block groups that met the following threshold criteria were classified as an EJ population of concern:

- If the AC population is more than 50 percent minority, ethnicity or low-income, or
- If the percentage of low-income, ethnicity or minority population in the AC is 10 percent greater than the percentage of low-income, ethnicity, or minority population in the COC.

2.2 Output of Environmental Justice Definition

The output of the definition of EJ concentrations is a series of GIS-based maps and tables. Due to the length of the corridor, the corridor is subdivided for readability. There are three sets of maps (Appendices A, B, and C): 1) minority status; 2) Hispanic/Latino ethnicity status; and 3) low income status, with two shading types depending on if the AC population is 50 percent minority, ethnicity or low income or if it is 10 percent greater than that of the COC. These maps will also be used to define impacts in the EJ section of this Environmental Impact Statement (EIS). Demographic tables will accompany the maps quantifying 2010 US Census population data.

3.0 Describing the Engagement of Environmental Justice Populations

In addition to analysis related to the EJ impacts of the proposed project, a component of EJ is the inclusion of EJ populations in the project planning process. As will be shown through the analysis in the EIS, EJ AC's are densely populated throughout the Study Area. To attempt to reach a diverse population throughout the Study Area, public meetings and other engagement tools have been used. To encourage participation, different engagement methods were employed and are documented in the I-290 EIS.

4.0 Methodology for Analyzing and Describing Potential Impacts to Environmental Justice Populations

The build alternatives being evaluated in the I-290 EIS include capacity and lane management improvements on the mainline of I-290, interchange modifications, and other multimodal improvements. The EJ analysis considers these improvements in determining impacts. The following table presents the analysis undertaken by type in the EIS.

Table 1. Environmental Justice Analysis by Impact Type

Impact Type	Review Element	Methodology/Measure
Mobility	Are interchange modifications providing consistent benefits/impacts throughout the Study Area? Does the design change access to/from residences or businesses?	Evaluate any right-of-way and traffic impacts of interchanges/cross roads as compared to the No Build Alternative. Since the interchanges are the same for all alternatives, the new interchange designs are compared with the 2040 No Build Alternative design.
Mobility	Does the occupancy requirement or cost of toll cause low income users to travel in more congested lanes, thereby increasing travel time?	Review travel time output from the travel demand model. This was done by reviewing trip tables at the transportation analysis zone level – and evaluating travel times. A series of maps was developed that compares all alternatives against the No Build Alternative for up to distinct EJ population origin and destinations versus overall changes in the Study Area to determine any disproportionate travel time impacts (Appendix D).

Impact Type	Review Element	Methodology/Measure
Mobility	Does the cost of toll in the build alternatives (if applicable) cause travelers to divert onto local system into low income/minority neighborhoods as compared to the No Build Alternative?	Trip table output from the travel demand model will give point to point travel data. This allows us to understand the level of diversion that occurs based on the alternative. Compare all alternatives against the No Build Alternative to determine diversion onto the local road network.
Mobility	Do any of the alternatives affect transit users, bicyclists and pedestrians in a disproportionate way?	Qualitatively discuss improvements being made to bicycle and pedestrian facilities. Discuss if project improvements are impacting these users more than auto users.
Safety	Does the cost of toll cause travelers to divert onto local system into low income/EJ neighborhoods (as compared to the No Build Alternative), which could pose a higher safety risk to neighborhood residents (bicycles, pedestrians and local drivers)? Will the alternatives impact (positive or negative) emergency response times to the AC/EJ populations as compared to the No Build Alternative?	Compare all alternatives against the No Build Alternative to determine traffic diversion onto the local road network from travel model. If significant traffic changes, determine impacts to safety and response times. Review national research on HOT/toll lanes relative to HOT/toll lane usage versus income.
Other	Do any of the alternatives of the proposed project result in disproportionately adverse environmental effects in EJ communities?	Reiterate project impacts in the following environmental disciplines: Noise, Air quality, Section 4(f), Relocations, Public Services and Utilities, Land Use, Visual, Economic, and Cultural Resources. Where adverse effects are anticipated, discuss if these effects are concentrated in areas that have a higher percentage of EJ and low-income populations. There would be "disproportionately high and adverse" effects if, for example, all project-related noise impacts are concentrated in EJ communities.

5.0 Summary of Environmental Justice Findings

There are minority and low-income EJ Populations in the Study Area. The project was examined to identify any disproportionately high adverse human effects on these

populations, to ensure that participation in the transportation decision-making process was full and fair, and to ensure that project benefits would be received by EJ communities in an equitable and timely manner.

To measure the effects, access to employment, non-motorized transportation and transit access to and from I-290 between 1st and 25th Avenues, and traffic effects on neighborhood arterials were examined from a transportation standpoint. Also, social and environmental factors such as community changes, noise, air quality, and historic properties were examined for disparate impacts between the EJ and non-EJ communities served by the project. The public involvement/community outreach efforts were identified, both as to location, frequency, and method of delivery.

No substantial differences in transportation access were found with any of the build alternatives with respect to EJ communities, as compared to non-EJ communities, and all build alternatives had benefits in job accessibility and non-motorized and transit access for EJ communities that were similar to non-EJ communities. Of the build alternatives, the HOT 3+ & TOLL alternative had a worse impact on 2040 arterial traffic than the No Build Alternative, while the other three build alternatives showed positive effects. Environmental effects such as those to air, noise, and social and economic resources (including construction impacts) were similar for both EJ and non-EJ communities, and no residences or businesses in either EJ or non-EJ communities are proposed to be displaced by any of the build alternatives. Public involvement was encouraged by the participation of representatives of EJ communities in the project's CAG study group, as well as traditional and non-traditional means of engaging the public in participation at public and community meetings. Though there will be impacts (noise and construction impacts in particular) to EJ and non-EJ communities along the Study Area, upon implementation of the planned mitigation, as described in this EIS, and coordinated with each community, the impacts will not be disproportionately high and adverse to EJ communities.

Appendix A

Minority Populations

Minority Populations

Black/African American Populations

The geographic dispersion of Black/African American communities is presented in Figure 1. The Project Corridor for the I-290 Study consists of 167 census block groups. Of these 167 block groups, 98 have Black/African American populations that are 50 percent or more of the block group total or have Black/African American populations at least 10 percent higher than the Cook County average (24.6 percent). These block groups can be classified as EJ Populations.

Black/African American populations are the most predominant minority community within the Study Area, making up 33.4 percent of the Study Area population, according to the US Census Bureau 2013 estimates. The Study Area total of Black/African Americans is higher than the Cook County average of 24.6 percent.

One of the largest concentrations of Black/African American populations is in the eastern portion of the Study Area in the City of Chicago, primarily between Austin Boulevard and Ashland Avenue. Other concentrations of Black/African American populations are located in the western half of the Project Corridor, north of I-290 in Maywood and Bellwood, and south of I-290 in Broadview.

Asian Populations

Thirteen block groups have Asian populations that are 50 percent or more of the block group total or have an Asian population at least 10 percent higher than the Cook County average (6.2 percent). These block groups can be classified as EJ Populations.

The geographic distribution of Asian populations can be seen in Figure 2. The largest concentration of Asian populations in the Project Corridor is found in Chicago between Damen Avenue and Ashland Avenue. Other areas of Asian populations that are 10 percent or greater than the Cook County average are found in Chicago, south of West Harrison Street, between Western and Ashland Avenues. The Village of Westchester also has an Asian population that is 10 percent greater than the Cook County average located between Wolf Road and US Route 45.

Some Other Race

According to the US Census Bureau the 'Some Other Race' category includes all other responses not included in the 'White', 'Black or African American', 'American Indian and Alaska Native', 'Asian' and 'Native Hawaiian and Other Pacific Islander' race categories described above. Respondents providing write-in entries such as multiracial, mixed, interracial, or a Hispanic/Latino group (for example, Mexican, Puerto Rican, or Cuban) in the 'Some Other Race' category are included in the Some Other Race classification.

In the Project Corridor, there are concentrations of 'Some Other Race' populations dispersed across the corridor. As depicted in the Figure 3, most of the 'Some Other Race' populations are outside the EJ study area. The largest concentrations of 'Some Other

Race' populations are located in Cicero between Ridgeland Avenue east to Kostner Avenue, and from Roosevelt Road south to Cermak Road. Another concentration is located along Cermak Road in Chicago from Ashland Avenue east to I-94. Census block groups with populations of 'Some Other Race' that are 10 percent or greater than the Cook County average are also located in Maywood, Bellwood and Hillside in the western portion of the Project Corridor.

Of the 167 total block groups of the project area, 14 block groups had populations of individuals identifying themselves as 'Some Other Race' that made up 50 percent or greater than the block group's total population or are 10 percent higher than the Cook County Average. These block groups can be classified as EJ Populations.

Two or More Races Populations

Within the 167 block groups of the Project Corridor, there is one block group that is an EJ Population, because it has a population identifying as Two or More Races that was 10 percent higher than the Cook County average (1.8 percent) (Figure 4). This area is located north of Cermak Road, approximately between Ashland Avenue and Racine Avenue in Chicago.

Minority Populations

Block groups in the Project Corridor that are composed of 50 percent or more minority populations make up the majority of the block groups assessed. Of the 167 total block groups in the corridor, 109 contain 50 percent or greater minority populations, equating to 65.3 percent of all the block groups in the project corridor. The geographic dispersion of minority populations in the Project Corridor is detailed in Figure 5 through Figure 8. The maps show majority minority census block groups throughout the Project Corridor. The exceptions are largely in the far eastern portion of the Project Corridor in Chicago, the Villages of Oak Park, Forest Park, and River Forest.

Appendix B

Hispanic/Latino Ethnicity Populations

Hispanic/Latino Populations

Figure 9 through Figure 12 depict the geographic dispersion of Hispanic/Latino block groups along the Project Corridor that either make up 50 percent of the block group's population or are 10 percent or greater than the Cook County Hispanic/Latino population average. Of the 167 block groups assessed in the Project Corridor, 16 were found with Hispanic/Latino populations making up 50 percent or more of the block group's total population.

The largest concentration of Hispanic/Latino populations is located in Cicero and Berwyn along Roosevelt Road. This area extends from Cicero Avenue west to approximately Oak Park Avenue in Berwyn. Hispanic/Latino populations making up 50 percent or more of the population are also located along Douglas Boulevard south to 16th Street and from Kedzie Avenue west to Central Park Avenue.

Figure 9. I-290 Hispanic/Latino Ethnicity Status (Sheet 1)

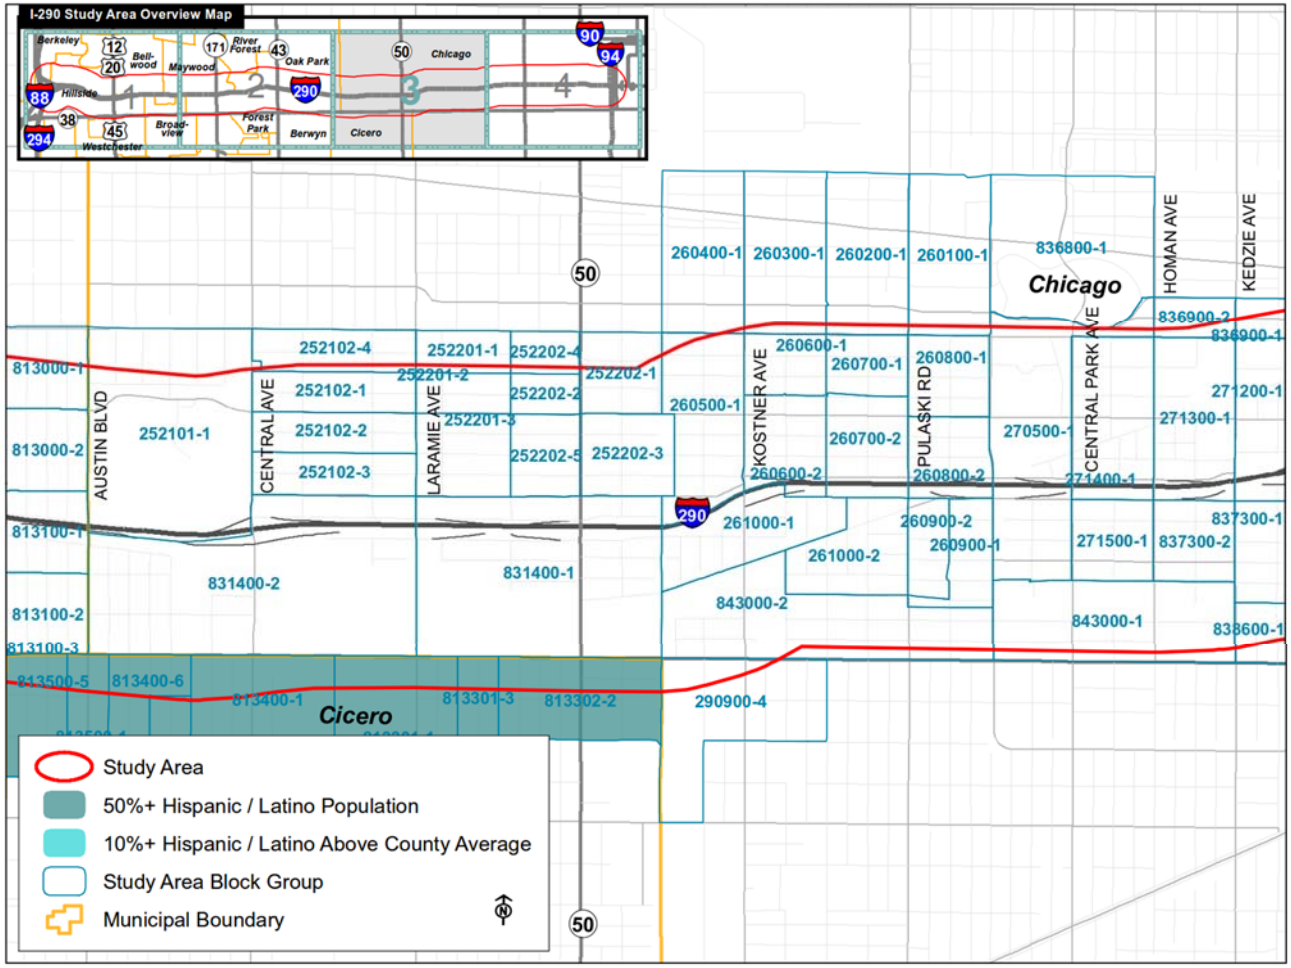

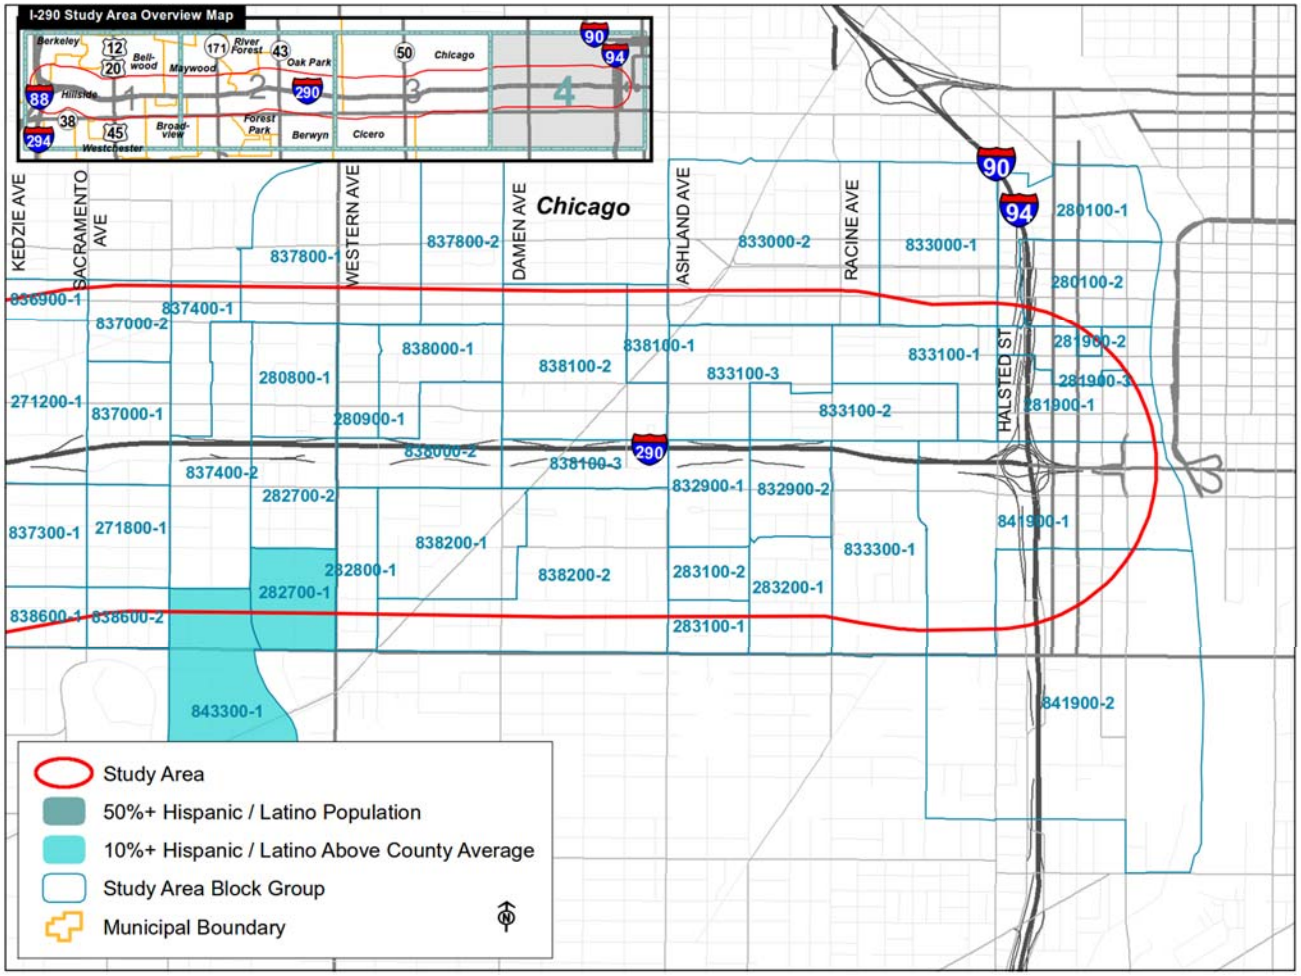

Figure 12. I-290 Hispanic/Latino Ethnicity Status (Sheet 4)

Appendix C

Low-Income Populations

Low-Income Populations

Data assessing low-income population was gathered from the 167 census block groups that are within the Project Corridor. These block groups can be classified as EJ affected communities based on low-income status as defined in the EJ Methodology Memorandum found in Appendix D.

There are 65 block groups that are made up of 50 percent or more low-income residents or are 10 percent higher than the Cook County Average (15.8 percent). These are considered block groups with EJ Populations.

The geographic dispersion of low-income population is shown in Figure 13 through Figure 16. The greatest concentration of low-income populations that are either 10 percent higher than the Cook County average, or block groups with a total population 50 percent or higher low-income, are found in the Chicago portion of the Project Corridor from Austin Boulevard to the I-90/I-94 corridor. Two of the greatest concentrations of low-income populations are found near the intersection of I-290 and Kostner Avenue in Chicago as well as Ashland Avenue to Roosevelt Road. Another area of low-income residents is found along Central Park Avenue from Madison Street south to Roosevelt Road. Most of the block groups found to have populations that are 50 percent or greater of the total population are within the 0.5 mile Project Corridor.

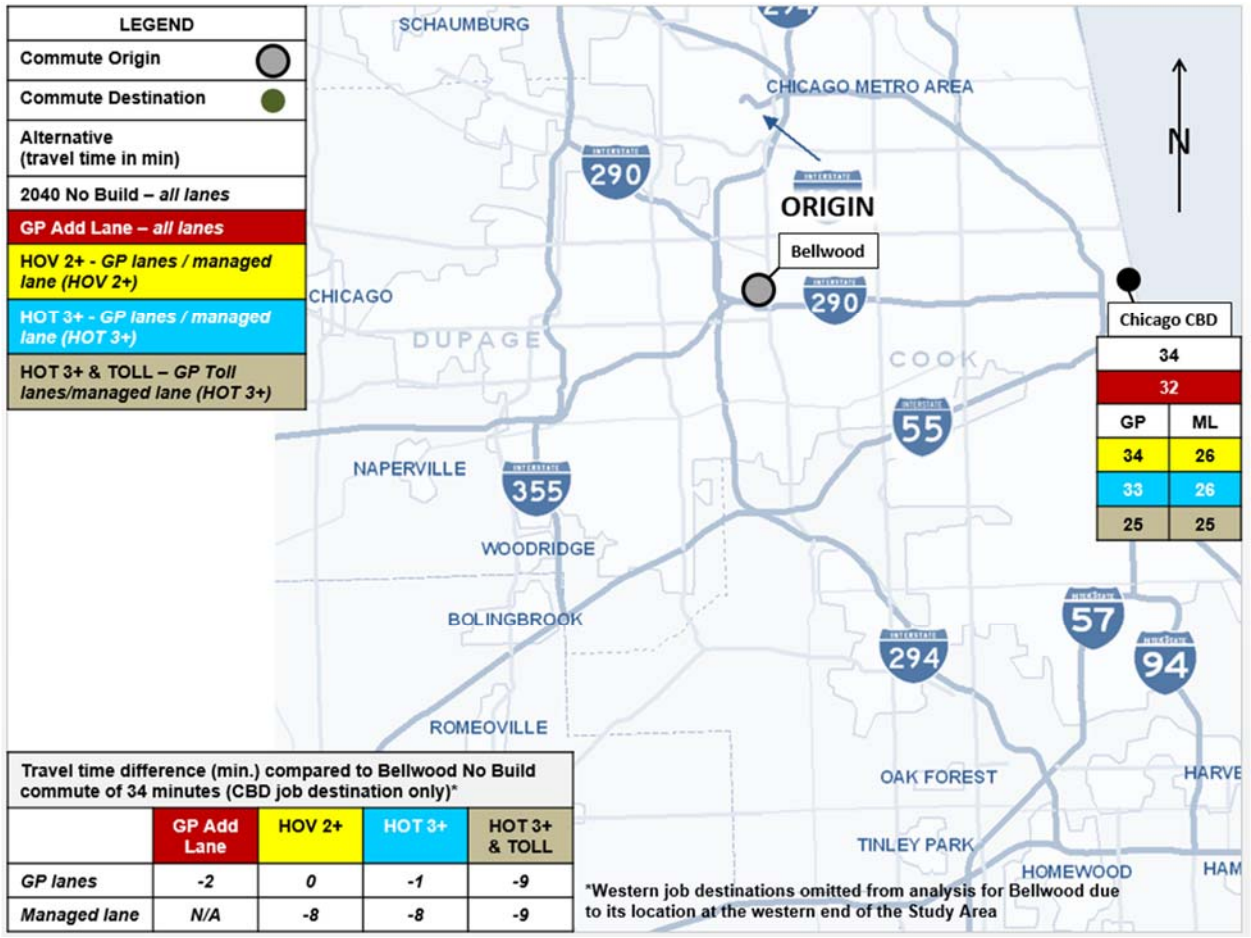
Appendix D

Accessibility to Employment Centers

Access to Employment Centers

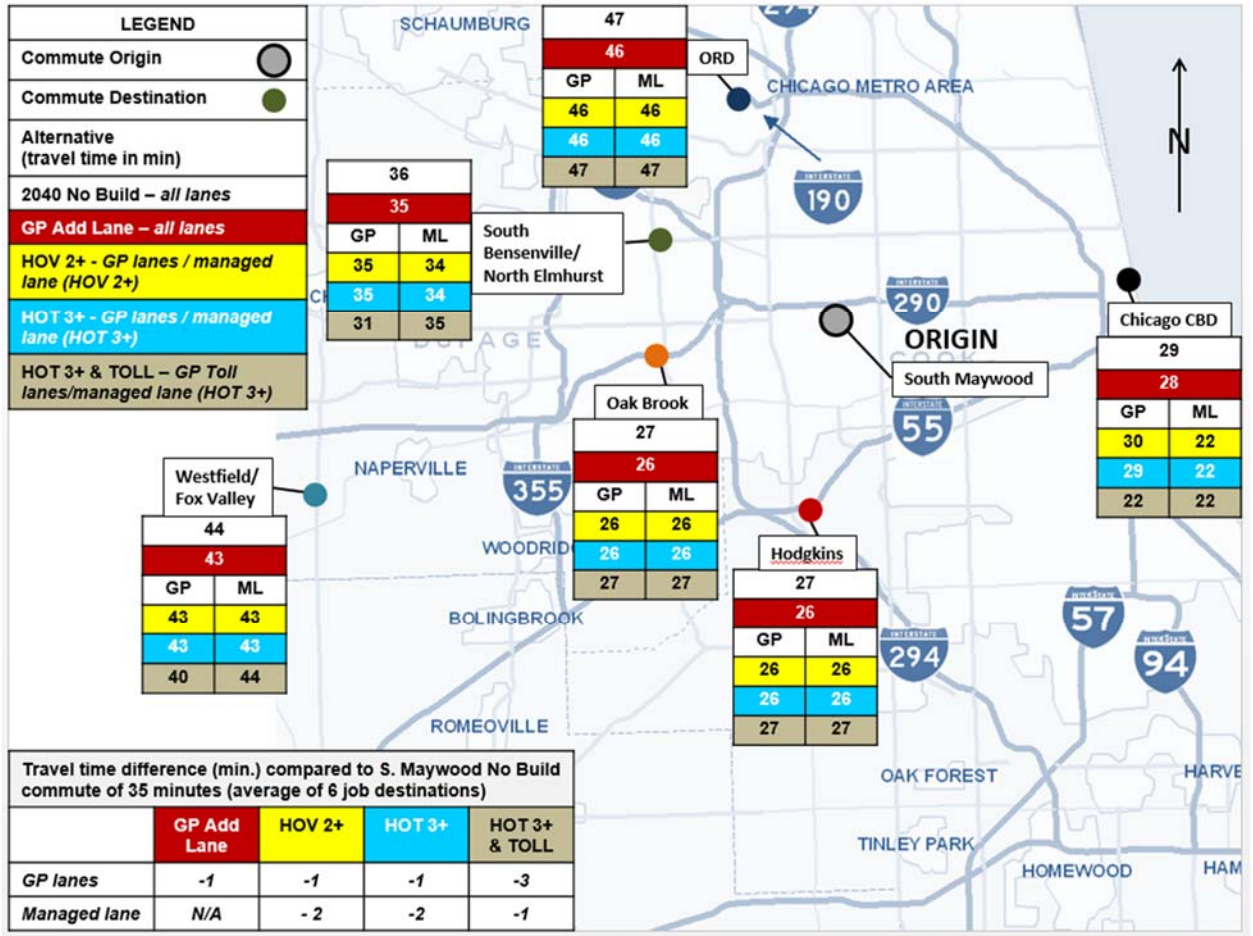
All of the build alternatives offer increases in average travel speed on I-290 through the length of the Project Corridor in the AM and PM Peak periods when compared to the 2040 No Build Alternative. The improved speeds on the expressway relative to the 2040 No Build Alternative would be a benefit to EJ populations since they would be able to travel to and from their destinations more quickly.



An additional analysis of access to employment centers was completed by comparing travel times from different origin and destination (O/D) pairs in the Study Area for all the build alternatives. For this analysis, the study's travel demand model was used. Trips were estimated in Transportation Analysis Zones (TAZs) within communities that have high EJ Populations as well as TAZs within communities that do not have a high EJ component. Five representative EJ communities (Bellwood, South Maywood, North Maywood, and the Chicago neighborhoods of West Garfield Park and East Garfield Park) as well as two representative non-EJ communities (Forest Park and Oak Park) were studied, with a job trip origin at a central location within each community and job trip destinations at the Chicago Central Business District and five representative suburban employment cluster locations (O'Hare Airport-ORD, South Bensenville/North Elmhurst, Oak Brook, Hodgkins, and Westfield/Fox Valley).

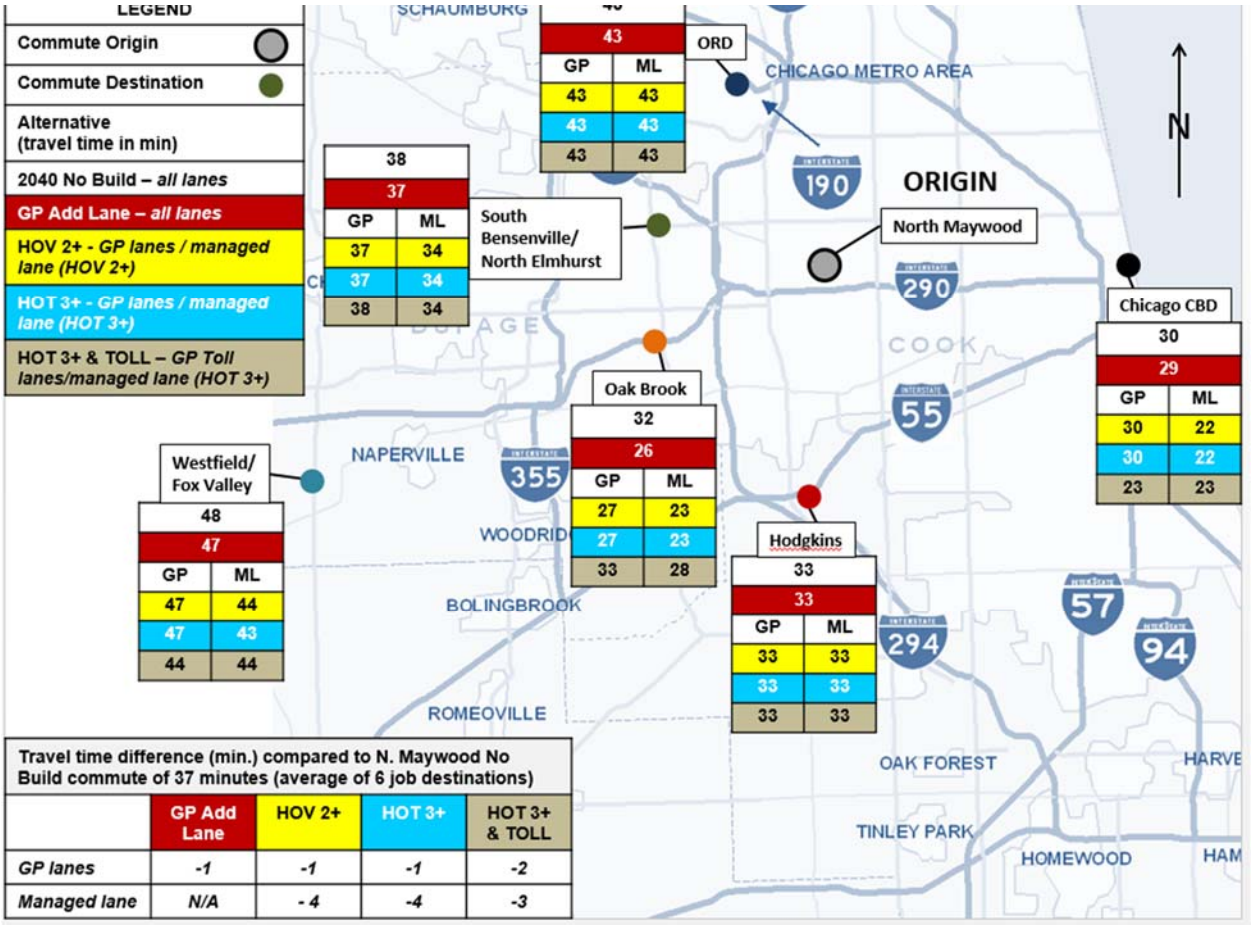
For Bellwood, only trips to the Central Business District were studied, since Bellwood's location at the west end of the Study Area would require minimal usage of the proposed I-290 build alternatives by employees accessing the suburban job locations.

Within each alternative, there are no apparent accessibility differences in travel times between the EJ and non-EJ communities. As shown in Figure 17 through Figure 23, the travel times are primarily a function of the distance from the trip origin to the destination and the efficiency of the alternative and lane in addressing mobility. Therefore, there is no overall discrepancy in potential mobility between EJ and non-EJ communities within any of the alternatives. However, the HOT 3+ & Toll Alternative is the most restrictive alternative with a requirement of three or more occupants to qualify for toll-free access to I-290. The other managed lane alternatives offer three free, unrestricted lanes and a fourth lane that can be accessed with no toll for vehicles meeting the occupancy requirements of two to three persons.



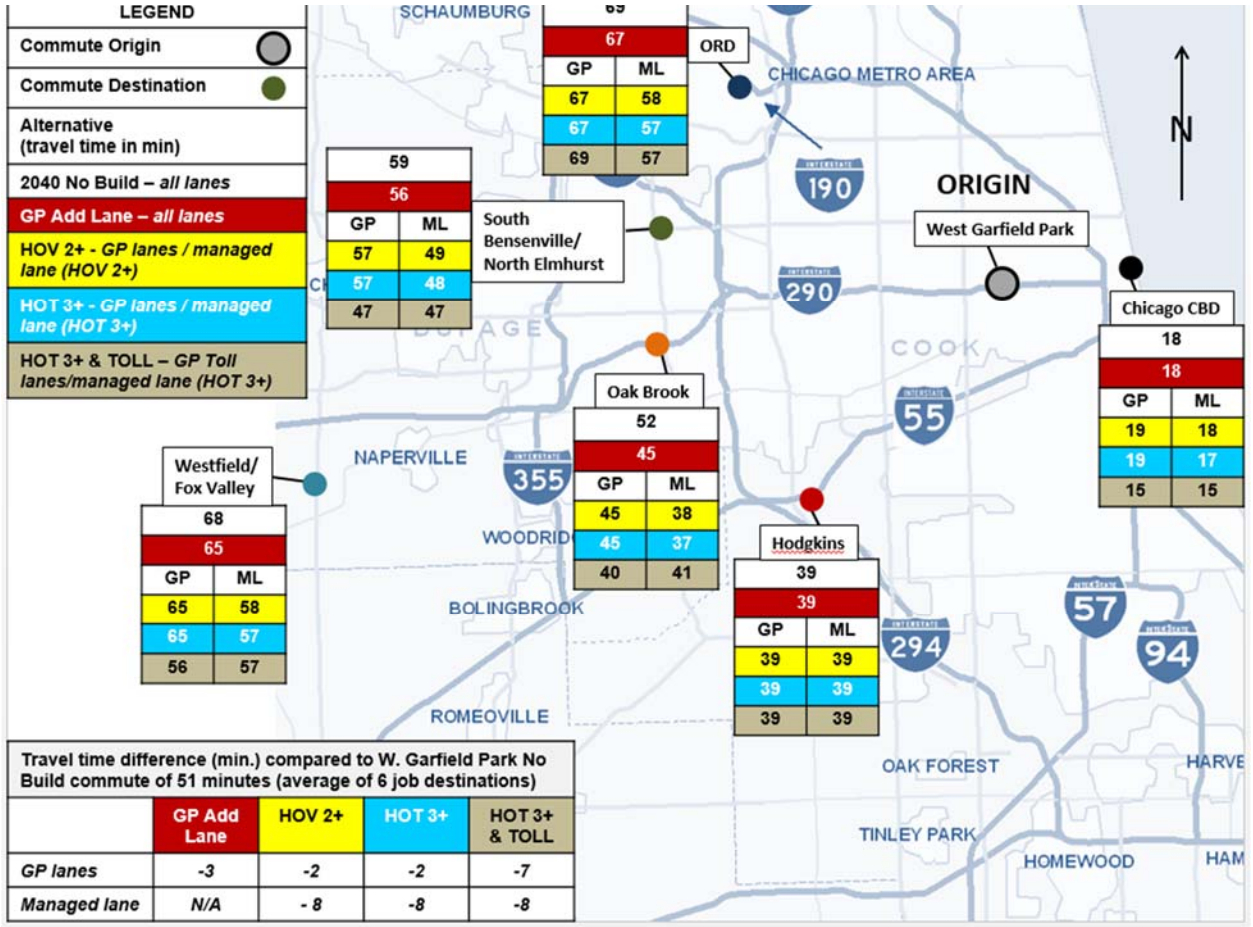
EJ Communities

Figure 17. Travel Times between Bellwood and Employment Destinations



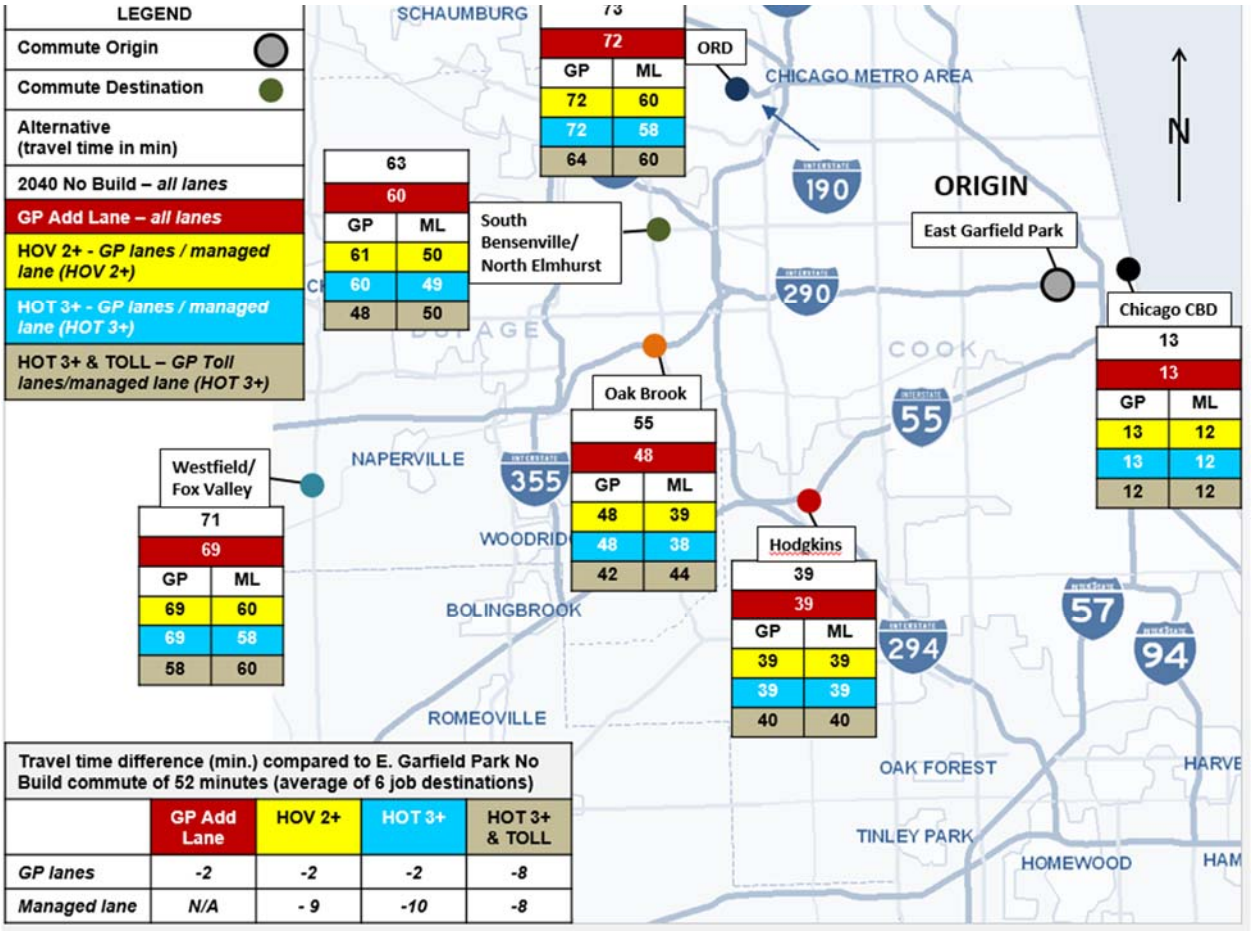
Bellwood: Commute travel times to Chicago CBD with the build alternatives range from 2 to 9 minutes less (GP or GP Toll lanes) and 8 to 9 minutes less (managed lanes) than those of the No Build Alternative, depending on alternative and lanes used. The GP lanes of the HOV 2+ Alternative offer the least time savings (0 minutes) and the HOT 3+ & TOLL Alternative's GP Toll and managed lanes offer the highest time savings (-9 minutes). As stated previously, destinations other than Chicago CBD were not studied for this trip origin due to its location at the western end of the Study Area and minimal potential travel on I-290 to suburban "reverse commute" job destinations.

Figure 18. Travel Times between South Maywood and Employment Destinations



South Maywood: Commute travel times to job destinations with the build alternatives range from 1 minute more to 7 minutes less (GP or GP Toll lanes) and 0 to 7 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 1 to 3 minutes less than the No Build Alternative, with all lanes of the GP Add Lane Alternative, the GP lanes of the HOV 2+ and HOT 3+ alternatives, and the managed lane of the HOT 3+ & TOLL Alternative offering the least time savings (-1 minute) and the GP Toll lanes of the HOT 3+ & TOLL Alternative offering the highest time savings (-3 minutes).

Figure 19. Travel Times between North Maywood and Employment Destinations



North Maywood: Commute travel times to job destinations with the build alternatives range from 0 to 7 minutes less (GP or GP Toll lanes) and 0 to 9 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 1 minute to 4 minutes less than the No Build Alternative, with all lanes of the GP Add Lane Alternative and the GP lanes of the HOV 2+ and HOT 3+ alternatives offering the least time savings (-1 minute) and the managed lanes of the HOV 2+ and HOT 3+ alternatives offering the highest time savings (-4 minutes).

Figure 20. Travel Times between West Garfield Park and Employment Destinations

West Garfield Park: Commute travel times to job destinations with the build alternatives range from 1 minute more to 12 minutes less (GP or GP Toll lanes) and 0 to 12 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 2 to 8 minutes less than the No Build Alternative, with the GP lanes of the HOV 2+ and HOT 3+ alternatives offering the least time savings (-2 minutes) and the managed lanes of the HOV 2+, HOT 3+, and HOT 3+ & TOLL alternatives offering the highest time savings (-8 minutes).

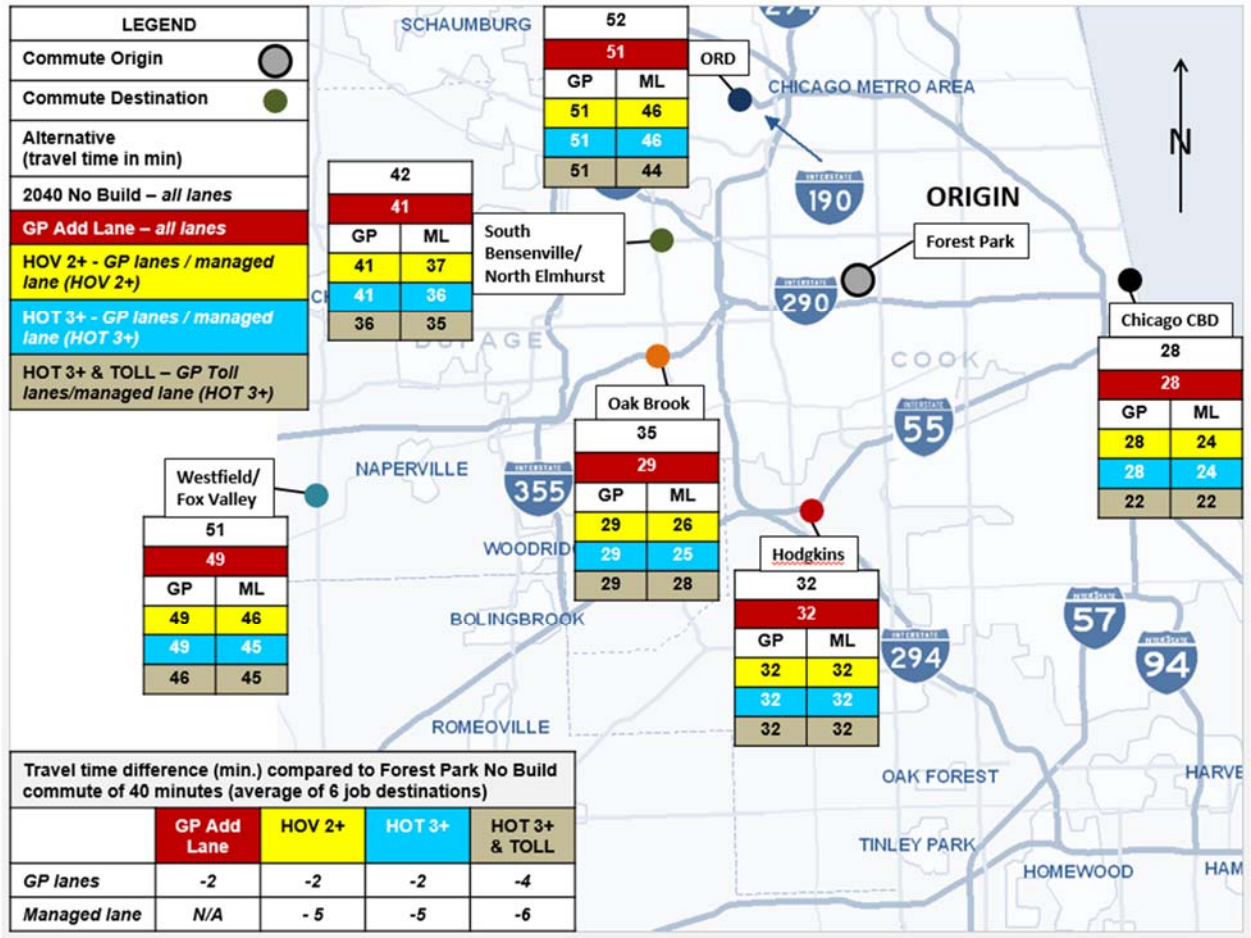


Figure 21. Travel Times between East Garfield Park and Employment Destinations

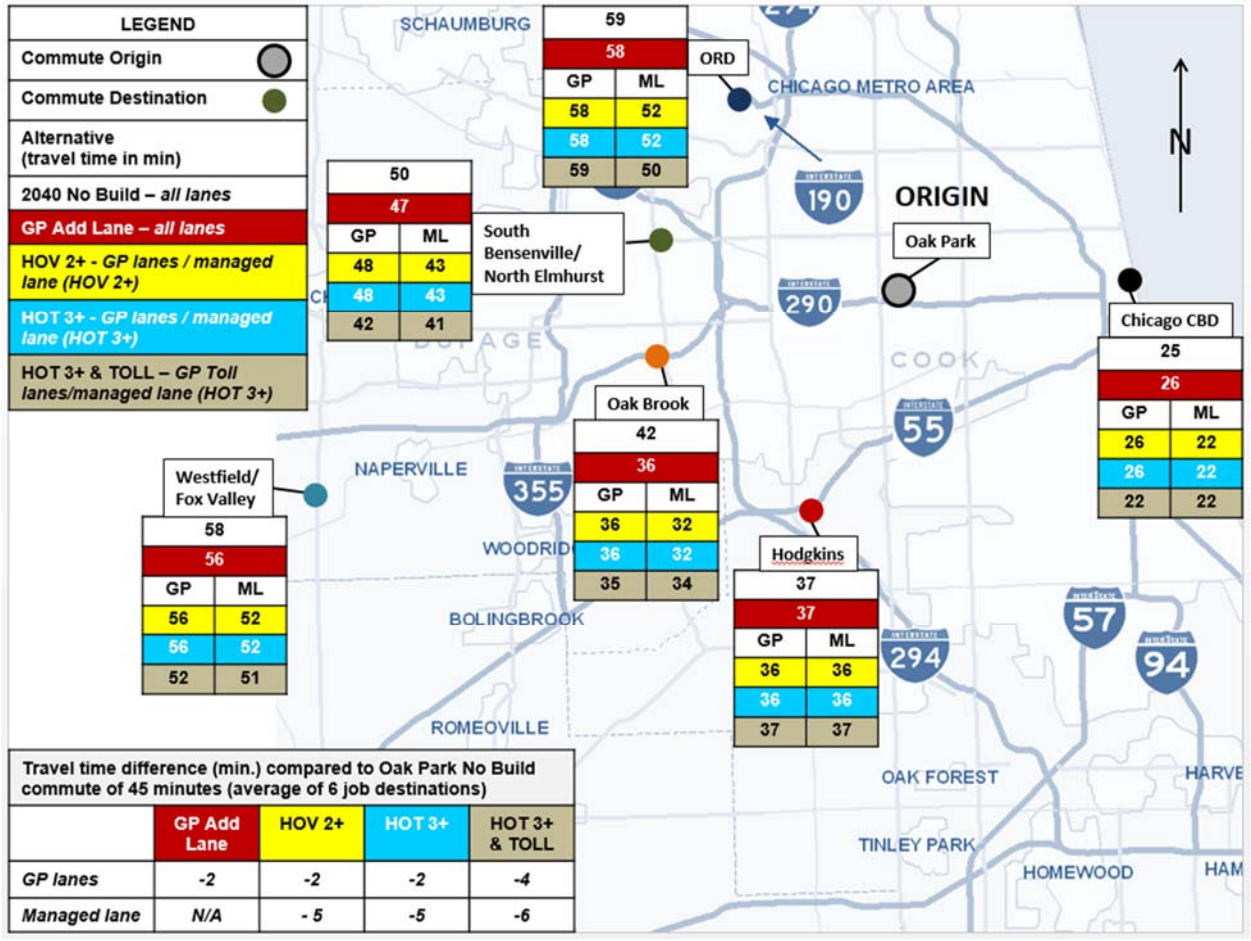
East Garfield Park: Commute travel times to job destinations with the build alternatives range from 0 to 15 minutes less (GP or GP Toll lanes) and 0 to 17 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 2 to 10 minutes less than the No Build Alternative, with all lanes of the GP Add Lane Alternative and the GP lanes of the HOV 2+ and HOT 3+ alternatives offering the least time savings (-2 minutes) and the managed lanes of the HOT 3+ Alternative offering the highest time savings (-10 minutes).



Non-EJ Communities

Figure 22. Travel Times between Forest Park and Employment Destinations

Forest Park: Commute travel times to job destinations with the build alternatives range from 0 to 6 minutes less (GP or GP Toll lanes) and 0 to 10 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 2 to 16 minutes less than the No Build Alternative, with all lanes of the GP Add Lane Alternative and the GP lanes of the HOV 2+ and HOT 3+ alternatives offering the least time savings (-2 minutes) and the managed lane of the HOT 3+ & TOLL Alternative offering the highest time savings (-6 minutes).

Figure 23. Travel Times between Oak Park and Employment Destinations

Oak Park: Commute travel times to job destinations with the build alternatives range from 1 minute more to 8 minutes less (GP or GP Toll lanes) and 0 to 10 minutes less (managed lanes) than those of the No Build Alternative, depending on destination, alternative and lanes used. The average commute time to all job destinations is from 2 to 6 minutes less than the No Build Alternative, with all lanes of the GP Add Lane Alternative and the GP lanes of the HOV 2+ and HOT 3+ alternatives offering the least time savings (-2 minutes) and the managed lane of the HOT 3+ & TOLL Alternative offering the highest time savings (-6 minutes).

Summary

For eastbound commuting trips to the Chicago CBD, the build alternatives would generally offer more travel time savings for the EJ communities located farthest from the CBD (North and South Maywood and Bellwood), as compared to the nearby EJ communities of East and West Garfield Park. For the non-EJ communities of Forest Park and Oak Park, similar patterns are evident for trips to the CBD.

For westbound commuting trips (or reverse commute) to suburban employment cluster locations, the build alternatives would generally offer more travel time savings for the EJ communities located farthest from the suburban employment clusters (East and West Garfield Park) as compared to the nearer EJ communities of North and South Maywood. For the non-EJ communities of Forest Park and Oak Park, similar patterns are evident for trips to the suburban employment cluster locations. As both Oak Park and Forest Park are located toward the center of the Project Corridor, little difference in performance would be expected in the westward direction among the two communities.

The managed lanes of the HOV and HOT 3+ and HOT 3+ and TOLL alternatives generally offer the greatest commuting time savings, while general purpose lanes of all alternatives offer more modest time savings, and in some cases offer commuting times that are unchanged or slightly worse than the No Build Alternative. The tolled lanes of the HOT 3+ & TOLL Alternative also have relatively high time savings as compared to the No Build Alternative.

Appendix E

Section 106 Materials and Correspondence

I-290 Eisenhower Expressway
Cook County, Illinois

Since the publication of the DEIS, Appendix E was updated to include the following:

E-4 – Added SHPO no adverse effect concurrence letter

E-5 – Added March 29, 2017 SHPO no archaeological properties affected concurrence letter

E-6 – Added Park District of Oak Park letter about Effects Assessment Report and response

E-8 – Added Effects Assessment Report (April 2017)

E-9 – Added meeting materials and meeting summary for consulting parties meeting on Effects Assessment Report

Prepared For:

Illinois Department of Transportation
